It would be idle to pretend that any such relative efficiency has been attained in the brief period of the years between 1915 and 1922. Though we have in our ships many of the best officers in the world, our officers as a whole and on the average fall short of the experience of their European competitors. This is even more signally true of our crews. This is a handicap, however, which time itself will cure; in fact, any disparity on this point between Europeans and ourselves is even now rapidly lessening. I am one of those who believe that, given a fair chance, American officers and crews will gradually reestablish the supremacy which in the last century was theirs as the most capable men of their calling in the world.

American and British Wage Difference

The wage difference between American and British ships is somewhat less now than it has been of recent years, and must be regarded as temporary due to the abnormal condition of world shipping, but it is still a wide difference, as will be demonstrated by the following comparison of the costs of wages and subsistence of an American and a British cargo steamer of 3,500 gross tons, and the wages and subsistence of an American and a British cargo steamer of 6,000 gross tons:

Wage Comparison—American and British Oil-Burning Steamers, 3,500 Gross Tons

In the above comparison a similar number of crew in each vessel has been used, but it is a generally accepted fact that American vessels carry a greater number in the crew than do foreign vessels. This difference is more especially to be found in the "tramp," coastal or short-voyage American steamers as compared with the foreign vessels; while in the case of the passenger liners or cargo liners the British manning scale more nearly approximates our own. On the other hand, the manning scale of Continental European ships will generally be found to be less than the British.

Manning Requirements of American and British Ships

The manning requirements contained in the United States statutes as compared to the requirements contained in the British Merchant Shipping Act are illustrated.

Section 4463, United States Revised Statutes, provides that no vessel of the United States subject to United States laws shall be navigated unless she shall have in her service and on board such complement of licensed officers and crew, including certificated life boat men, as in the judgment of the local inspectors may be necessary for her safe navigation. An entry shall be made in the certificate of inspection covering the number of officers and men required.

A minimum manning scale for the officers is further contained in this section of the law which requires that every ocean or coastwise seagoing merchant vessel of the United States propelled by machinery and every ocean-going passenger vessel shall have a minimum number of licensed officers for the vessel's safe navigation according to the following scale:

"All such vessels shall have a licensed master.

"All vessels of 1,000 gross tons or over navigating on routes of more than 400 miles shall have three licensed mates.

"If the vessel is between 200 and less than 1,000 gross tons, two licensed mates are required.

"If the vessel is between 100 gross tons and less than 200 gross tons, one licensed mate; but if the time required to make the voyage from port to port exceeds 24 hours, two licensed mates shall be required."

There is a specific requirement in this section that the officers shall be divided into three watches, and under this

system the local inspectors require the same number of engineers as licensed deck officers.

The British Merchant Shipping Act is silent as to the number of unlicensed personnel required on board of a British ship, except in the case of emigrant ships, which may be considered as passenger liners in the transatlantic trade or the liners to India, Australia or South Africa. The crewing of these vessels will be dealt with later in this paper. As to the licensed officers, I wish to direct your attention to the fact that the requirements are not positive or mandatory in the full sense and state as follows:

"1. Every British foreign-going ship and every British home trade passenger ship, when going to sea from any place in the United Kingdom, and every foreign steamship carrying passengers between places in the United Kingdom, shall be provided with officers duly certificated under this Act according to the following scale:

"(*a*) In any case with a duly certificated master:

"(*b*) If a ship is of 100 tons burden or upwards, with at least one officer besides the master holding a certificate not lower than that of only mate in the case of a foreign-going ship, or of mate in the case of a home-trade passenger ship.

"(*c*) If the ship is a foreign-going ship, and carries more than one mate, with at least the first and second mate duly certificated.

"(*d*) If the ship is a foreign-going steamship of 100 nominal horsepower or upwards, with at least two engineers, one of whom shall be a first-class and the other a first-class or second-class engineer duly certificated.

"(*e*) If the ship is a foreign-going steamship of less than 100 nominal horsepower or a seagoing home-trade passenger steamship, with at least one engineer who is a first-class or second-class engineer duly certificated."

> *"Uncle Sam is not a Santa Claus. He is giving us no gift, no bonus, in this shipping legislation. All he does is to try to assure for us a fair, even chance in competition. A fair chance is something which we have not had for sixty or for seventy years. If this bill passes, we will have it, and then it will be up to us to make such use of it as was made by the shipowners, operators and builders of the brilliant half century before the Civil War. They were given a chance. They took it, and they made such glorious use of it that the maritime world has not yet forgotten the years when American ships embodied the highest efficiency and success the world had ever seen. What we will have to do now is to prove ourselves as good men as our predecessors in this industry."*—Eugene E. O'Donnell.

While it is acknowledged that most British ocean ships in the foreign trade carry as many licensed deck officers as American ships and frequently as many engineers, the character of the British legislation is such that they may reduce the number at any time and are not subject to the penalties for failure to carry the full quota, as happens in the case of American ships by virtue of the penalty clause contained in Section 4463.

With further reference to the unlicensed personnel on American ships, in addition to the authority reposed in the local inspectors which is contained in Section 4463, Section 2 of the Seaman's Act provides that the sailors while at sea shall be divided into at least two watches and the firemen, oilers and watertenders into at least three watches. The seamen may not be shipped for duty alternately in the fireroom and on deck, and the firemen may not be shipped to perform duty in the fireroom and on deck; while in the American ship on Sundays and holidays the crew shall not be permitted to perform unnecessary duties nor shall they be required to do duty on any week day of more than nine hours while the vessel is in a safe harbor. In this regard, let me again point out that the British law is silent.

Section 13 of the Seamen's Act requires that 65 percent of the deck crew shall be able-bodied seamen and to obtain a full-fledged A. B. seaman's certificate a man must have at least three years' experience on the deck of a vessel at sea.

Section 14 of the Seamen's Act relates to the life-saving equipment and the manning of boats and rafts with a definite number of licensed officers, able seamen and certificated lifeboat men. All boats and rafts carrying more than fifteen persons are required to be in charge of a licensed officer or able seaman. The British Merchant Shipping Act is silent on the question of watches at sea and as to the requirement of the number of able seamen. Only in the case of emigrant or passenger ships does it carry a schedule as to crew requirements.

Again I desire to direct your attention to the moderate terms of the language employed.

"1. Every emigrant ship shall be manned with an efficient crew for her intended voyage, to the satisfaction of the emigration officer from whom a certificate for clearance of such ship is demanded; after the crew have been passed by the emigration officer, the strength of the crew shall not be diminished nor any of the men changed without the consent in writing either of that emigration officer or of the superintendent at the port of clearance.

"2. Where the consent of a superintendent has been obtained, it shall, within twenty-four hours thereafter, be lodged with the said emigration officer."

The Board of Trade regulations, however, contain certain provisions with regard to the manning of lifeboats and rafts. These regulations are not as stringent as the requirements of Section 14 of the Seaman's Act. In the case of a British ship a certificated lifeboat man may take charge of a boat or raft, and this permits stewards and other petty officers to take charge and thereby lessens the requirements as to the number of able seamen.

If American ships were everywhere in the majority in overseas trades, the wage difference might not be so heavy a handicap as it is at present. It is the foreign ships that are far more numerous, and their managers and operators are intrenched in position as ours are not. In order to develop our own merchant marine, we must take a part of their present trade away from our enterprising foreign competitors. I need not point out that it is difficult to do this with ships confined to a relatively few types, maintained at substantially higher costs for wages and subsistence.

National Assistance Absolutely Necessary

There is only one way in which the result which we all seek can be accomplished, and that is by national assistance such as has been recommended to Congress by the American Steamship Owners' Association and the United States Ship Operators' Association in the representations which they have recently made to the Congress of the United States.

It is a matter of regret that our inspection requirements do not make it obligatory that licensed engineers have an adequate shop training. It is more and more manifest that this is needed to reduce repair bills and maintain engine and boiler efficiency.

As to the firemen in coal-burning steamers, we have a present good supply, but relatively few of them are American citizens. The present shipping subsidy bill will certainly contain a stiff requirement of citizenship for the unlicensed members of the crew, at least in the deck and engine departments, and it is a question how such a requirement can be met in coal-burning firerooms. On oil-burning steamers a

large force of citizen firemen, most of them young men, is developing.

One of our greatest present deficiencies is in masters of the requisite business training and experience for the overseas trade. Many excellent captains, good navigators, seamen and executives, have passed most of their careers in the coastwise or near-by trade and are having their first experiences with the purely business problems that present themselves in the distant ports of foreign commerce. It is desirable also that the chief mates of our foreign-going steamers, some of whom will soon succeed to command, should acquire as soon as possible a knowledge of business as it is conducted overseas.

I am of the opinion that a shipping subsidy law should not require an American percentage of more than forty, to begin with, in the deck and engine departments. It might follow in this respect the graduated increase in the proportion of able seamen as provided for in the La Follette seamen's law. To develop what is apparently expected by Congress and the country in the form of an unlicensed seagoing personnel, the greater part American, will require close study and patient effort on the part of owners and operators of steamers in the merchant marine, and could best be obtained through a system of naval reserve training.

> *"So long as any usable part of the government-owned fleet remains in the possession of the Government it will act as a damp blanket on the hopes and plans of American shipowners and operators and also American shipbuilders. There is good reason to believe that, if the now proposed Shipping Bill is enacted, a very large proportion of the good Shipping Board tonnage can be disposed of within two years. American owners and operators very earnestly desire the continuous withdrawal of the Government from vessel ownership and operation until the government-owned fleet is entirely disposed of by sale or scrapping at the earliest practicable date. This is a first essential of the firm development of our merchant marine."*—Eugene E. O'Donnell.

In the La Follette seamen's law are presented not a few difficult problems. This act was passed with the assumption that it would provide freedom—so-called—for seamen. The practical result, however, has been the lessening of discipline on American ships as reported by ships' officers and United States consular agents.

Our steamboat inspection laws and rules and other navigation laws and regulations were made the object of a very careful study more than two years ago by a committee of maritime men established by authority of the Shipping Board—a committee of which Mr. P. A. S. Franklin was the chairman. Mr. Alfred Gilbert Smith was chairman of the sub-committee on construction and inspection, and Mr. J. Parker Kirlin was chairman of the sub-committee on personnel and legal adviser to the committee.

As is known to most of us, that committee completed its deliberations and presented its report to the Shipping Board two years ago, and the legal division of the Shipping Board is now engaged in recodifying and consolidating the navigation laws in accordance with the committee's report. I can do no better by way of indicating what ought to be done to cure the unjust or obsolete features of our maritime laws and rules than by summarizing the recommendations of this committee as this report was recently released to the press by the United States Shipping Board.

Summary of Report of Navigation Laws Committee

It was found that our navigation laws are scattered through a large number of volumes of statutes and regulations passed at different times, and in many cases amendments have been enacted with clauses repealing acts and parts of acts inconsistent therewith, making a comparative study of the various statutes and regulations necessary in order to determine just what the law or regulation is on any particular subject. It was found also that authority to make regulations which were to have the force of law and the responsibility for enforcing the laws were scattered among a number of boards and bureaus in different departments of the Government. The committee considered that next in importance to the recodification of the law was the consolidation of responsibility for enforcement in a single department.

Steamboat Inspection Laws.—The committee found that much of the criticism directed at the Steamboat Inspection Service was due to the mandatory character of the laws under which this service operates and the fact that no discretion is left to the officers responsible for the enforcement of the law.

An example is that of the annual hydrostatic test of marine boilers, using cold water, of one and one-half times the working steam pressure allowed. Practical engineers claim that it is unwise annually to subject marine boilers to a stress the result of which makes doubtful the value of the application of this hydrostatic pressure at such frequent intervals.

A further requirement of the inspection laws is the annual inspection of the hulls of cargo vessels. At these inspections it is required that all cargo be discharged and the boilers emptied in order that the inspection may be made. This means a loss of from twenty-four hours to two or three days, depending upon the size of the vessel.

It is suggested that passenger vessels might very well be subjected to these annual inspections, with the exception of the hydrostatic boiler test, and that the life-saving equipment of all vessels should be annually inspected. The inspection of the hulls of cargo vessels might properly be made at the survey periods, once in three or four years.

It is particularly desirable also that American vessels trading between ports in foreign countries should not be obliged to return to an American port for the periodical inspections required by law and regulations made pursuant thereto. These inspections might well be carried out by representatives of the American Bureau of Shipping located in various foreign ports.

Seamen's Act.—It is the general belief that the repeal of the Seamen's Act will place American shipping on an equality with foreign vessels. This is not the fact, however. What the Seamen's Act really does is to place added burdens upon the American ship which are not applied to foreign vessels, and, while it should be materially modified, there are certain humane features which should remain undisturbed. Those features, which have met with the greatest opposition from shipowners and which have caused the greatest hardships are the language tests, able seamen requirements, the excessive requirement of lifeboat men and the frequent payment of wages to seamen in foreign ports.

Section 14 of the Act, which relates to life-saving equipment, was taken from the regulations of the International Conference on Safety of Life at Sea. These regulations were intended primarily to apply to passenger vessels engaged in trans-oceanic trade. The application of these stringent requirements to our small coastwise and inland vessels has reduced their passenger allowances, ultimately forcing several of these companies to suspend operation.

It has been earnestly recommended by the Shipping Board Committee that Section 13 of the Seamen's Act be so amended that the extreme requirement of three years' apprenticeship for a rating as able seaman be reduced to a reasonable period so that this manifest discrimination against young Americans may be eliminated.

Continuous Discharge Book.—Another important recommendation of the committee affecting the seamen's law and the sea going personnel was one in favor of the introduction into the American service of the Continuous Discharge Book, with its record of the conduct and efficiency of seamen. It has long been in use in the British and other foreign services. This book has already been given out by the Pacific American Steamship Association with marked success and will be utilized also by the American Steamship Owners' Association.

Until the government-owned fleet can be disposed of there can be no objection to the maintenance by the Shipping Board of essential ocean services non-competitive with private enterprise. But this situation must be handled very carefully so that private plans may not be blocked. Every effort ought to be made by the Shipping Board to turn every one of the essential services over to private ownership and management at the earliest possible moment. Many operators dread more than foreign competition even the faintest risk of the competition of their government.

> *"Either this present bill must be promptly enacted, or the United States in defiance of sound business, and in defiance also of the instinct and conviction of the vast majority of its own citizens, will be committed to a policy of government ownership and operation in the shipping business, and worse than that, to a policy of governmental subsidized competition with American private capital and enterprise. Such an unjust policy as this would not be tolerated for a moment by manufacturers. It would not be tolerated by agriculture. It should not be imposed on the merchant marine."*—H. H. Raymond, President American Steamship Owners' Association.

Prompt Passage of Shipping Bill Demanded

Let me emphasize the truth which all practical men of our industry realize, that the government-owned fleet can never be sold until ample national aid is provided for the operation of those ships after they have passed into the hands of those who have the knowledge and the means to use them. Absolutely vital to the success of the American shipowning and operating industry is the prompt passage of the great Shipping Bill proposed by President Harding. If that fails, everything is lost that has been done toward a permanent restoration of American shipping in the overseas trade. If that fails, the American people lose all hope of realizing anything on their $3,000,000,000 investment in the shipping business. The national importance of this measure cannot be overestimated. Our foreign competitors are anxiously watching the result of the present legislative effort in Washington. They know as well as we know that this bill, once enacted, will make America a great commercial power on the seas. They dread the result of national aid applied to shipping exactly as it has been so successfully applied in the past to manufacturing, mining, farming and other protected industries in America.

What the Shipping Bill Will Do

The pending shipping measure offers substantial aid to every branch of our merchant marine. It proposes that 50 percent of the immigration into this country be reserved to American ships. This of itself will be a most powerful help to the regular mail, passenger and cargo lines of transatlantic steamers. Another feature of the bill is the deduction from income taxes of shippers of 5 percent of the freight money on goods exported or imported in American vessels. Though this will not directly benefit the shipowners, it will offer a strong inducement to shippers inward and outward to prefer the American flag and will thus assist to give American ships the full cargoes so necessary to profitable operation. Exemption of net earnings of American ships in the foreign trade from Federal taxation, if the amount of the exemption is pledged to the building or purchase of new ships, will encourage shipbuilding and increase the active merchant marine. The construction loan fund of $125,000,000, while costing the Government nothing in the long run, will promote the building of new tonnage of superior character.

Very important is the provision in the new bill that will make it possible to secure more liberal allowance for depreciation for shipping, thus placing us more nearly on an equality in capital costs with our competitors. President Harding's policy of prompt diversion of the army and navy transport services to the merchant marine is made possible in the new legislation. An extension of the coastwise law to the Philippines is certain to have the same beneficial effect on shipping and trade as the extension of the coastwise law to Porto Rico and Hawaii.

What shipowners and operators are probably thinking most of, because they can measure its advantage in dollars and cents, is the direct aid of the new bill in the form of compensation or encouragement to both cargo ships and mail ships. This is the feature of the new proposal that is most actively discussed. It is the part of the bill that must meet the sharpest opposition. But let nobody imagine that this direct compensation was put into the bill to be pulled out again. Without the direct aid of the proposed compensations or subsidies, the great effort of the nation to solve its shipping problem cannot and will not succeed. The indirect aids are themselves inadequate. If the nation is going to help its shipping it must help it effectively and not place it half-way on an equality with its overseas antagonists. Nothing less than complete action will suffice.

We recognize frankly that, though we need all this entire measure of government help and can do nothing of ourselves without it, nevertheless we cannot lean on government aid alone. Given all these improved conditions, the problem of the American merchant marine must, after all, be actually worked out by American shipowners, operators and builders through their own exertions. We must win our own success, achieve our own destiny. We must be quick to distinguish and adopt the newest and best ideas of ship design and construction. We must operate our ships with the utmost possible enterprise and economy.

Fleet Corporation Salaries to Be Reduced.—The House of Representatives has finally prevailed that the appropriation bill providing funds for the Shipping Board for the fiscal year ending June 30, 1923, shall provide for a reduction of the salaries paid to vice-presidents of the Fleet Corporation. The Senate conferees on May 9 finally agreed to a compromise which allows 6 salaries at not to exceed $25,000 each, and 2 at not to exceed $20,000 each.

Developments In Marine Insurance

What Is "Ordinary Course of Transit"—Barge Canal Coverage—Syndicate and Salvage Operations

By "Bordereaux"

ONE of the eternal questions in the marine insurance market is what is the meaning of "ordinary course of transit" in the warehouse to warehouse clause. The assured finds it difficult to understand how there can be any break in an insurance that covers from the warehouse of the shipper to that of the consignee, even though goods are temporarily placed in warehouse en route. The question has assumed vital interest of late in view of the possible changes in the tariff which have caused some importers to stop their goods at a foreign point awaiting a definite settlement of the tariff controversy. Many importers of Egyptian cotton are, for this reason, ordering their cotton held in Liverpool, and that means storing the shipment and interrupting its transit.

It should be understood by the assured that the moment the transit is broken, not only does the insurance terminate but it does not automatically reattach when the goods are again put in transit; it is treated under marine policies as a new risk. However, if an assured's policy covered both from Egypt and Great Britain, the insurance from Liverpool would attach as a new shipment at the time of the cotton leaving the warehouse for destination.

Numerous phases of this question arise with regard to goods which arrive in the United States and are temporarily stored awaiting distribution. Thus many tea importers who bring teas via the Pacific Coast place them in storage in Coast warehouses for a short time before distributing them throughout the United States. Even though the policies of such importers cover to any point in the United States, the insurance is terminated by the warehousing of the teas and does not reattach on their subsequent reshipment. However, as above indicated, if there were a clause in the policy covering from one point in the United States to another the assured would be covered on reshipment. Many policies contain a specific clause in cases of this kind either covering while in warehouses en route or else providing for the reattachment of the insurance on reshipment.

Still another prolific cause of misunderstanding along this same line arises in connection with goods being placed in bonded warehouses at this port. Many importers are apparently under the impression that, if held but temporarily in bonded warehouses, the policy continues in force, while others with specific insurance for their bonded goods expect the goods to be insured when finally taken from the bonded warehouse to the warehouse of the consignee.

Although the matter of storage and transit warehouses is confusing to the layman, yet the distinction is clear cut, customs and appraisers stores being included in transit sheds while general order, bonded warehouses and other stores used for storage purposes are not considered as transit warehouses. Goods are still in ordinary course of transit while in the former sheds.

Barge Canal Coverage

IT was doubtless gratifying to friends of the New York State Barge Canal to learn that on the official opening date no less than ten fleets awaited the word to sail, and fifteen more got away within a week after. Port Superintendent John S. Gaynor predicts a record season. In boosting the canal, Governor Miller calls attention to New York's unselfish attitude in not charging tolls for the use of this waterway. Up to 1880, when the toll charges were abandoned, $135,000,000 had been collected by New York State through the revenue from this source. Instead of charging for its use, New York has spent $154,000,000, since 1903, in its improvement and enlargement.

Last season many complaints were heard about the failure of the shipping public to take advantage of the facilities offered by the canal for handling both through and local freight. Shippers claim that they dislike being compelled to shift during the winter months to the railroads, with the various changes thus made necessary in their methods of routing shipments, and the slight saving in freight, they insist, is not sufficient inducement to overcome the disadvantages of canal traffic. Many shippers state that the canal insurance charges offset the freight savings; but the underwriters who insure canal barges and cargoes claim that there is no ground for a reduction in rates, as last year did not show a profit, mainly due to numerous strandings in the narrow portions of the waterway.

Registered Mail Losses

THE recent registered mail bond robbery, by which the Chase National Bank is reported to have lost half a million dollars, again directs attention to the hazardous character of insuring bearer bonds. Within the past year far too many marine insurance offices have been hard hit by losses from this source, and several have altogether discontinued writing this kind of business. The rates are so small and the values involved are so large that one loss is likely to wipe out several years' premiums. It is quite possible, indeed, that one heavy loss would make recoupment out of the question. In the robbery above referred to there appears to be some doubt as to whether the transit underwriters' risk had attached, because the policies provide that the risk under the transit policy does not attach until the packages have been mailed. Prior to that time the risk is on the sender or his surety underwriters.

Cotton Flood Risks

MARINE underwriters are considerably disturbed by the recent frequency of damage to cotton by floods in the South. The Trinity River flood at Waxahachie, Texas, washed away more than one hundred bales and damaged eleven hundred more. Of this number it is estimated that fully four hundred bales were covered for flood risk by marine insurance. Under open cotton contracts the flood risk is regularly covered, the charge for such hazard being ten cents, and it is included in the basis rate. Cotton stored in warehouses at the port while under marine policies is subject to additional premium for the flood risk, if such warehouses are less than eleven feet above mean low water.

Lake Self-Dischargers

IT is frequently asked lake cargo insurers what difference in rates is likely to develop in view of the impressive improvements in lake cargo carriers and the facilities for handling shipments. There is, for example, a new type of vessel on the lakes that is known as a self-discharger which

is to be used in carrying ore and other heavy bulk cargoes. This craft will lessen the present time of discharge; and that is saying considerable in view of the fact that a vessel is already able to unload twelve thousand tons of ore and to load an equal amount of coal and sail from port on her return trip the same day she arrives. Oddly enough, the effect of these improvements on underwriting should be to increase the hull rates; the logic being that the less time taken in ports means the more time spent in navigation, with a consequent increase in hazards.

East Coast-West Coast Service

INTERESTING underwriting phases have come to the fore in connection with the first round-trip between New York and the West Coast recently scored by a steamer of the Pacific Mail line. This service can boast of several fine modern vessels especially attractive for passenger carriage and light shipments. The point that interests the underwriters is the numerous stops made, especially on the West Coast of Central America. These interruptions to the voyages are of more interest to passengers and shippers than to insurance men. Such bits of navigation, particularly on the part of large steamers, add considerably to the risk because of the increased hazards of collisions and strandings.

Competition in Repairs

THE well authenticated report is that no less than eight shipyards submitted bids on the steamer *Granite State,* and that the successful bidder got the job at a figure $40,000 lower than its nearest competitor. The hull underwriter views this active competition in repair work with unmixed satisfaction. To him it means a marked saving in both particular average and general average repair costs.

Pacific Coast Rates and Conditions

ON the Pacific Coast rates continue to be uniformly low in the marine insurance market. There has been little stimulus given to a stiffening of the tariff, but there are no results as yet to encourage the underwriters. Conditions are, however, looking up, in that they are slightly more stringent. It is becoming increasingly difficult there for brokers to cover merchandise written with "fancy" conditions. For example, it was recently found impossible to cover in the San Francisco market the risk of leakage of linseed oil in barrels. Eighteen months ago such an offer would not have gotten past the first office to which it was submitted. This indicates a slow but significant return to the normal basis. The theft and pilferage situation has greatly improved of late on the West Coast, although the underwriters are uncomfortably uncertain as to whether this is the result of a betterment of the public moral fiber, or merely because goods simply can not be sold, even by the thieves themselves.

Marine Syndicate Conditions

IN an official summary of its recent annual reports the management of the American Marine Insurance Syndicates makes the statement that from organization, August 10, 1920, to December 15, 1921, Syndicate "B" received total earned premiums in the sum of $679,588.35, and received interest amounting to $8,881.02. Its total payments for losses, commissions and net expenses amounted to $211,402.63. The credit balance, therefore, was $477,066.74 for that period. Syndicate "C" wrote premiums of $8,372,388.96, of which the total of earned premium is $4,207,741.47. To this should be added interest amounting to $32,989.99. The total of payments for losses, commissions, net expenses, premium tax and expense reserve was $2,989,134.11; making the credit balance $1,251,597.35. There has been practically no activity in Syndicate "B" for almost a year, due to the inability of the Shipping Board to sell its vessels.

It is important to note that the Syndicates' management has met the repeated request of the Shipping Board for relief in the schedule rates, which had been determined upon vessels sold by the Board, so as more nearly to represent the cost of insurance in the world's markets. A general reduction in rates was felt to be impossible, in view of the demoralized condition of the marine insurance markets of the world and that business is being done in foreign markets at rates considerably below what has been current for some years, although the weight of evidence is that the hull business for those years was done at a loss. However, a plan has been formulated to help meet the Board's predicament, which briefly is as follows:

1. Where a private owner's interest is written in "C," the same rates will be quoted in "B" for the Government's interest.

2. Where a private owner's interest is placed with underwriters other than "C," Syndicate "B" will quote for the Government's interest the same rates as would have been quoted for the owner's interest, if insured with Syndicate "C."

All obligations to place such insurance with "B" are suspended and the Government and owners are at liberty to place the insurance in the world market, if so decided in each case by the Shipping Board.

Salvage Association Results

IN a summary of the minutes of the annual meeting of the United States Salvage Association, Inc., Acting Manager Lawrence J. Brengle states that the major part of the work of organization has been in the foreign field. Up to March 1, 1922, the Association had appointed agents at 88 ports. "South and Central America and the West Indies are practically completed," said he, "and our representatives in the United Kingdom, France, Spain, Portugal, Norway and Sweden are likewise established at practically all the important ports. Our main efforts at present are directed at finding suitable agents in Germany, the Levant, Africa, Asia and in the East Indies."

Foreign agents have handled nearly 50 damage cases for the Association. Since beginning business on November 1, 1921, a total of 3,049 damage surveys were handled by the Association's branch offices and agencies in the United States, up to February 1, 1922. Included in this total were 786 damage surveys for private account, and 2,263 for the United States Shipping Board. New York produced the greatest amount of work, having made 1,194 surveys; New Orleans, 441; Norfolk, 321; Baltimore, 217; Galveston, 201; Boston, 159; Savannah, 152; Seattle, 61; and San Francisco, 47. There are now 435 Shipping Board vessels in commission, and on these vessels alone the Association's surveyors are making an average of 150 damage surveys and 100 condition surveys per month.

Masters' Insurance Opposed

A VENTURESOME British insurance company plans to issue a form of unemployment insurance for ship masters when disqualified for service because of an accident, but the proposal is meeting with little support in this country. Our underwriters see in the proposition an avenue for an increase in moral hazards as respects ocean hull and cargo insurance. Guaranteed that their actions are protected by insurance against personal financial loss, unscrupulous masters might easily detect in this device a way to comfortable retirement through the means of a fortunate "accident" at sea.

White Star Liner Majestic, the Largest Vessel in the World

The New White Star Liner Majestic

World's Largest Steamship Enters Transatlantic Express Passenger Service — Details of Hull and Machinery

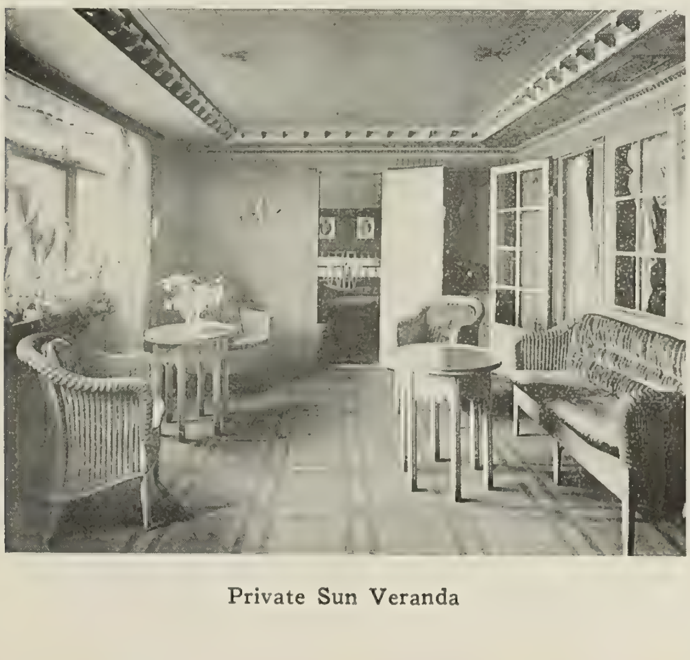
ANOTHER step in the development of the transatlantic liner has been reached by the completion of the *Majestic* of the White Star Line, which arrived in New York on her maiden voyage on May 16. Although falling short of the 1,000-foot liner so often dreamed of and discussed in marine circles in recent years, nevertheless the *Majestic* with her overall length of 956 feet and her gross tonnage of 56,000 surpasses in size any other vessel afloat and with her conversion, before completion, from a coal burning to an oil burning vessel she bids fair to be classed as one of the speediest vessels in the North Atlantic service.

Designed originally for the Hamburg-American Line, the *Majestic* was built in Germany at the yards of Blohm and Voss in Hamburg and, when launched in 1914, was christened the *Bismarck*. With the outbreak of war the construction of the vessel was suspended, but after the armistice was signed she was purchased from the Reparations Committee by her present owners.

The principal dimensions of the *Majestic* are as follows:

Length overall	956 feet
Length between perpendiculars	912 feet
Beam	100 feet
Depth, molded	57.1 feet
Gross tonnage	56,000
Horsepower, designed	66,000
Speed, designed	23½ knots
Number of passengers	4,100

With accomodations for 4,100 passengers, the *Majestic* has nine decks, five of which run the full length of the ship, four being in the superstructure. These four superstructure decks occupy about a third of the ship's length and contain



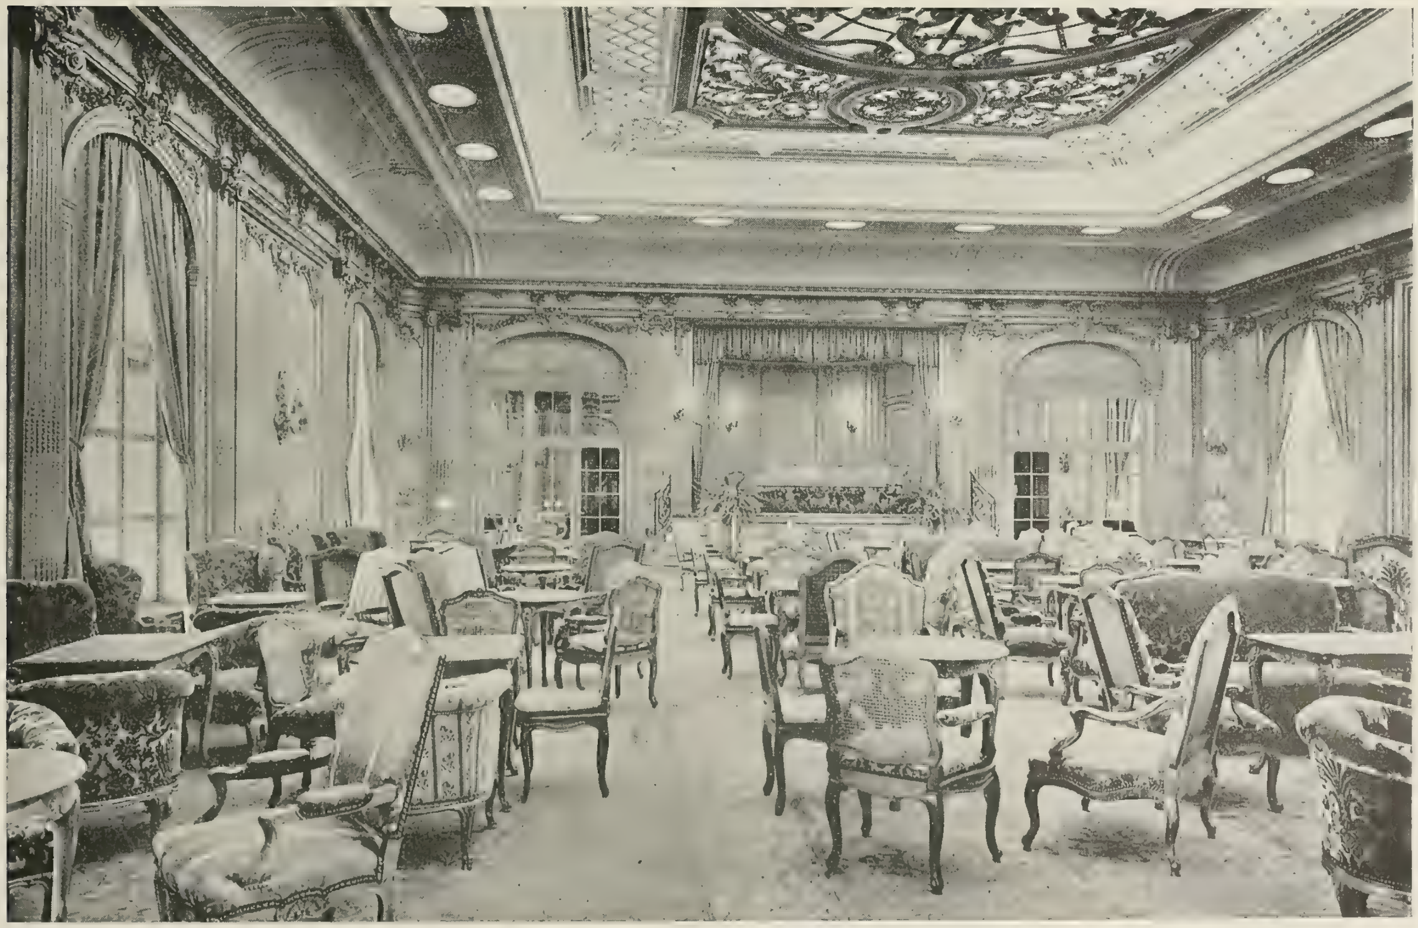
Private Sun Veranda

Swimming Pool

Palm Court, Adjoining the a la carte Restaurant

Main Dining Room

Grand Foyer



The Lounge, the Largest of the Majestic's Public Rooms

cabins and public rooms. Seven of the decks are devoted entirely to the accommodation of passengers. Because of the fact that the stacks are divided below decks and brought up the sides of the vessel it has been possible to provide a broad central foyer through the upper decks, unlike that on any other ship now in commission. Electric elevators and broad starcases of easy pitch connecting all decks are intended to minimize fatigue to the passengers.

Luxurious Public Rooms

On the promenade deck are the main first class public rooms, which, in proportions and elegance, are in keeping with the size and dignity of the ship. The principal rooms occupy a continuous steel deck house two stories high.

From the central foyer on *B* deck entrance is obtained on the one hand to the lounge and on the other to a spacious palm court leading to the a la carte restaurant. Here again advantage is taken of the fact that the boiler casings are divided to provide a clear space of 250 feet extending through these rooms. Forward of the lounge is a reading and writing room and above that the smoking room. The main first cabin dining saloon is on *F* deck with the central part extending to *E* deck, the ceiling being 31 feet high, the loftiest on any ship afloat. The dining room is 98 feet by 117 feet and seats 652 persons. The a la carte restaurant accommodates 200 more.

The lounge is 54 feet by 76 feet; its ceiling is 26 feet high. This room is distinguished by its perfect symmetry, unbroken by bays, projections or roof supports, by the beauty of its oak paneled walls and by the tall French windows. At one end of the lounge there is a concert stage and a large dancing floor which is in use nightly.

Possibly the most striking single feature of the *Majestic's* interior is the Pompeian swimming bath which is decorated with rich marbles and brilliant mosaics. The tiled pool has an area of 820 square feet and a depth of from 4 feet to 9 feet.

Stateroom Accommodations

The *Majestic* has a passenger capacity of 4,100 and for their accommodation 1,245 staterooms are provided of which 472 are in the first class. Many of the first class rooms are in suites that approach in size and equal in luxury the finest apartments ashore. The two largest suites include 8 rooms each with 3 baths.

The *Majestic* is fitted with all the latest accessories and comforts for passengers of all classes. Both steam and electricity are employed for heating the public rooms and staterooms. The ventilation system automatically assures a constant supply of fresh air at the proper temperature to all parts of the ship.

Each class of passengers on the *Majestic* has its own galley, pantry, culinary and service staff. There are no less than eight galleys on the ship.

The second and third cabin accommodations are unusually fine. The second cabin dining saloon, seating 400, has direct communication by electric elevator to the second cabin lounge, reading rooms and foyer. The third class also has a lounge, smoking room and dining saloon and many airy well-lighted two, three and four-berth staterooms.

Propelling Machinery

Through the courtesy of Joseph Wolff, chief engineer of the *Majestic,* we are enabled to present the following notes on the main features of the vessel's propelling machinery:

Propulsion is by four screws driven by Parsons reaction type turbines. There are four sets of ahead turbines and four of reversing turbines. Both ahead and astern turbines are connected to the same shaft in each set. The engines are rated by the builders as capable of developing 66,000 shaft horsepower at 180 revolutions per minute but on the ship's trial trip in the North Sea in April it was found that they developed about 80,000 shaft horsepower at this speed. The astern turbines developed 36,000 shaft horsepower. The steam pressure on the trials was 16 atmospheres or 240 pounds per square inch gage.

The ahead turbines work in series when the vessel is at full speed, the steam passing from the high pressure turbine on the port inboard shaft to the intermediate pressure turbine driving the starboard inboard shaft and thence to the low pressure turbines each driving an outboard shaft. The astern turbines also work in series, the high pressure in each case being on the inboard shaft and the low pressure on an outboard shaft.

The weight of the turbines with their shafts is 3,400 tons. The shafts are 16½ inches diameter. The propellers are four-bladed each with a diameter of 16 feet 6 inches and a pitch of 14 feet 11.5 inches.

Steam is supplied by 48 oil burning Yarrow type watertube boilers, having a total heating surface of 220,000 square feet. The boilers work under forced draft and are fitted with Mumford automatic feed regulators. The fuel oil is burned through the White low pressure system. In all, there are 240 oil burners or five to each boiler. Owing to the character of the system employed, the temperature in the firerooms is no higher than that in the engine rooms. One fireroom attendant has charge of three boilers or fifteen burners. With three watches in 24 hours, only 48 attendants are required to man the fires. There are also employed in the firerooms, however, 36 cleaners, making a total fireroom staff of 84 men as against a staff of 377 which would have been required had the ship burned coal. The latter number would have been represented by 12 chief stokers, 197 firemen and 168 coal passers.

The engine room force on the *Majestic* comprises 70 engineers of all classes, 42 oilers and 4 storekeepers. The engineers include the chief, a staff chief engineer who stands next to the chief in authority, a senior, intermediate and junior with their assistants in each of the three grades, namely: second, third and fourth, besides three electrical, three deck, three sanitary, three hydraulic, one Diesel and others specializing in refrigeration.

The fuel consumption on the *Majestic* has not yet been accurately determined but on the Atlantic passage it will approximate about 800 tons of oil a day at ordinary service speed. Should the vessel be driven to her capacity, the consumption would rise somewhat disproportionately for the added speed secured above her normal rate, which is expected to be about 25 knots. With an oil bunker capacity of 8,200 tons, the *Majestic* will carry nearly enough oil on one filling to make the round voyage between Southampton and New York.

The weight of the complete main engine and boiler plant totals 8,500 tons.

Auxiliary Machinery

The *Majestic's* auxiliary equipment is unusually large and diversified and includes a Diesel engine-driven 90-kilowatt generator installed 19 feet above the bulkhead deck for supplying current not only for 800 emergency lights distributed all over the ship but also for lowering the lifeboats and for the navigating, signalling and emergency wireless equipment.

The main electrical plant consists of five turbo generator sets, each of which develops 288 kilowatts at 115 volts at 2,000 revolutions per minute. Current from the main switchboard is distributed by 32 feed cables, 22 of which are for power purposes, 6 for lighting and 4 for heating. In all, there are 225 electric motors on the ship with a collective capacity of 1,565 horsepower.

Special attention has been given to the heating and ventilating and refrigerating equipment on board. Steam-driven CO_2 refrigerating machinery is installed for the provision storerooms while an electrically-driven refrigerating installation is provided for the refrigerated cargo in the forward part of the vessel.

Combined Passenger and Cargo Liner Conte Rosso

New Italian Liner Conte Rosso

Passenger Vessel Built in England for Lloyd Sabaudo Has Unusually Luxurious Appointments

THE new Italian liner *Conte Rosso* which has recently been completed in the shipbuilding plant of William Beardmore & Company, Ltd., at Dalmuir, Scotland, will shortly take her place in the service of Lloyd Sabaudo Company of Genoa, Italy, which will employ her in its passenger and cargo service between Italy, South America and North America.

The vessel is of the shelter deck type without tonnage openings and was built under special survey to the highest class of Lloyd's Register, the British Corporation and the Register Navale Italiano. The requirements of the International Convention for the Safety of Life at Sea have also been complied with and due consideration given the design of the vessel in order to build it in accordance with the latest regulations of the Italian and American immigration laws.

Designed with a straight stem well raked forward, an elliptical stern with the lower portion bossed out to provide a space for the steering gear, two funnels and two pole masts, the vessel has an exceedingly trim appearance that pleases the eye and conforms to the standards of a well designed ship.

Twin screws are used to drive the vessel in service at a speed of 18½ knots and the main propelling units of geared turbines will develop approximately 17,000 horsepower at this speed.

Decorations

The outstanding feature of this remarkable new vessel is the comfort, convenience and elegance contained in the public rooms and passenger accommodations. The result attained in these quarters represents a marked advance in the appointments provided on passenger ships and will no doubt establish a new precedent in the decoration and arrangement of these spaces on future vessels.

In conformance with the expressed desire of the owners to incorporate in the decorative scheme their experience of the requirements of the Italian and South American service, the whole of the decoration of the first class public rooms was entrusted to the firm of Messrs. Coppede of Florence. These rooms are decorated in a most beautiful and artistic manner that will satisfy the most fastidious. The discriminating traveler will be assured of delightful surroundings during the voyage.

The main entrance hall is in the style of the Italian Renaissance in oak and mahogany. Hand carvings, inlaid work, tapestry and stained glass all play a part in the general scheme.

In the library, the style follows that of the Tuscan Renaissance, the woodwork being polished walnut finely carved and inlaid. A frieze runs around the sides and embodied in the general scheme are some 50 sea and landscape paintings. In lieu of the usual ceiling lamps four wrought iron electric standards with six lights each are located on the deck and each reading and writing table is provided with an individual lamp.

A music room is provided which is arranged and decorated in Pompeian style.

The dining rooms are arranged on two decks, the upper

providing seating accommodations for 72 persons arranged at tables for two, four and six. This room is decorated in the style of the Italian Renaissance and around the sides is a dado carved with tooled and gilt leather panels. Two large pictures of war episodes in the life of Conte Rosso recall the history of the man after whom the vessel is named. The lower dining saloon has seating accommodations for 176 passengers and the decorative scheme is similar to that in the upper dining saloon. One of the distinctive features of the lower dining saloon is a painting by Professor Cavalieri, one of Italy's foremost artists, representing the triumphal return of Conte Rosso to Nice in 1838.

The smoking room is decorated in the Moorish style of the Alcazar in Seville. Mahogany and chestnut are blended with very fine workmanship.

The veranda cafe is decorated in white maple in a modern style of simplicity which gives prominence to the fine grain of the wood.

Accommodations

Accommodation is provided for 208 first class passengers, 268 second class passengers, 1,890 immigrants and 442 officers and crew. An alternative arrangement of cabins is provided for, however, on the upper deck whereby the number of first class passengers can be reduced to 160 and the number of second class passengers increased to 364.

First class cabins are exceptionally large and include six cabins de luxe on the bridge deck, each of which is fitted with private bath and a constant supply of fresh hot and cold water. The woodwork in these cabins consists of framed and panelled mahogany and the furniture of polished African walnut including two large wooden beds, dressing table, writing table and chair, wardrobe and two easy chairs. Doors are fitted to adjoining cabins so arranged as to accommodate families en suite.

On the bridge deck amidships are provided forty-two single berth cabins. Twelve large special cabins for two persons each are arranged on the promenade deck and eleven similar cabins on the upper promenade deck. A feature of the first class staterooms is the fact that with the exception of those fitted for conversion to either first or second class they are provided with beds in each case, no upper berths being fitted. Another feature is that, wherever practicable, intercommunicating doors have been provided between the cabins and each cabin is supplied with a hot and cold fresh water service.

Second class passengers are carried in four-berth cabins, some of which are located on the upper deck, some on the shelter deck amidships and the remainder in the after portion of the bridge deck.

The second class dining room, which provides for a seating capacity of 254 persons, is located on the promenade deck aft and the smoking room for the second class passengers is on the same deck at the extreme after end.

Sleeping accommodations for immigrants are located on the upper and main decks, both forward and aft, and a dining room with a seating capacity of 450 is located on the shelter deck forward. Promenade space for immigrants is provided forward of the dining space and an open promenade above on the bridge deck.

Another of the new innovations incorporated in the design of this vessel is the location of the first and second class galleys on the boat deck. A special advantage of this arrangement is that the locating of the galleys above the level of the public rooms does away with the smell of cooking in the latter. Service hoists are provided which convey food from the galleys to the dining saloons.

The *Conte Rosso* is the newest type of combined passenger-cargo liner, which has found so much favor in recent years, to be launched. The owners have spared no expense in making this vessel one of the finest of its type afloat and there is no doubt but what their efforts will be well received by the passengers who travel the route over which the vessel plies.

Sternwheel Towboat for Mississippi River Service

Steel Western River Steamer to Be Used for Towing Oil Barges at New Orleans—Boilers to Be Oil Fired

THE Charles Ward Engineering Works, Charleston, W. Va., is constructing for service on the Mississippi River and the bayous in the vicinity of New Orleans a sternwheel towboat from designs prepared by Cox & Stevens, naval architects, New York, to the order of the Pan American Petroleum & Transport Company. The vessel, which will be used to tow oil barges from South Pass to points on the river and Bayou La Touche, has the following dimensions:

Length on deck	136 feet 5 3/16 inches
Length, overall	159 feet 8 13/16 inches
Beam, molded	32 feet 0 inches
Beam, overall	32 feet 8¾ inches
Depth, molded	5 feet 6 inches
Crown of deck	5 inches
Draft, mean, with 50 tons of fuel	48 inches

General Arrangement

The boat is equipped with all modern conveniences for efficient operation and the comfort of the crew, including modern plumbing, hot and cold water, steam heat, electric fans, door and window screens and social hall.

The hull and main deck house are of steel construction. Longitudinal strength is obtained by means of five longitudinal hull and two deck trusses. The deck trusses continue aft and form part of the long cylinder beams supporting the paddle wheel. Six transverse bulkheads divide the hull into seven compartments, one of which is utilized for a fuel oil tank.

The bow of the boat is of the modified scow form.

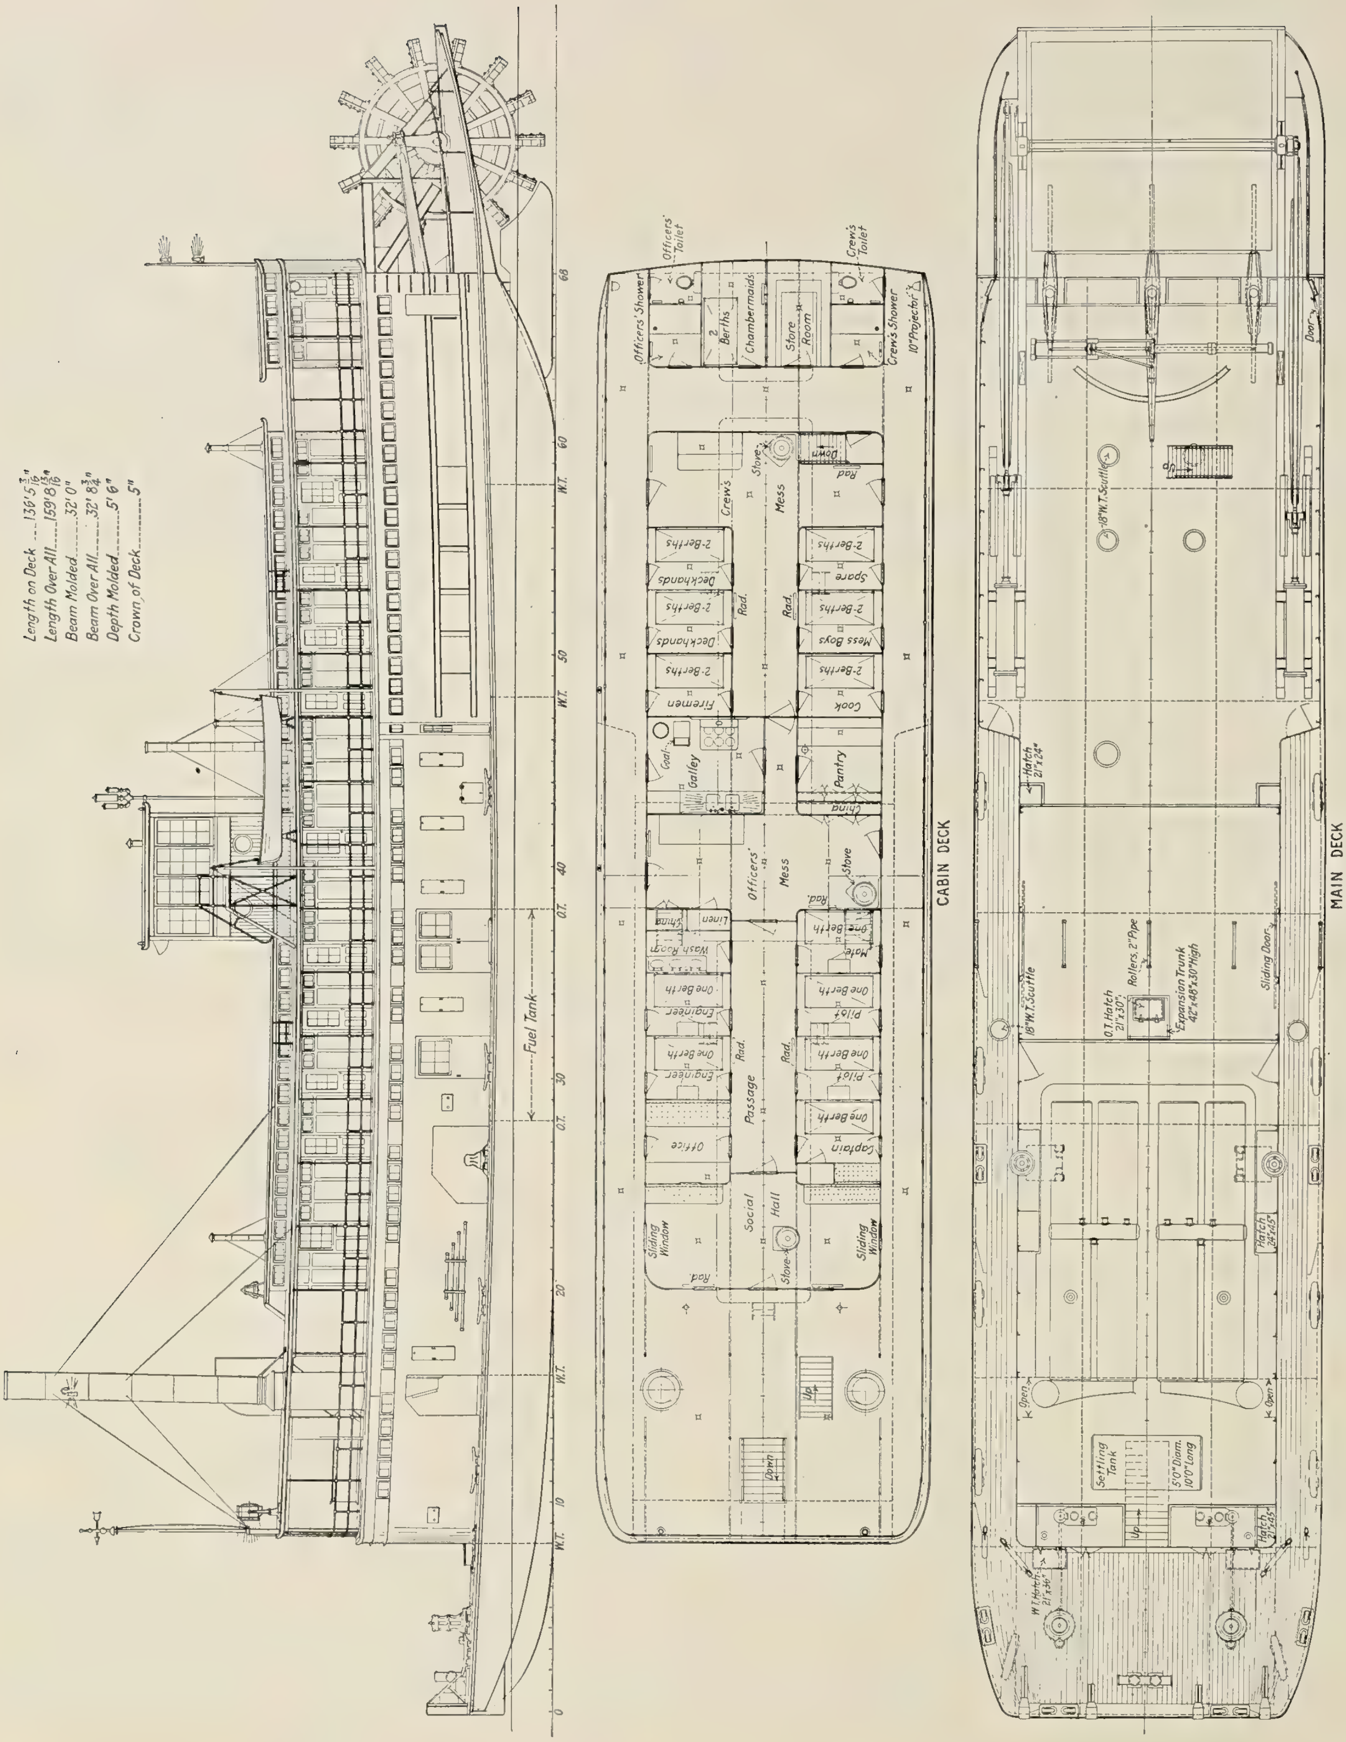
Propelling Machinery

The propelling machinery is of the high pressure non-condensing type with cylinders 18 inches in diameter by 7 feet stroke with balanced poppet valves and "California" cut-off gear as manufactured by the Charles Barnes Company of Cincinnati, O. The paddle wheel is 21 feet in diameter by 22 feet 6 inches long and has 14 buckets 36 inches in width.

Auxiliary Machinery

Two horizontal duplex plunger boiler feeders receive water from an open cold well connected to intakes located above the rounded bilge of the hull.

A duplex pressure coil heater is installed in the exhaust line common to both propelling engines. The surplus exhaust steam is carried to the stacks to increase the draft, or to the



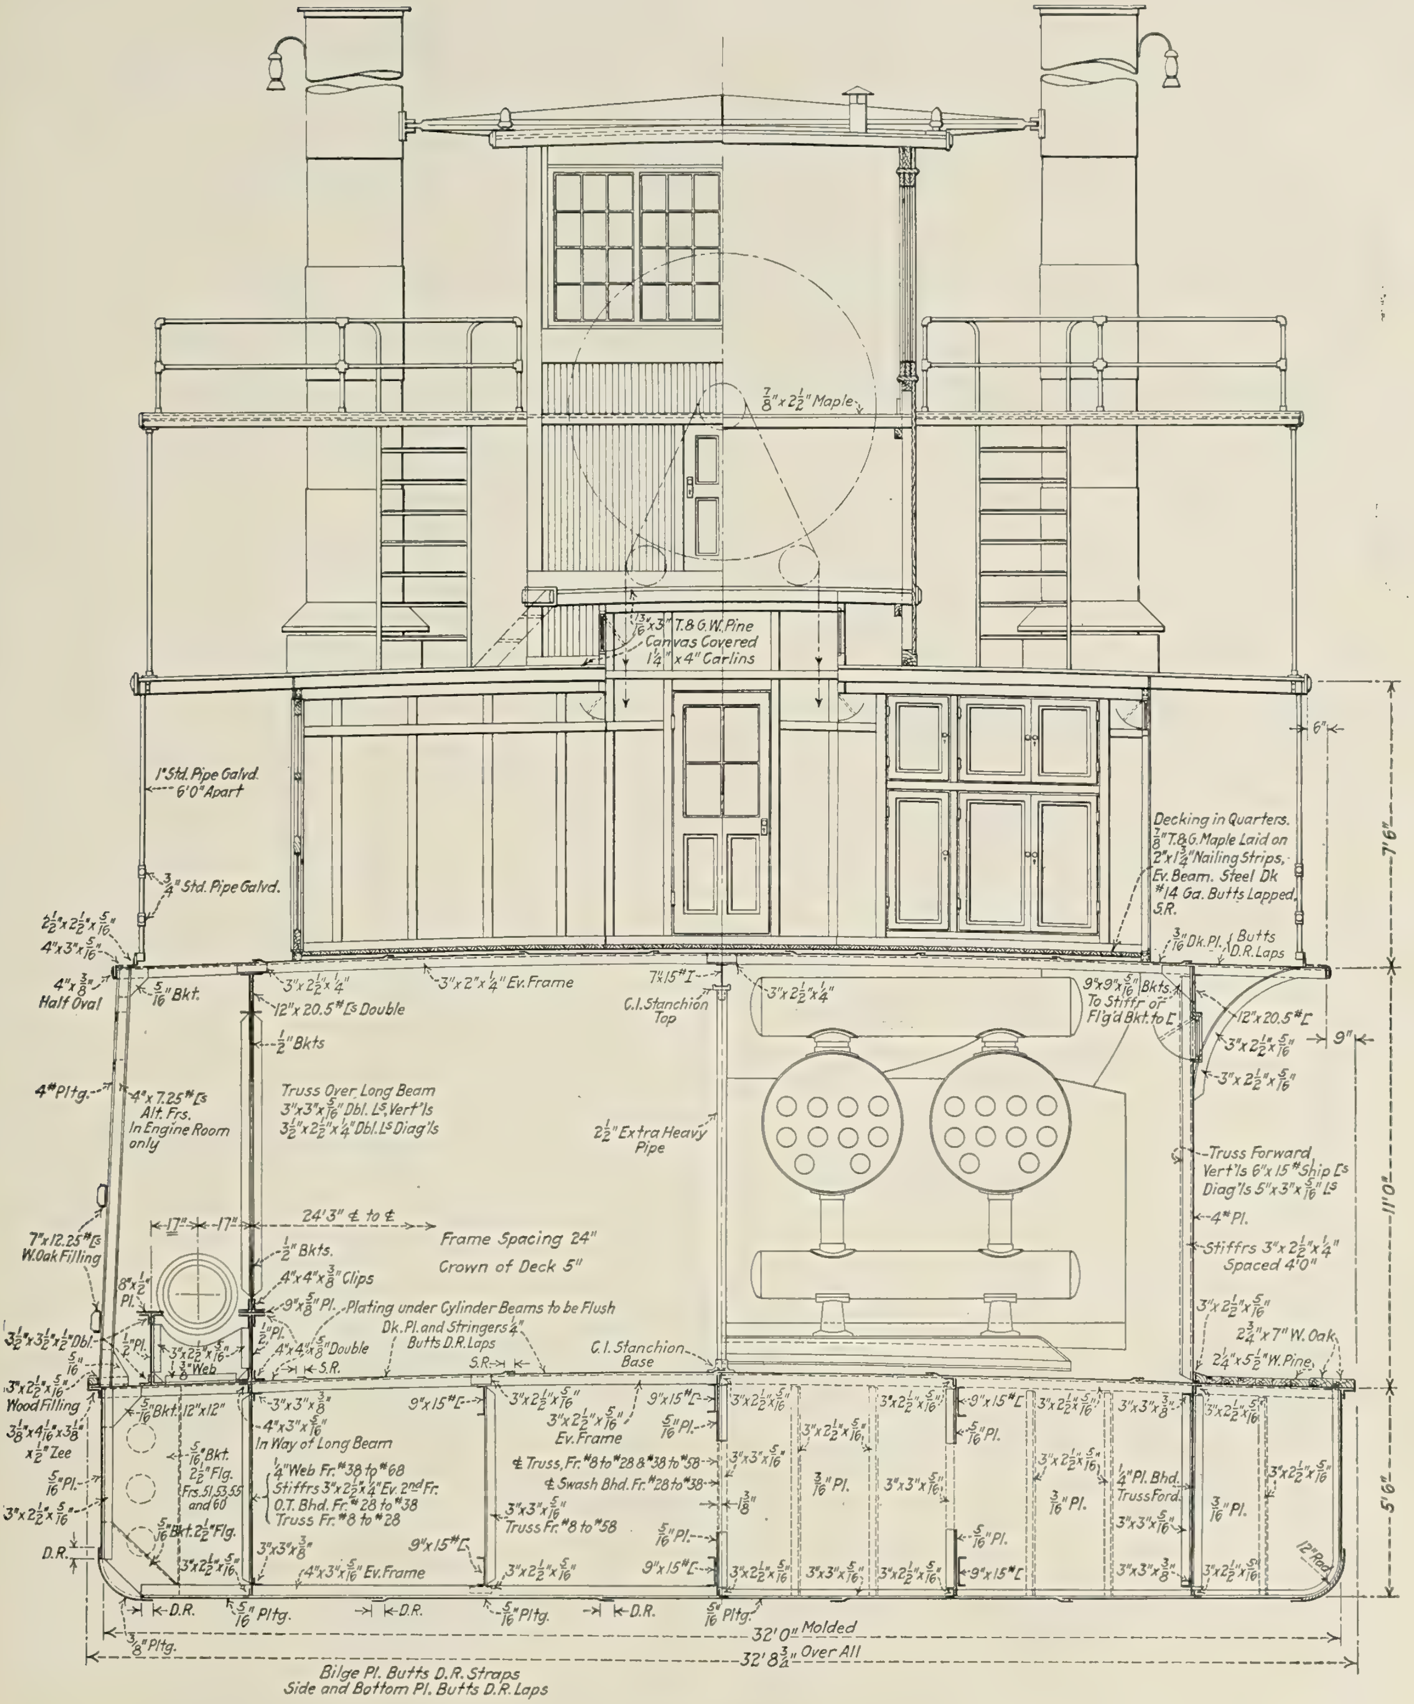
Profile and Deck Plans of New Mississippi River Shallow Draft Sternwheel Towboat

atmosphere, as desired. The boiler feed lines are installed inside the exhaust line to supplement the heating surface of the feed water heater.

A 15-kilowatt generator and sanitary pump complete the equipment. The hull compartments are unwatered by means of syphons.

The boilers are of the horizontal flue type arranged in two batteries with two boilers in each battery. They are 40 inches in diameter by 28 feet long with five 9-inch flues in each, designed for a steam pressure of 220 pounds per square inch. Oil is used for fuel.

Two double drum, double purchase capstans are located



Midship Section

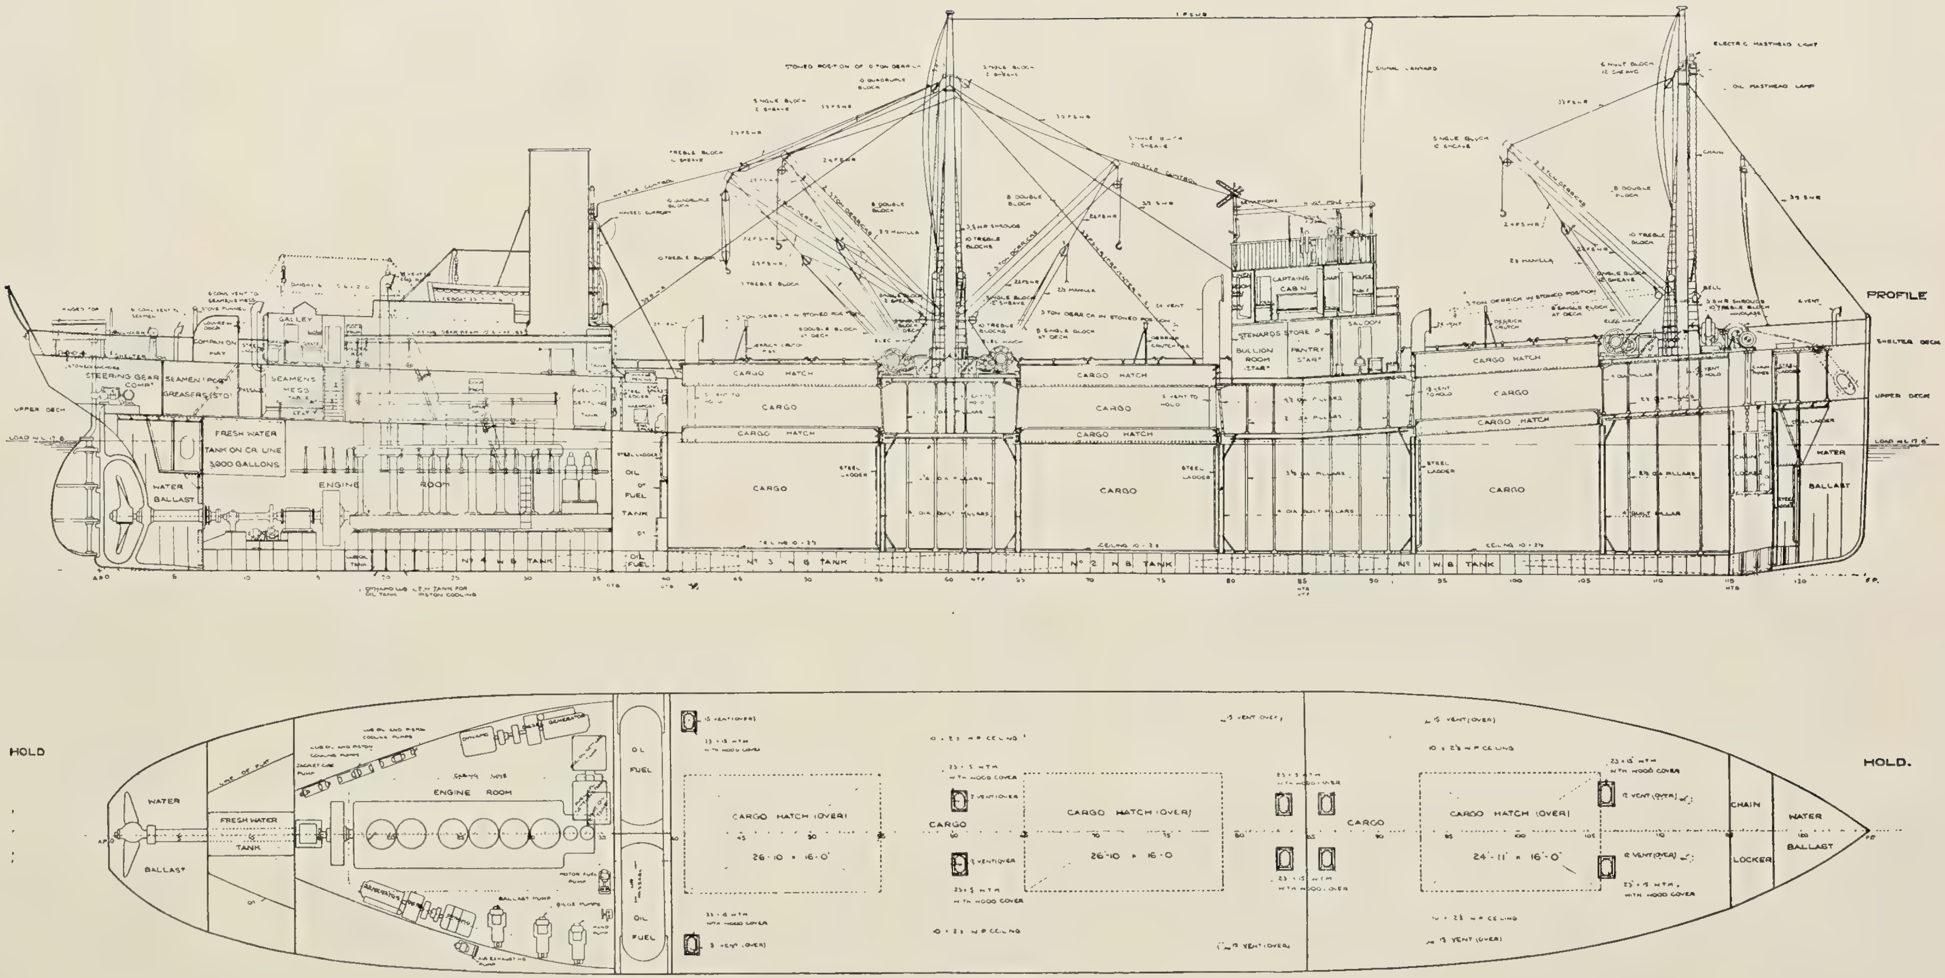
on the forecastle. Abreast the boilers are two side capstans having single drums, single purchase, operated by double reversing engines located below deck.

Three balanced rudders located in ports at the after transom are operated by a ram type steam steering gear installed under the boiler deck. The hand steering arrangement is attached to the inboard or long tiller arm with the tiller lines leading forward under deck and up to the 8-foot pilot wheel on the hurricane deck. Relieving tackle in addition to the above is included.

SERVICE

The boat will tow from one to four steel oil barges having

(*Continued on page* 400)



Figs. 1 and 2.—General Arrangement Plans of Single Screw Motorship Pinzon

Diesel Machinery for Single Screw Motorships*

General Problems Involved in Application of Single Motor to Vessels Over 2,000 Tons Deadweight—Details of Motorship Pinzon

By James Richardson, B.Sc.

NOTWITHSTANDING the vast increase in the number of ships fitted with internal combustion engines, single screw motorships of 2,000 tons deadweight and over have hitherto been exceptional. Increasing confidence in the Diesel engine as a reliable and satisfactory prime mover for marine propulsion, and the desire to take advantage of its economies in classes of vessels of low power, where the single screw arrangement is almost the only one permissible, have recently brought this subject into prominence. In discussing the general problems involved in the application of a single motor in ships of this size, as is the intention of the author in this paper, it may be helpful to give at the outset details of such a vessel.

Figs. 1 and 2 show the general arrangement and Table I gives the leading characteristics of the machinery and equipment of the single screw motorship *Pinzon*, built and engined by Messrs. William Beardmore & Company, Ltd., of Dalmuir. All deck and engine room auxiliaries are electrically driven. No boiler is fitted. The total consumption of fuel oil for all purposes in this ship at 9, 10 and 11 knots at sea, fully laden, in reasonably good weather is 3, 4 and 5.1 tons per day respectively, as given in Table II. The results of the machinery trials are shown by the curve in Fig. 3, and the main engine indicator diagrams are reproduced in Fig. 4.

In connection with the diagrams, attention may be directed to two points. Firstly, the very flat fuel consumption curve which lies below the 0.5 pound per brake horsepower per hour for the main engines, for speeds from a maximum of 125 revolutions per minute to 81 revolutions per minute, i.e., from over 1,400 brake horsepower to 420 brake horsepower. Secondly, an inspection of all the indicator cards shows from the toe of the diagram the very rapid release of the exhaust gases. The pressure drops to atmospheric almost before the bottom dead center is passed. This result is due to the large valve areas possible with the well-known Tosi arrangement of combined inlet and exhaust valves with the director valve controlling the exhaust gases and induction air. A further feature of this system is the extremely low exhaust temperatures, which never exceed 560 degrees F., although measured in the stream of the gases in the cylinder head.

Broadly stated, above 7,000 tons deadweight and 11 knots speed there is a good case for the retention of the standard twin screw arrangement of oil engines because of the lower total cost, the reduced weight of machinery, the shorter length of engine room, which compensates for the cargo space taken up by the extra shaft tunnel, and the reduced risks of breakdown. The personnel, however, is increased.

Problems Inherent to Single Screw Diesel Machinery

Turning in detail to the problems inherent to single screw Diesel machinery, it may be said first that the dictates of reliability and the limited man power available on board demand that certain operations shall be made possible and certain conditions fulfilled.

(1) The crankshaft shall be capable of being removed and replaced with the minimum dismantling of the main engine parts. As an alternative, the after length of the crankshaft, being the more liable to breakdown, shall be so accessible that it can be readily removed and replaced.

(2) That part of the fuel injection air service common to all the main engine cylinders should be in duplicate, including the blast bottle, so that failure of any pipe, joint, valve or chest, etc., shall not necessitate, at most, more than a momentary stoppage.

(3) Arrangements must be made so that all the valves in the cylinder head can be rotated on their seats by hand.

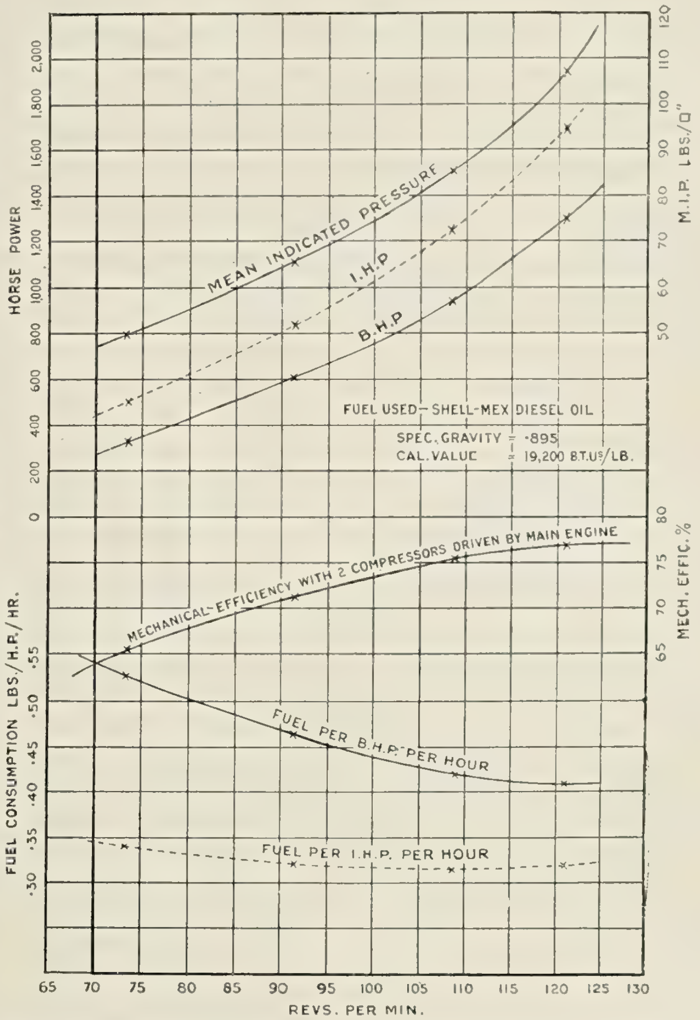


Fig. 3.—Trial Results of Beardmore-Tosi Diesel Engine, M. S. Pinzon

(4) All the main parts, including pistons, must be completely accessible.

(5) The failure of any one or two fuel pumps, supplying fuel under pressure to the main cylinders, must not necessitate a stoppage.

(6) The subject of main engine flexibility, the maneuvering gear, valve setting, and the proportioning of the flywheel, and the whole question of starting or maneuvering air supply must have greater attention than in the case of a twin-engined vessel.

(7) The engine shall be capable of being readily maneuvered by one operator.

As with steam installations, so with motor machinery, the subject of the auxiliaries, both deck and engine room, is only now receiving the attention demanded by its vital importance.

*Paper read at the sixty-third session of the Institution of Naval Architects, London, April, 1922.

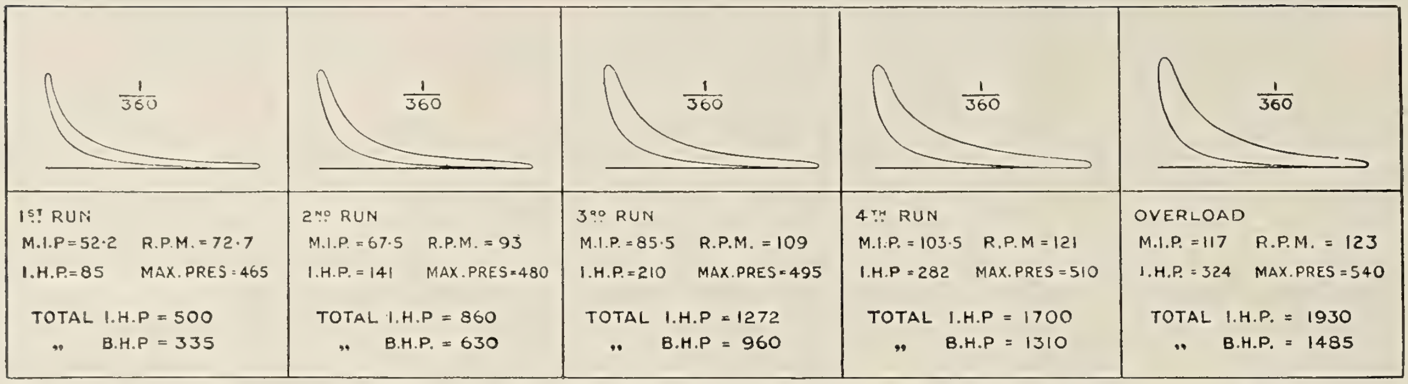

Fig. 4.—Beardmore-Tosi Marine Diesel Engine, M. S. Pinzon. Indicator Cards Taken During Progressive Speed Trials

With motorships, the rival claims of an electric or steam drive still form, and are likely to continue to prove, debatable ground. The alternative of an electric engine room and steam-driven deck machinery is possible, and may commend itself in certain cases. In Table III is given a comparison of the consumption of fuel in similar vessels, one a steamer and the other a motorship, on the same trade. The total consumption of coal is five times that of oil (by weight) in the latter taken over a whole voyage, and is achieved by the utilization of all electric machinery for deck and engine room auxiliaries, deriving current from Diesel-driven auxiliaries. With steam auxiliaries on the motorship, on this trade, the fuel consumption would only be one-third (not one-fifth) that of the steamship.

Steam vs. Motor Driven Auxiliaries

Table III emphasizes clearly the importance in a steamer of the fuel consumption attributable to the auxiliaries generally, and in such conditions as in a coasting trade, in particular, the fuel consumption of the deck machinery. Whereas at sea the ratio of coal to oil for all purposes is 4 to 1, in port this ratio is over 10 to 1, if fires are "banked." A small oil-fired boiler is generally required for the heating of the accommodation and of the oil fuel, although the former can be carried out by electric radiators, and if only a small quantity of oil is carried, exhaust gases can be utilized for heating it.

There is probability of the general adoption in future of a reasonable utilization of waste heat with Diesel marine installations, whereby oil fuel and accommodation heating can be carried out entirely by the main engine exhausts when at sea and partially, at any rate, by the auxiliary exhausts when in port.

The subdivision of the requisite total Diesel electric generator capacity and the desirable margin to be legislated for is an interesting point. Sometimes two generator engines and in a number of twin screw ships four have been fitted. In Table IV the actual electric loads on the M.S. *Pinzon* under various conditions have been tabulated. In general, three sets are preferred, one to be in action normally at sea and in port, and two when maneuvering or working cargo fully, one serving as a stand-by. Three such sets of 50 kilowatts each meet the case shown in the table and only rarely does the minimum load fall substantially below half the power of one unit, a proportion desirable for good working conditions with such machines.

It is seen that the maneuvering load is the highest, even when it may be arranged that the auxiliary compressor is slowed down, if and when the windlass load comes on, and that the radiators may be cut out, if necessary. The maneuvering load comes within the capacity of two generators.

The greatest individual load is the auxiliary compressor required to make up starting air. This machine is of sufficient capacity to supply the main engine with injection air

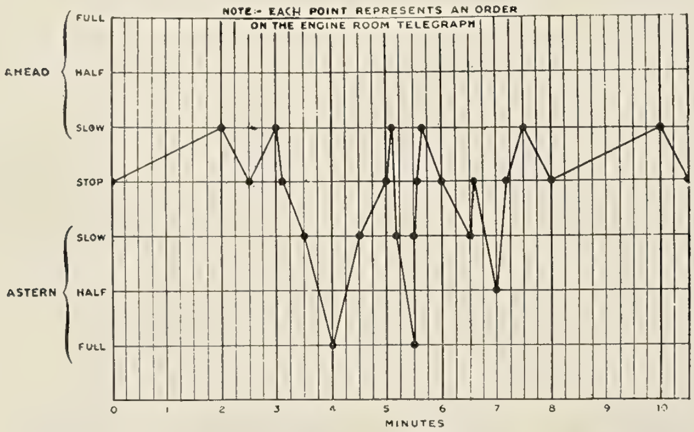

Fig. 5.—Diagram Showing Orders Carried Out on January 13, 1922, Between 6.2 P. M. and 6.125 P. M.

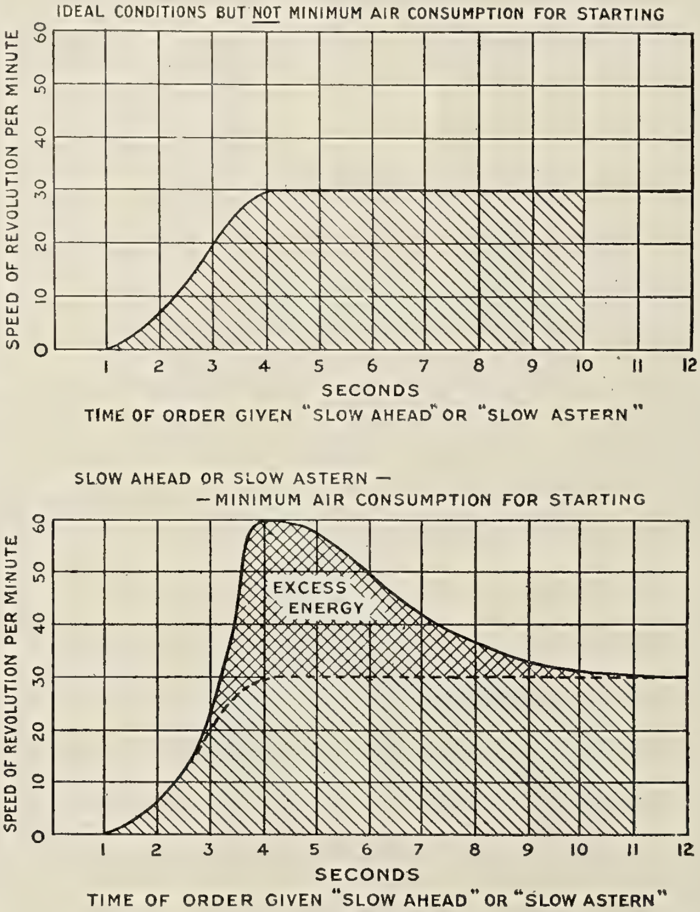

Fig. 6.—Diagrams of Starting, M. S. Pinzon

at full power in emergency, should both the main engine-driven injection compressors be out of action.

Starting Air Storage Capacity

The conservation and replenishment of starting air is a subject of vital importance with internal combustion machinery, as the ability to maneuver the ship is lost if a sufficient quantity and pressure of air are not always available to start the main engine.

Apart from the subject of conservation, reasonably rapid replenishment must be arranged for, as it is possible for a large quantity of air to be lost, as, for instance:

(i) If the exhaust valve of the cylinder into which starting air is being admitted should be hung open;

(ii) If one or more starting air valves in the cylinder head hang open;

(iii) Or, if the engine maneuvering gear should jam in the six or three cylinders on air position and other means not be immediately adopted to shut off the air.

As an example of the demand made upon the starting air storage capacity, two extracts from the log of the M.S. *Pinzon* are given (Tables V and VI) when entering Dalmuir Basin and when navigating up the Bilbao River in Spain. In Fig.

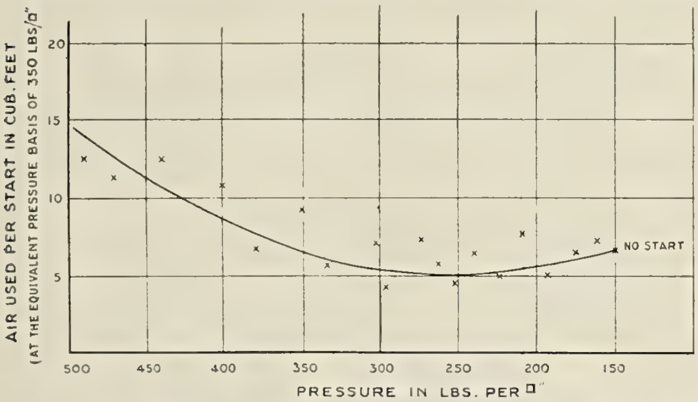

Fig. 7.—Amount of Starting Air Used by Main Engine at Various Pressures of Air Supply

5 is shown diagrammatically 10 minutes of intensive telegraph manipulation involving ten starts of the main engine (extracted from the log given in Table V).

There is one characteristic of these extracts and similar entries in the log to which reference might be made, and that is the prevalence of the repetition of the *motif*, "slow ahead, stop, slow ahead, stop" (see particularly Table VI) having the effect of propelling the ship by repeated thrusts rather than by a sustained effort. It might be suggested that the mimimum sustained power possible with the main Diesel engine is excessive. This is not so. The engine has been run for considerable periods at 24 revolutions per minute corresponding to a maximum speed through the water of 2.5 knots, when full way has been obtained, and a piston speed of 150 feet per minute, giving a ratio of maximum to minimum piston speed, or speed of revolution of 122.5 to 24 or 5.2 to 1. It is difficult to foresee any substantial improvement upon this result, since regular firing of the very minute charges of oil fuel can hardly be expected at a lower piston speed, without some substantial increase in complication, as would be involved, for instance, by preheating the induction air.

This extremely and exceptionally low speed of piston of 150 feet per minute is attained by correct combustion-producing means and by the fitting of a flywheel with suitable momentum effect.

Function of the Flywheel

As is now recognized by Lloyd's Register, the fitting of a fully proportioned flywheel isolates the thrust, intermediate and propeller shafts from the variation of engine-turning moment. The crankshaft is also equally protected from shocks, which might otherwise be transmitted from the propeller. Such a flywheel has no deleterious effects, when starting up or reversing. Momentum is first given by an elastic medium—compressed air—and during a sudden reversal which can be carried out in less than 10 seconds, with full way on the ship, the starting air on being admitted astern, if the engine compression has not already brought the engine to a stop, gently pulls the engine up and gives the initial impulses in the opposite direction.

The diagrams (Fig. 6) show the only remaining justification with modern Diesel engines for the charge of lack of flexibility. When starting up, especially with a view to doing so on the minimum expenditure of compressed air, fuel injection is commenced early and the engine accelerates to "half

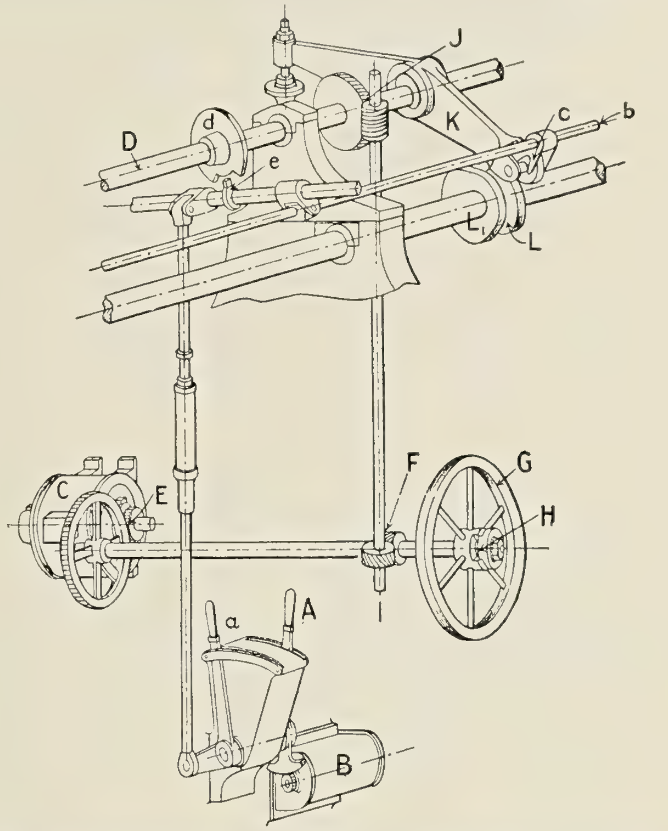

Fig. 8.—Diagrammatic Perspective Arrangement of Beardmore-Tosi Main Engine Starting and Reversing Gear

speed" before retarding to "slow." The total amount of impulse given to the ship is, therefore, approximately twice the ideal. The reconciliation, therefore, of the two somewhat conflicting aims of minimum compressed air used and minimum speed of revolution during starting, without undue complication of the maneuvering gear, is worthy of close study.

It will be found with every type of engine that there is a pressure of compressed air most suitable for starting with the minimum expenditure of air storage energy.

Curves in Fig. 7 show some records and indicate that with pressure between 250 and 350 pounds per square inch the loss of air is a minimum. Whatever the storage pressure—500 pounds per square inch with the *Pinzon*—a reducing valve to ensure that the pressure on the engine side of the air supply is not greater than 350 pounds per square inch, or other means such as working on one of a number of reservoirs, will facilitate the conservation of air.

To consider the replenishment of the storage, Appendix I gives data obtained.

Making the assumption that one start per minute will be the maximum required, over any appreciable length of time, and as the receivers fitted have a capacity of forty starts without recharging—which will cover any exceptional number of starts called for during a short period—it is shown, and has been proved in practice that:

(1) Neglecting the excess injection air from the main engine amounting to 2 cubic feet of free air per revolution of the main engine, there is available air storage and means for replenishment capable of sustaining one maneuver per minute continuously.

(2) If the main engine makes 75 revolutions each move, its excess injection air on being tapped off to the starting bottles will restore what has been taken for the start.

Analyzing a number of logs of "stand-bys," it is found that the average of one maneuver per minute is not exceeded. The average "move," however, is of much less than 75 revolutions, so that actual conditions are a combination of (1) and (2) above, but condition (1) must be satisfied in order:

(*a*) To give a stand-by in case of breakdown, with the main engine injection compressors.

(*b*) To cope with the demands for air for starting during a short spell of maneuvering, calling for more than one move per minute, if air has been lost for any reason.

(*c*) To supply starting air when the main engine injection compressor is either out of action or is working inefficiently and giving no excess air to the starting receivers.

In regard to the actual handling of the engine, see No. (7), page 373, the method of operation and the nature of the gear required will be clear from an inspection of the perspective diagrammatic arrangement given in Fig. 8.

Operating Gear

The starting and reversing of an engine operating on the 4-cycle principle have been brought to the simplest terms, consistent with operation from the usual starting platform. Whatever may be permissible with a twin screw ship, it is considered essential with a single screw installation that the controls should be on the engine room floor level, and the major portion of the gear (as illustrated in Fig. 8) serves to bring the controls to the usual location.

The simplicity of moving the rollers fore and aft, instead of the camshaft, will be appreciated.

Single screw Diesel machinery for the average cargo carrier will be much developed in the near future and the lines of design which will be followed will tend decreasingly to demand a compromise between the best propeller and a smaller and more compact engine, especially with the larger ships.

Speeds of revolution will become standardized as with the steam engine and longer stroke engines will be built. The weight of machinery, the space occupied and the cost will be greater, which will be more than compensated for by the extra accessibility, a built-up crankshaft and a considerably better average propeller performance.

Starting

The hand lever A controlling the starter B of the 5-brake horsepower electric motor C driving the fulcrum shaft D through the media of spur gearing E, spiral gearing F, to which hand wheel G—the speed revolution of this shaft being suitable—is clutched for hand starting at H, and worm gearing J, effects the starting of the engine by causing one-half revolution of the fulcrum shaft D.

The valve-operating levers K are eccentrically mounted on the fulcrum shaft D, the rotation of which causes their roller ends, for starting, to be depressed on to, or for stopping, raised from their respective cams, L for ahead and L_1 for astern.

This lowering or raising of the roller ends of the valve levers K is carried out in such a sequence, as controlled by the angle of the eccentrics, to cause the order of starting to be as follows:

Stop—all rollers clear of cams.

6 cylinders on air—6 air valve rollers on cams.

3 cylinders on air; 3 cylinders on fuel—3 air rollers raised and 3 fuel rollers depressed.

6 cylinders on fuel—3 remaining air rollers raised and 3 remaining fuel rollers depressed.

Reversing

The hand lever *a*, through the medium of links and levers, causes fore and aft movement of the reversing shaft *b*, upon which forks *c* are mounted.

Fore and aft movement of this shaft *b* pulls the rollers along their pins in the wide fork end of the levers K from opposite the ahead cams such as L to opposite the astern cams such as L_1 or vice versa.

A disk *d*, with a gate, is keyed on to the fulcrum shaft D, through which pointer *e* must pass before the rollers can be moved fore and aft for reversal.

The gate in the disk *d* is only opposite the pointer *e* when the valve gear is in the stop position, i.e., all the rollers are clear of the cams.

This is the only interlockment in the gear.

Appendix

M.S. *Pinzon—Data Relating to Compressed Air—Time to Start from Conditionally "No Air in Ship."*

(a) When *Running the Emergency Compressor* of 12 cubic feet per minute swept volume.
Time to fill one blast bottle and one starting bottle for auxiliary generator engine to
800 pounds per square inch = 26 minutes 50 seconds.
1,000 pounds per square inch = 35 minutes 30 seconds.

(b) When *Running the Auxiliary Compressor.*
Time to fill one starting air reservoir to 500 pounds per square inch = 19.5 minutes.
Additional time to top up one blast bottle from 500 to 1,000 pounds per square inch = 2.5 minutes.

(c) *Air Available When Maneuvering Main Engine.*
Air from one main engine-driven compressor (the other being sufficient for blast supply) = 2 cubic feet per revolution.
Excess air from auxiliary engines (estimated at one-third of air made) = 27.5 cubic feet per minute.
From auxiliary compressor = 176 cubic feet.

(d) Assuming no air is taken from main compressors, we have 174 cubic feet free air per minute available. This is equivalent to approximately 7 cubic feet air at 350 pounds per square inch per minute. The main engine uses from 5 to 7 cubic feet of air at 350 pounds per square inch per start or reversal, so that there is sufficient air available to allow of one maneuver per minute continuously, neglecting any surplus air made by main engine.

(e) 70-75 revolutions of main engine supply air for each maneuver (one compressor used wholly for blast), so that, if the main engine is allowed to make 75 revolutions for every maneuver, the starting air can be maintained by the main engine without using any auxiliary supply.

Table I.—M. S. Pinzon

Particulars of Ship and Machinery—Description.

Ship.—Displacement = 3,300 tons. Length = 240 feet. Breadth = 38 feet. Depth = 18 feet.
Winches.—Six fitted, each 16 horsepower.
Windlass.—One fitted, 50 horsepower.
Main Engine—Beardmore Tosi 4-cycle, single-acting, 6 cylinder, 629 millimeters (24¾ inches) bore; 975 millimeters (38⅜ inches) stroke; 1,250 brake horsepower at 120 revolutions per minute.
Main Injection Air Compressors.—Two 3-stage. Swept volume per revolution 1 compressor = 2 cubic feet. Swept volume per revolution, 2 compressors = 4 cubic feet.
Auxiliary Compressor.—Three-stage. Capacity first speed = 88 cubic feet per minute free air. Capacity full speed = 176 cubic feet per minute free air.
Emergency Compressor.—Swept volume = 12 cubic feet per minute free air.
Starting Air Receivers.—Three at 70 cubic feet each = 210 cubic feet. Maximum working pressure, 500 pounds per square inch.
Main Engine Blast Bottle.—One working, one spare fitted. Capacity of one bottle = 5 cubic feet. Maximum working pressure, 1,000 pounds per square inch.
Auxiliary Generators.—Two fitted, each 50 kilowatts, Diesel driven. Engines of trunk piston type, 2-cylinder, 4-cycle, 75 brake horsepower, 250 revolutions per minute.
Compressors (Aux. Gen.).—For 1 generator engine, swept volume of compressor at 250 revolutions per minute = 41.2 cubic feet per minute free air. 2 generator engine, swept volume of compressor at 250 revolutions per minute = 82.4 cubic feet per minute free air.
Starting Bottle (Aux. Gen.).—Two per engine capacity = 3.54 cubic feet each. Maximum pressure, 1,000 pounds per square inch.
Blast Bottle (Aux. Gen.).—One per engine capacity = 1 cubic foot each. Maximum pressure, 1,000 pounds per square inch.
Propeller.—Diameter = 12 feet 6 inches. Pitch = 11 feet.

Table II.—M.S. Pinzon.—Results of Sea Trials

Fuel Consumption per Day (in Tons) for all Purposes.

Speed of ship (fully laden), knots	9	10	11
Revolutions per minute (main engines)	95	105	115
Fuel consumption, all purposes (tons per day)	3	4	5.2

Table III.—M. S. Pinzon and Similar Steamship—*Comparison of Fuel Consumptions at Sea and in Port.*

Steamship—

Triple-expansion engines, single screw.
Ship, 270 feet by 38 feet by 18 feet; draft, 17 feet 5 inches.
Voyage, London to Spanish port.
Indicated horsepower, 1,073.
Revolutions per minute, 75.8.
Speed of vessel, 9.35 knots.
Coal used per day, *for all purposes*, 17.42 tons.
Coal used by auxiliaries per day, 2.5 tons.
Coal used in port per day, discharging and loading, 3 tons.
Banked fires, used per day, 16 days on average voyage, 1 ton.

Motorship Pinzon—

Diesel engines, single screw.
Ship, 240 feet by 38 feet by 18 feet; draft, 17 feet 6 inches.
Voyage, Glasgow to Spanish ports.
Diesel indicated horsepower, 1,290.
Equivalent steam indicated horsepower, 1,170.
Revolutions per minute, 106.
Speed of vessel, 10.2 knots.
Oil used per day, *for all purposes*, 4.5 tons.
Oil used by auxiliaries per day, 0.2 ton.
Oil used in port per day, discharging and loading, 0.37 ton.

The American Bureau of Shipping has under preparation a set of rules to govern the construction of river, harbor and canal craft, with a view of taking up the classification of same.

Diesel Electric Ferryboat for Service in San Francisco Harbor

The *Golden Gate*, which will be the first large automobile ferryboat in this country to be equipped with Diesel engine electric drive, is expected to begin operations in San Francisco Bay early in the coming summer. She will form part of a fleet of ferryboats operated by the Golden Gate Ferry Company, which will offer a fast service between Sausalito and San Francisco, to form a link between the northern and southern highway systems of the State of California.

The *Golden Gate* will have an overall length of 220 feet and a displacement length of about 207 feet. Her propelling equipment will consist of two 500 brake horsepower Werkspoor Pacific Diesel engines each directly connected to a General Electric Company 360 kilowatt, 250 volt, shunt wound direct current generator. The power from these generators will be delivered to two 750 horsepower, 500 volt, 145 to 180 revolutions per minute shunt wound motors, one on each propeller shaft. There will be a 35 kilowatt, 115 volt exciter direct connected to each engine generator and used to furnish power for lights, excitation and engine room and deck auxiliaries.

The boat will represent a radical departure in ferryboat construction, being the first double ended one where each propeller will be driven separately. The most economical method of propelling such a boat is to have the majority of the power concentrated on the propeller that is actually driving it. Electric drive is the only way in which this can be satisfactorily accomplished and still use the same prime mover for both directions of travel eliminating duplicate units for ahead and astern travel.

The flexibility of control which is a feature of Diesel engine electric drive has also been fully taken advantage of in this boat. She will be equipped with Ward Leonard control, with stations in both pilot houses as well as in the engine room.

Motorship Californian of the American-Hawaiian Steamship Company

Sea Trials of the Motorship Californian

Thirteen Knots Speed Attained With Fuel Consumption of 0.31 Pound Per Indicated Horsepower

THE operating records given below, taken during the engine builder's trials of the American-Hawaiian Steamship Company's motorship *Californian* on May 1 and 2, offer an excellent opportunity to study the possibilities of American-built motorships of large size.

A complete description of the *Californian* was given in the February issue of MARINE ENGINEERING AND SHIPPING AGE and only the general details will be repeated here. The vessel was built at the yard of the Merchant Shipbuilding Corporation, Chester, Pa., and all machinery, both main and auxiliaries, at the yard of the William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa.

In general, the *Californian* has the following characteristics:

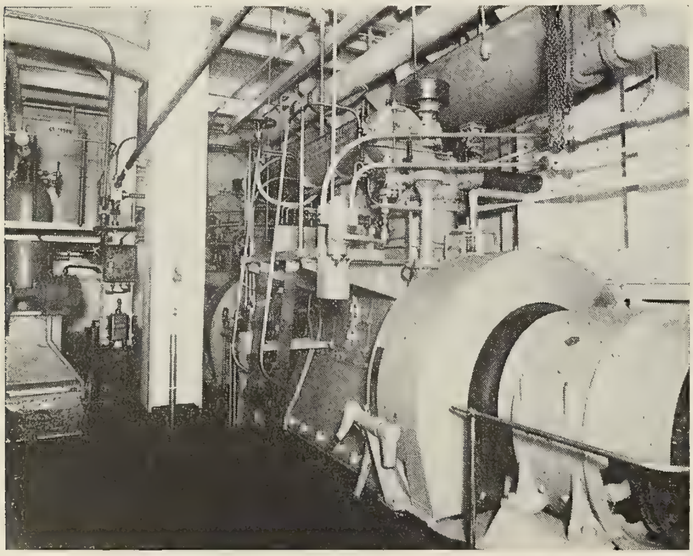
Length, overall	461 feet 7½ inches
Length, between perpendiculars	445 feet
Breadth, molded	59 feet 8 inches
Depth, molded to shelter deck	39 feet
Draft, loaded	28 feet 6 inches
Draft, light	10 feet 7 inches
Block coefficient	0.76
Midship section coefficient	0.986
Longitudinal coefficient	0.77
Speed, loaded, knots	11.5
Cruising radius, nautical miles	25,000
Framing	Transverse
Class	✠ 100 A.1. Lloyd's

The propelling machinery consists of two four-cycle Diesel engines built in accordance with the Burmeister and Wain system, having a total of 4,500 indicated horsepower and a designed speed of 115 revolutions per minute. The auxiliary machinery includes four Diesel engines direct connected to Diehl generators, each operating at a speed of 300 revolutions per minute and delivering 100 brake horsepower.

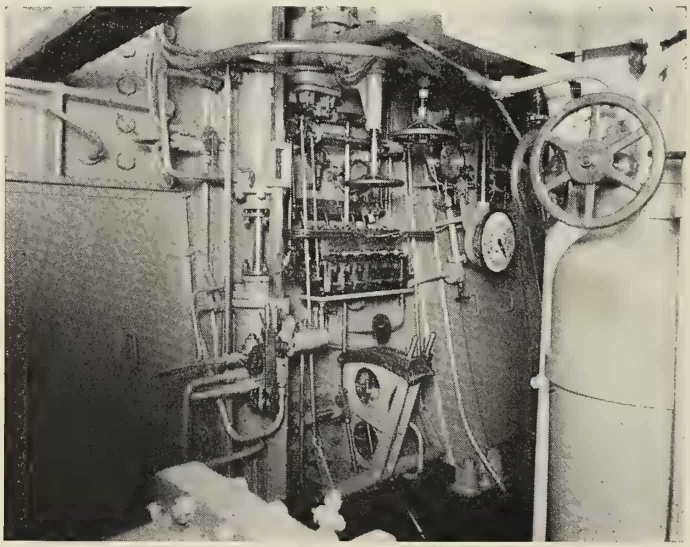
TESTS ON THE MEASURED MILE

An early start was made on the morning of May 1 from the yards of the Cramp Company and, after compass adjustments were made, three runs were carried out over the measured mile course with the following results:

Revolutions per minute, mean	114.62
Mean indicated pressure, main engines	82.8



65-Kilowatt Auxiliary Generator Set



Maneuvering Platform, Port Engine Room

Indicated horsepower, mean, main engines	4,330
Speed, knots, corrected for tide	12.57
Slip of propellers	5.4 percent
The maximum speed made over the mile course (uncorrected for tide) was	13.9 knots

On the second day a six-hour continuous run was made, which consisted in running 2½ hours out to sea and back and 3½ hours up the Delaware Bay and river. During this run, the draft of the vessel was 8 feet 3 inches forward and 18 feet aft, thus making the drag so great that the speed of the vessel was sensitive to the depth of the water. For this reason, and because it was necessary to follow the ship channel, the last two hours of the run were not considered in determining the consumption test, the amount of fuel oil used being taken only for the first four hours when the conditions of draft of the vessel were more uniform. In the open sea, the engines turned over at a maximum of 119.25 revolutions per minute without any change in the control of the engine. This engine speed corresponds to slightly over 13 knots. The results of the four-hour consumption test are as follows:

Oil consumption, main engines and one auxiliary engine	1,372 pounds
Indicated horsepower, main engines	4,417
Kilowatt load, auxiliary engine	50
Revolutions per minute, mean, main engines	117.58
Corresponding speed from standardization runs	12.9 knots
Mean indicated pressure, at corresponding speed from standardization runs	82.13
Oil consumption per indicated horsepower, main engines, only (all purposes)	0.31 pound

During the first half hour of the run the consumption was 0.328 pound per indicated horsepower due to the fact that the engines were not yet warmed up and this amount increases slightly the mean consumption for the four hours. For the total six hours the results are indicated below:

Indicated horsepower, main engines	4,445
Revolutions per minute, mean, main engines	117.29
Mean indicated pressure, main engines	82.80

It will be seen from these figures that the mean revolutions per minute are lower and the indicated horsepower higher for the six hours than for the four hours due to the greater resistance to hull in the shallower water, as previously stated, during the latter part of the run.

After the four-hour consumption test was completed the power of the engines was increased slightly to give their normal mean indicated pressure, which is 85.6 pounds, corresponding to the designed indicated horsepower of 4,500 at 115 revolutions per minute with the following results:

Mean indicated pressure, both engines	85.3
Revolutions per minute, mean, both engines	118.26
Indicated horsepower, mean, both engines	4,610

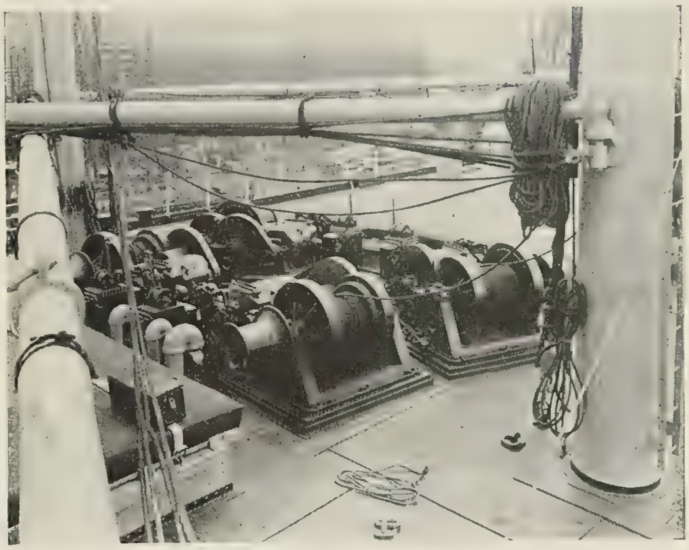
During this run, all inner bottom tanks were filled with oil as well as the peak tanks with water in order to have the screws completely submerged. Under these conditions, the mean draft was 13 feet 1½ inches taken in fresh water or 12 feet 10 inches mean, corrected to salt water, which corresponds to 6,750 tons displacement.

Final Adjustments Made to Machinery

After completion of the trials the *Californian* returned to the Cramp Company's yards, where a final examination of the machinery was made and adjustments carried out on the engines. The finishing coat of paint was also put on the engines, since this had been omitted until after the trials.

On May 5 the vessel was taken over by the American-Hawaiian Company and sailed for New York to be dry docked for cleaning and painting of the ship's bottom, which was not done before the trials.

On the run to New York a four-hour consumption test was made with the following results:



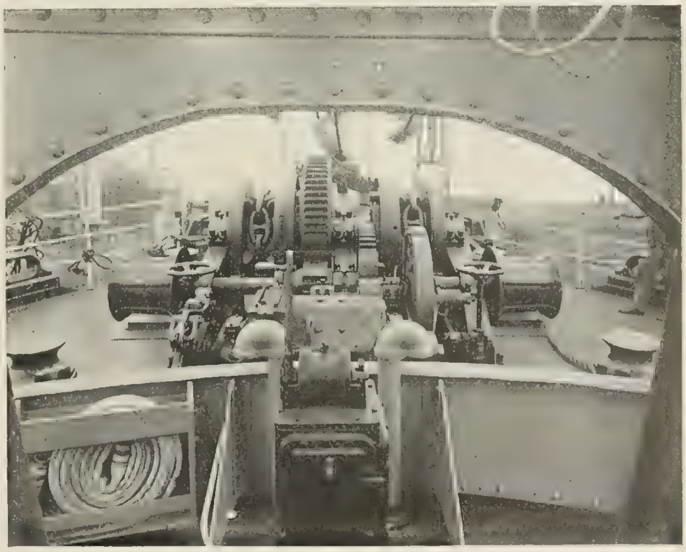
Group of Electric Winches at After Kingposts

	Port Engine	Starboard Engine	Mean
Revolutions per minute	115.95	116.25	116.10
Mean indicated pressure	85.65	84.90	
Indicated horsepower	2,267	2,256	4,523
Total gallons			738
Gallons per hour			184.5
Pounds of oil per hour			1,400
Oil per indicated horsepower, main engines, all purposes			0.309

The draft of the vessel on leaving the yard was 7 feet 10 inches forward, 18 feet 5 inches aft, or a mean of 13 feet 4½ inches which, corrected to salt water, was 12 feet 10 inches, the same as on the builder's trials.

All fuel tanks in the inner bottom were completely filled before leaving Philadelphia, there being a total of 9,426 barrels on board. On arrival in New York the draft was 8 feet 1 inch forward and 17 feet 6 inches aft, or a mean of 12 feet 9½ inches. The oil used on this trial was supplied by the Texas Company as it was in the case of the builder's trial, and had the following analysis:

Specific gravity at 60 degrees F.	0.913
Baumé, corresponding	23.5 degrees
Flash open cup	253
Fire	273
Viscosity Staybolt at 100 degrees F.	152
Sulphur	0.60 percent
Asphalt insoluble in naphtha	1.11 percent
B. T. U.	19,120

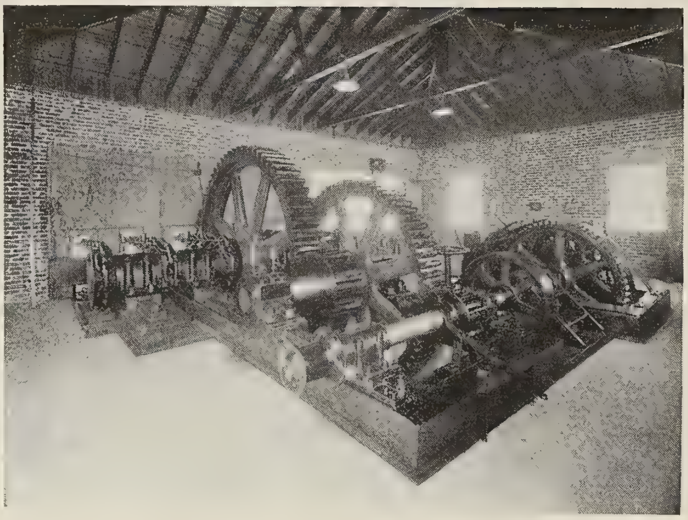


View of the Windlass on the Forecastle

It is interesting to note that the main engines were not run on the test stand in the builder's shops, as is generally the custom with this type of machinery, and the excellent results obtained on the trials justified this omission. The only adjustment required on the engines was in the fuel cam throws, which were quickly made since these were not integral with the fuel cams proper.

With the exception of the fact that there are four auxiliary Diesel generator sets instead of three, the machinery on the *Californian* is practically a duplicate of the motorship *William Penn*. The additional set was necessary because of the larger number of winches employed.

It is expected that the economy of operation will be improved after the ship has been in service for awhile when all bearings and liner surfaces are run in and the finer adjustments made to the fuel control. It is noteworthy that no bearings were raised during the trials nor adjustments made.



Hauling Machinery of 5,000-Ton Railway Dry Dock

5,000-Ton Railway Dry Dock at Norfolk

WITHIN the last year Colonna's Shipyard, Inc., Norfolk, Va., has put into operation a new railway dry dock with a lifting capacity of 5,000 tons weight, making it the largest railway dry dock on the Atlantic Coast. This dock, which is capable of handling the 10,000-ton deadweight class of ships, has added 40 percent to the dry docking facilities of the port of Norfolk.

The dock was designed and constructed by The Crandall Engineering Company, dry dock engineers, Boston, Mass., according to their standard designs. The track is of the four-way type, of timber construction, heavily bolted and braced, resting on a foundation of yellow pine piling driven to refusal and accurately cut to the correct gradient. The track is railed with flat steel plates. The cradle moves along this track supported on connected free rollers.

The cradle which actually carries the ship is of heavy yellow pine timber construction. The length over the keel blocks is 360 feet, which, with a fantail 20 feet long, gives an over-all length of 380 feet. The width between the over-all is 70 feet with 63 feet in the clear between the uprights. At mean high tide ships can be docked drawing 14 feet forward and 19 feet aft. It is built up aft by columns and heavy bracing so that the keel blocks conform to the usual slope of the ship's keel when in light condition, thus avoiding any distortion or stress to the ships.

On each side of the cradle are uprights supporting a docking platform conveniently located for handling lines and centering ships when being docked. On this platform are located the hand winches for pulling the bilge blocks against the ship. The bilge blocks are of patent releasing type, enabling one man to readily release and replace a bilge block under full load.

The cradle is operated by six hauling chains of open-link type attached to the cradle by an equalizing gear which assures the stress in the several chains being always the same. These chains are operated by a powerful hoisting machine, electrically operated, enabling a full capacity ship to be dry docked ready for repairs in 45 minutes. The machinery is of special design with heavy gearing and shafts. It is equipped with an automatic brake which stops the machine, in case the electric circuit is broken.

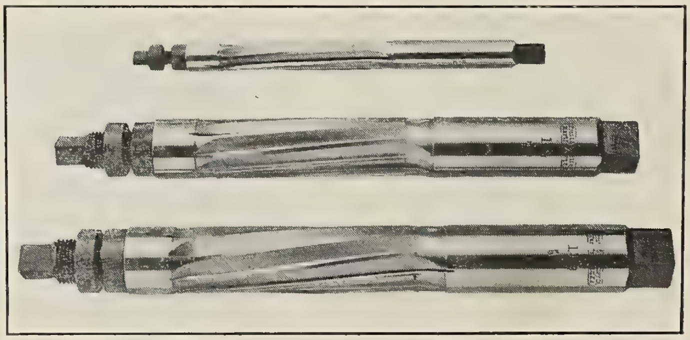
Spiral Fluted Expansion Hand Reamers

THE Pratt & Whitney Company, Hartford, Conn., has added to its line of small tools a spiral fluted expansion hand reamer. Expansion reamers have always found favor because of their long life and the adjustable feature that permits covering a range of sizes with one tool. Oversize or undersize holes can be reamed by simple adjustments. The advantages of the spiral flute with its free and clean cutting characteristics are obvious.

All reamers are equipped with lock nuts to hold the size and safety stops which prevent over-expansion and indicate positively when the maximum limits have been reached. Three sizes of spiral fluted expansion hand reamers are shown in the illustration, including ½-inch, 1-inch, and 1⅛-inch. These reamers are made in all the regular sizes.

The spiral flutes afford a distinct advantage in reaming holes having keyways in them. The straight flutes catch and bind on the edges, but the spiral continuous shearing cut rides safely over the corners assuring a hole cut to size.



Pratt & Whitney Spiral Fluted Expansion Hand Reamers

Striking Features of Motorship Building in Europe

Remarkable Doxford Engine Development—More Motor Passenger Liners—Two Versus Four Cycle Diesels—Single Screw Motorships

By Our Special London Correspondent

THE fact that the construction of the Doxford opposed piston oil engine (perhaps the most interesting marine motor now built) is to be taken up at once by the Sun Shipbuilding Company of Chester, Pa., gives added interest in America to the noteworthy developments taking place in connection with this engine. Arrangements have also been made for it to be built at Workman, Clark and Company's Belfast works, and also by the Fairfield Shipbuilding & Engineering Company, on the Clyde.

It will be remembered that two Doxford engined ships have been completed and both of these recently completed their first voyage, that of the *Yngaren* (belonging to the Transatlantic Company) being a 6 months' trip practically round the world, while the first voyage of the *Dominion Miller,* owned by Furness, Withy and Company, was only between British and American ports. In the first engine, the fuel consumption was admittedly somewhat disappointing, working out at about 0.44 pound per brake horsepower hour. As a consequence the Doxford engineers set to work with the object of so modifying the design as to improve combustion and to reduce consumption. The result is that the engine of the *Dominion Miller,* the second ship, is apparently much more efficient and whereas the fuel consumption of the *Yngaren,* carrying about 9,300 tons at a speed of 11 knots, worked out at 11.6 tons daily, that of the sister ship, at nearly the same speed, was under 10 tons daily.

Fuel Consumption Reduced in Third Doxford Engine

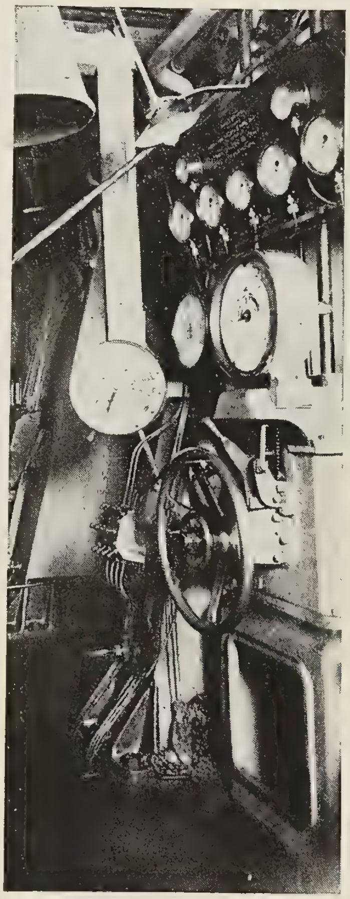
With the third engine that has just been built, and upon which special tests have been made, an even more satisfactory result is achieved and it is stated that fuel consumptions under 0.4 pound per brake horsepower hour are reached, these being quite equivalent to, if not superior to, those attained with four cycle motors.

These low consumptions have been attained by improvements in two directions. In the first place, the spray valves have been modified, and, secondly, the scavenging port system has been altered. By this means the fuel is sprayed in at a pressure of 8,000 to 10,000 pounds per square inch and meets with a volume of air at about 300 pounds per square inch pressure, whirling round with high velocity. Apparently the combustion is as perfect as is obtainable with any Diesel

motor, and it is stated that the exhaust temperature does not exceed 300 degrees. This is with a four cylinder engine of 3,000 indicated horsepower or about 2,700 brake horsepower and Doxfords believe that they have by no means reached the end of their experiments. They are now willing to guarantee six cylinder engines of 6,000 brake horsepower and it may not be long before motors of this size are constructed.

Popularity of Single Screw Ships

One of the most striking features of European motorship development is the increasing number of single screw vessels which are now being placed in commission. It appears that, once shipowners have overcome the idea that motorships are not as reliable as steamers, they prefer to have single screw craft, in spite of the fact that many Diesel engine manufacturers, and in particular Burmeister and Wain, are strong in their contention that a twin screw vessel can be quite as efficient from the propulsive standpoint as a single screw design. Moreover, it appears that large twin screw machinery is probably cheaper and occupies less space than a single screw plant on account of the fact that a single Diesel engine of say 4,000 horsepower is heavier than two sets of 2,000 horsepower. For the same propulsive efficiency a single screw craft must have machinery operating at lower speed than when two engines are fitted and this naturally reacts upon the weight and the cost.



Controls of the Doxford Engine

Nevertheless the shipowners' standpoint is that single engines are preferable on account of the smaller cost of upkeep and the fewer attendants required. Hence the great interest now being shown in motor vessels equipped with one engine. So far as reliability is concerned, there appears to be no reason against the single screw ship as instanced by the voyage mentioned above of the *Yngaren* when during six months no troubles of any consequence were experienced. The chief difficulty was in connection with the spray valve which had to be renewed about every four days, resulting in a stop of about one hour's duration in each case.

Among other single screw craft that have just been completed is Beardmore's first oil engined vessel, the *Pinzon,* provided with one of their Tosi type six cylinder Diesel engines of 1,250 brake horsepower. In this design some criticism was aroused on account of the fact that two air compressors were provided on the engine, each of which was capable of supplying all the injection air required. The builders' defense is that it is highly desirable on a single screw vessel to duplicate the injection system but whether shipowners, as a rule, will agree to this extra expense is somewhat doubtful.

Two Werkspoor engined single screw ships were also completed during April, one being the first motor vessel for the Netherland Steamship Company, the *Rhea,* provided with an 850 brake horsepower engine, and the other the *Segovia,* equipped with North Eastern Werkspoor machinery built by the North Eastern Marine Engineering Company, the leading reciprocating steam engine builders on the Tyne.

Two Cycle or Four Cycle Engines

A very heated controversy is now raging through the medium of the engineering and shipbuilding institutions and the technical press in Europe regarding the respective advantages of the two and four cycle types of Diesel machinery. Mr. Blache, the managing director of Burmeister & Wain, is the leading protagonist of the four cycle type and vehemently denies that this is ever likely to be displaced by the two cycle construction. In his opinion the high mean effective pressures claimed by the two cycle engine builders (100 pounds per square inch and upwards) are undesirable in Diesel cylinders and, if shipowners require to work at these pressures, four cycle engine builders would meet the same conditions. He therefore thinks that two cycle engines are rated too high and are unable to maintain their designed output at sea in the same way as is possible with a four cycle engine. Furthermore, he is of opinion that where port scavenging is adopted in two cycle engines—and this is well nigh universal—lubricating oil consumption must be excessive owing to its escape through the exhaust ports and he also objects to the employment of piston rings for a purpose other than that for which they are essentially designed.

The designers of the Sulzer engine retort that the characteristic of working at a high mean effective pressure is one of the peculiar advantages in the two cycle motor and that mean effective pressures exceeding 100 pounds per square inch can be maintained continuously. As a result the two cycle engine can be built more lightly and therefore cheaper than the four cycle design. Furthermore, they claim that, alone with two cycle engines, owing to the absence of exhaust valves, will it be possible to use cheap boiler oil instead of the more expensive Diesel oil. Again, the two cycle advocates aver that the limit has been reached in four cycle engine cylinder output, whereas with two cycle motors there is no reason why engines up to 12,000 brake horsepower in six cylinders should not be constructed.

Motor Passenger Liners

In spite of the shipbuilding depression, some interesting motor passenger liners are now being built, the largest being an Elder Dempster vessel for trade to West Africa, with accommodation of about 350 passengers.

This ship is over 500 feet in length and is to be provided with twin screw Burmeister & Wain machinery, built by Harland and Wolff, of 6,500 indicated horsepower, giving a speed of 13½ knots. She will, when completed, be the finest motor liner afloat and it is not unlikely that, should the clouds now hanging over the shipping industry lift, further vessels of a similar type will be laid down.

A sister ship to the *Domala,* the first motor liner for the British India Steam Navigation Company, is under construction on the Clyde and will be placed in commission before the end of the year, while the North German Lloyds are about to lay down a 9,000-ton passenger ship for trade between Germany and America. This will be a vessel of the intermediate class with a speed of 12½-13 knots and in it will be installed four cycle engines of about 6,000 horsepower.

Portland Cement Specifications Advanced to American Standard.—The "Specifications and Tests for Portland Cement," for which the American Society for Testing Materials is sponsor, have been advanced to the full status of "American Standard" by the American Engineering Standards Committee. These specifications were first approved by the A. E. S. C. as "Tentative American Standard" in 1919.

200-Ton Hammerhead Fitting Out Crane on Pier 7 at the South Yard of the New York Shipbuilding Corporation

Two-Hundred-Ton Fitting Out Crane at Camden Yard

Details of Construction and Operation of Huge Hammerhead Crane Installed at South Yard of New York Shipbuilding Corporation

To provide for the installation of heavy weights such as boilers, guns, armor, turrets, engines, etc., in ships afloat, the New York Shipbuilding Corporation, Camden, N. J., through its civil engineer, Mr. E. H. Sapp, worked out the basic features of design for a 200-ton hammerhead electrically operated fitting out crane for installation at the head of Pier 7 at its South yard. The detail design and construction of the crane were carried out by the Wellman-Seaver-Morgan Company, of Cleveland, O.

The addition of this crane gives the New York Shipbuilding Corporation the most comprehensive crane system of any industrial plant in the country. Exclusive of the locomotive cranes, the yard is now equipped with 115 cranes well distributed among the shops, storage yards, ways and outfitting piers. They vary in size from those with a capacity of 1½ tons in the joiner shop through the 35-ton gantries on the outfitting piers and the 80-ton overhead traveling crane in the storage yard to the 100-ton overhead crane which serves the main covered unit of five double ways and wet slip, and the new 200-ton hammerhead crane.

The new hammerhead crane consists of a stationary self-supporting tower carrying a vertically rotated mast on the top of which a horizontal boom is securely connected. Normally five distinct motions are provided, viz., main hoist, main hoist trolley travel, auxiliary hoist and auxiliary hoist trolley travel and boom slewing.

The main hoist is made up of two units designed to operate as one unit when lifting the maximum load. The main hoist trolley travel is also made up of two units designed to operate as one unit when handling the maximum load. By removing the main lifting beam that connects the two main lifting blocks and the shifting of two jaw clutches (one connecting each of the two units of the main hoist and the main hoist trolley travel) each hoist unit can be operated independently, allowing the handling of loads up to 200,000 pounds with only one of the units in operation. The shifting of these jaw clutches is accomplished by the operation of hand levers located in the machinery house. Each of the above motions is operated by independent motors controlled from the operator's cab.

The crane has a capacity for handling any load up to 400,000 pounds at a maximum radius of 85 feet and 60,000 pounds at a maximum radius of 125 feet from the center of the tower.

The various motions of the crane have approximately the following speeds:

Main hoist	400,000 pounds at 11 feet per minute
Main hoist (one unit)	200,000 pounds at 11 feet per minute
Main hoist trolley travel	25 feet per minute
Auxiliary hoist	60,000 pounds at 32 feet per minute
Auxiliary hoist trolley travel	100 feet per minute
Slewing motion with either maximum load at each maximum radii or the equivalent, (at 125 foot radius)	125 to 150 feet per minute

Principal Dimensions

The principal dimensions of the crane are as follows:

Maximum clear lift from top of foundation (200-ton hooks)	118 feet 0 inches
Maximum clear lift from top of foundation (100-ton hooks)	124 feet 2 inches
Maximum clear lift from top of foundation (30-ton hooks)	126 feet 4 inches
Lowest position of hooks below top of foundation	35 feet 0 inches
Minimum radius of hook from center of tower (main hoist)	30 feet 0 inches
Minimum radius of hook from center of tower (auxiliary hoist)	30 feet 0 inches
Total height of crane over all, about	164 feet 0 inches

The boom may be slewed in either direction for an indefinite number of revolutions.

Tower, Boom and Mast

The tower is rectangular and is constructed of rolled steel sections. A portal 22 feet high by 27 feet wide is provided on the two opposite sides of the base. At the top of this tower is a circular track ring in which the vertical mast supporting the boom is centered. This track ring also carries the main circular rack for rotating the boom.

The boom and mast are constructed of rolled steel sections. The forward end of the boom carries the runways fitted with A. S. C. E. section rails, upon which the two main hoist trolleys and auxiliary trolley travel. These runways are arranged with the two main hoist trolleys on the outside and the auxiliary hoist trolley in the center, allowing the auxiliary trolley to pass between.

The boom is extended to the rear of the tower forming a support for the counterweight and machinery house which contains the operating mechanisms. The boom and mast are carried by a heavy thrust bearing framed in the tower just above the main portal. The mast carries horizontal adjustable rollers so located that they roll against the circular T-rail provided on the track ring of the tower, thereby keeping the mast in its vertical position.

Main Hoist Mechanism

This mechanism is made up of two distinct units, each unit being made up of two drums driven by an electric motor through spur gear reductions. These drums are cast iron, machine grooved to receive a single hoisting line. The faces of the drums are sufficient to take the entire line without overwinding the rope. When the hook is in the lowest position there still are two complete wraps remaining on the drum. A jaw clutch controlled by a hand lever in the machinery house provides means for connecting these two units, making them operate as one unit when handling the maximum load.

The main hoist trolley travel mechanism is made up of two separate units, each unit being made up of one drum driven by an electric motor through suitable spur gear reductions. The drums are cast iron, machine grooved to receive two ropes, one winding on as the other pays out. A jaw clutch controlled by a hand lever in the machinery house provides means for connecting these two units, making them act as one unit when handling the maximum load.

Auxiliary Hoist

The auxiliary hoist consists of a cast iron drum, machine grooved to receive a single hoist line, driven by an electric motor through spur gear reductions. The face of the drum is sufficient to take the entire line without overwinding the rope. When the hook is in the lowest position there still are two complete wraps remaining on the drum.

Main and Auxiliary Hoist Trolleys

There are two trolleys for the main hoist. Each trolley consists of a structural steel framework carried on four double flanged high carbon steel track wheels. This trolley carries six cast steel sheaves 45 inches in diameter for the hoisting rope.

The hoisting blocks used in connection with these trolleys are of the four sheave type carrying a four pronged forged steel hook arranged to swivel on roller bearings. A structural steel lifting beam is furnished which is suspended from these hooks. This lifting beam in turn carries a four pronged forged steel hook arranged to swivel on a heavy roller bearing.

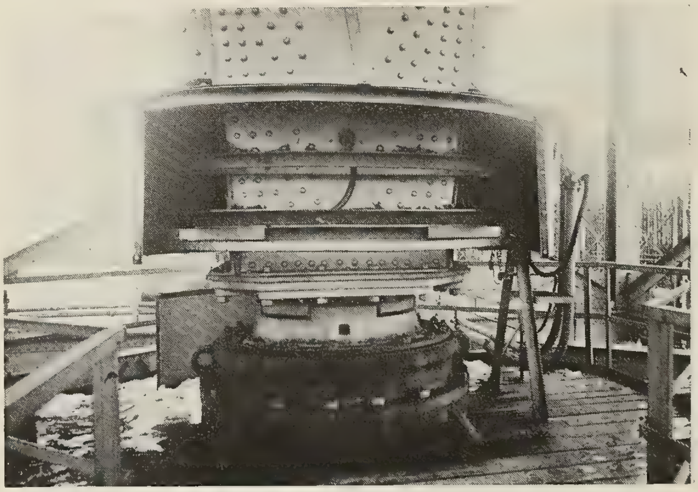
The auxiliary hoist trolley is made up of structural steel, traveling on four double flanged track wheels, and carries three sheaves. The lifting blocks in this case are of the two sheave type, 36 inches in diameter, carrying a four pronged forged steel hook arranged to swivel on a roller bearing.

The hoist and trolley travel ropes are reeved in such a manner as to maintain the hooks at a constant level when racking the trolleys. One and one-half-inch diameter rope is used for the main hoist, 1⅛-inch diameter for the auxiliary hoist, 1-inch diameter for the main trolley travel, and ⅝-inch diameter for the auxiliary trolley travel.

Slewing Motion

The mast and boom are rotated by two cast steel pinions meshing with a circular rack secured to the top of the tower. These pinions are driven by an electric motor through spur and bevel gear reductions. The vertical shafts are carried in a cast steel housing secured to the boom. To provide for equal loading on the main driving pinions, a differential unit is inserted in this mechanism.

A powerful foot brake is carried on the intermediate shaft of each hoisting unit, which is of sufficient power and so proportioned that the maximum lifted load may be held or lowered through these brakes in an emergency. The slewing



Step Bearing at Bottom of Vertical Mast, with Cover Over Electrical Conductors Partially Removed

Interior of Machinery House Looking Toward Boom

mechanism is provided with a similar foot brake, which is of sufficient power to hold the boom against a wind load of 10 pounds per square foot and will permit the boom to drift slowly when the wind pressure exceeds 20 pounds per square foot. These brakes are provided with latches, by means of which the brakes may be set and held in any position. The bands are lined with asbestos brake lining.

Electrical Equipment

The electrical equipment is designed for a voltage at the machine of 230 volts direct current, and will operate satisfactorily at a slightly higher or lower voltage. All master controllers are located in the operator's cab. Magnetic switch controllers are located in the machinery house, adjacent to the motors.

The motors are of the Westinghouse Electric & Manufacturing Company's make, series wound, mill type, totally enclosed, with fireproof insulation and armature shaft extensions on both ends. The motors are of the following approximate horsepower, based on ½-hour rating:

Main hoists	2 No. 80 M.C.	110 horsepower
Auxiliary hoist	1 No. 80 M.C.	110 horsepower
Main trolleys	2 No. 40 M.C.	27 horsepower
Auxiliary trolley	1 No. 40 M.C.	27 horsepower
Slewing	1 No. 60 M.C.	65 horsepower

The above motors are equipped with magnetic switch type controllers with drum type master switches, together with the necessary cast grid resistance. Those for the auxiliary and main hoists are arranged for dynamic braking, while those for the main and auxiliary trolleys and slewing are of the plain reversing type.

The main hoist master controllers are so arranged that, if the two main hoists are clutched together and used as a single unit, the master switches can be mechanically connected to operate as a single unit. The same is true of the main trolley master switches.

There is located in the operator's cab a protective panel equipped with a main line knife switch which disconnects all apparatus on the crane from the line. This switch is equipped with lock-out clips. Two single-pole circuit breaker contactors, one overload relay in the main circuit, one overload relay in one leg of each motor circuit, and no voltage relay control circuit fuses and a push button for resetting main circuit breakers are mounted on this panel. In this connection there is furnished an emergency switch, located within easy reach of the operator, by means of which he can stop all motions on the crane in case of emergency.

The operator's cab is located on the rotating boom at one side of the tower, giving the operator the best view of his work at all times.

Machinery House

The machinery house is located at the rear of the rotating boom and carries a runway for a hand operated crane. Special doors are provided at the rear of the house, opened and closed from the inside and so arranged that the hand operated crane can travel through them. The runway extends to the rear of the house a sufficient distance to permit of the raising or lowering of any part of the different mechanical units from the ground.

This mammoth crane was shipped by the Wellman-Seaver-Morgan Company in March, 1921, and put in operation at the south yard of the New York Shipbuilding Corporation in the summer of 1921. The total weight of the crane is 825 tons and of the structural material 625 tons.

Battleship Maryland, Recently Commissioned Flagship of the Atlantic Fleet

The electrically propelled battleship *Maryland* was built by the Newport News Shipbuilding & Dry Dock Company. The electrical equipment was manufactured by the General Electric Company. The main particulars are: Length, 624 feet; beam, 97 feet 6 inches; draft, 30 feet 6 inches; displacement, 32,600 tons; shaft horsepower, 28,000; speed, 21 knots; main battery, eight 16-inch guns; secondary battery, fourteen 5-inch guns.

The Economic Efficiency of Merchant Ships*

Analytic Methods Show How Effect of Factors Entering Into Final Efficiency Can Be Accurately Assessed and the Results Applied to the Design and Management of Ships

By John Tutin

A MERCHANT ship is primarily designed, constructed and placed on service for the transport of the maximum amount of freight-earning cargo at a minimum of expense, and hence with maximum return to the owner on his outlay. At the same time it must be borne in mind that since there can be no dividend, if the vessel capsizes or a crew cannot be persuaded to man her, the complete test of a merchant vessel should be made on the following lines:

(1) Profit earning capacity.
(2) Safety and comfort of crew, and passengers, if any. (Governing factors are: Board of Trade regulations, together with metacentric height, reserve of buoyancy, factor of subdivision, capacity of boats, period of roll, etc.).
(3) Strength of the structure (as determined by the vessel's classification).
(4) Resistance to propulsion.

These four divisions are all interdependent and frequently conflicting, the underlying idea in design being to obtain a vessel of such proportions and characteristics as to give maximum potential profits. Divisions 2, 3 and 4 have hitherto received by far the larger share of investigation, as a glance at the list of papers contributed to this institution will show. The profit earning capacity (division 1) measures the economic efficiency as indicated by profit per pound of capital per annum, and has only been approached from the technical standpoint within the last two or three years, Mr. John Anderson, Mr. Alexander Urwin, Messrs. Baker and Kent and Professor Scribanti having contributed important work on this aspect of the question.† The subject, however, has by no means been exhausted.

Let us consider the derivation of an expression for efficiency (E) as indicated by the potential profit. We may write:

$$E = \frac{\text{Freight earnings per annum} - \text{charges per annum}}{\text{Capital invested}} \times 100 \ldots (1)$$

This equation is absolute, and no assumptions are necessary. We are in no such happy position when we begin to develop the equation thus:

$$E = \frac{36{,}500\,V\,[(f-t)\,C - x\,T - q\,k\,l\,\Delta^{2/3}\,L\,V^2]}{(L + n_L . V)\,P} - 100\,y \ldots (2)$$

which is Mr. Baker's formula expressed as a "percent per annum," where
C = cargo deadweight in tons,
T = net tonnage,
Δ = displacement in tons,
P = first cost in £,
V = sea speed in nautical miles *per day*,
f = freight rate in £ per ton,
t = sum of brokerage, management, loading, discharge, etc., in £ per ton,
x = tonnage dues in £ per ton for complete journey,
l = a factor given by I.H.P. = $l\,\Delta^{2/3}\,V^3$,
q = cost of fuel in £ per ton,
k = tons of coal per day per I.H.P.,
y P = sum of insurance, repairs, wages, depreciation in £,
L = length of voyage in miles,
n_L = number of days in port for loading, discharging, etc.

Referring to the formula, we see that:

$(f-t)\,C$ represents the earnings per voyage in respect of cargo carried.
$x\,T$ represents the port dues per voyage.
$q\,k\,l\,\Delta^{2/3}\,L\,V^2$ measures the cost of the fuel consumed per voyage.
$\dfrac{365\,V}{L + n_L\,V}$ is the number of voyages made in the year.

It will be noticed that the assumption is made that I.H.P. is proportional to $\Delta^{2/3}\,V^3$. This will only hold approximately for speeds below the limiting economical speed.

Further, C is defined as "cargo deadweight," and will vary therefore with V and L for the same ship, owing to variation in bunker weight. It would be convenient for purposes of differentiation to have C a constant quantity for the same ship. Let us therefore write, assuming a deadweight carrying vessel: C′ = load displacement — (light weight + stores). A slight error will still be present owing to the fact that stores will vary with V and L. We must now increase the cost of fuel by debiting it with the gross loss in freights due to the carriage of fuel. Further, it would be inaccurate to assume that just sufficient coal is carried to enable the vessel to reach her destination. We must allow a reasonable margin in case of emergency. Let this factor in respect of reserve coal be r (a working value is about 4/3), and note that normally the additional coal is not necessarily consumed, but is nevertheless carried at the expense of cargo.

Finally, there is the personal element and danger of the vessel not being continuously supplied with cargoes. Let us assume a factor ϕ to cover these and other contingencies. This factor will represent the proportion of her total time during which the vessel is actively employed, and for purposes of comparison may be taken as unity.

Applying these corrections, the formula may now be written:

$$E = \phi\,\frac{36{,}500\,V\,[(f-t)\,C' - x\,T - (q + r\,f - r\,t)\,k\,l\,\Delta^{2/3}\,L\,V^2]}{(L + n_L\,V)\,P} - 100\,y \ldots (3)$$

The expression is now in a comparatively general form, and it may be claimed for this process of synthesis that practically every element of variation is accounted for, thus:

L, n_L, x represent respectively the effect of route, port facilities and port charges.
k characterizes the type of engines.
l takes account of form $\left(\dfrac{1}{l} \propto \text{Admiralty coefficient}\right)$.
y is governed by the current rates of wages, etc.
r will indicate roughly the weather conditions prevailing on the particular route and the extent to which the vessel uses her own cargo-handling appliances.
ϕ will take into account the efficiency of the captain and managers, and the state of the freight market.

The important point to notice in this new expression is that the true cost of fuel is now $(q + rf - rt)\,k\,l\,\Delta^{2/3}\,L\,V^2$, whence it is clear that the virtual price of fuel is

$$q' = [q + r\,(f-t)] \text{ per ton} \ldots\ldots (4)$$

For example, with the nominal price of coal, say, 20 shill-

*Paper read at sixty-third session of the Institution of Naval Architects, London, April, 1922.

ings, with a virtual freight rate $(f - t)$ of 20 shillings, reserve coal factor 4/3, the virtual price of fuel works out at $q' = 46$ shillings 8 pence per ton.

A similar expression for virtual price of fuel in a bulk cargo carrier is:

$$q' = q + \frac{r\rho'}{\rho}(f - t) \ldots\ldots\ldots\ldots (5)$$

where ρ' is fuel density and ρ is cargo density (in cubic feet per ton).

Where fuel is carried in the double bottom in such a ship the virtual (and nominal) price is simply q.

In connection with equations (3), (4) and (5) the following points should be emphasized:

(1) Cost of fuel is dependent on the reserve coal carried and the freight rate, and hence—

(2) The importance of reducing r as much as possible, consistent with the possibility of a stormy passage.

A mathematical shipowner might get excellent results from the theory of probability in determining the best r for a given voyage.

(3) The value of r for coasting vessels, cross-channel steamers, and smaller craft generally can and should be made larger than for ocean steamers.

(*a*) Because f is smaller, and hence the relative importance of r is diminished.

(*b*) Because on a short voyage the probability of rough weather in relation to the number of days at sea is increased.

(4) The virtual price of fuel per ton is in general less for bulk cargo than for deadweight.

When $\frac{\rho'}{\rho}$ is unity the fuel costs are equal, but since coal stows at about 45 cubic feet per ton, and the limiting density for "bulk" cargo, $\frac{\text{bale capacity}}{\text{deadweight}}$, may be taken at about 55, we see that for the same virtual freight rate the virtual price of fuel is materially less.

(5) Note from equation (3) that total fuel consumption on a given voyage is proportional to V^2, and that, given a vessel with bunker capacity for L miles at V knots, her trading radius can be very considerably increased by reducing V to some smaller speed, say v.

The radius is in fact increased in the ratio $\left(\frac{V}{v}\right)$, and this without materially affecting profits (see later).

When cargoes are scarce this fact would appear to be of some importance, since it means greater scope for a vessel with restricted bunker capacity; but the use which could be made of this would depend of course on the flexibility of the main engines.

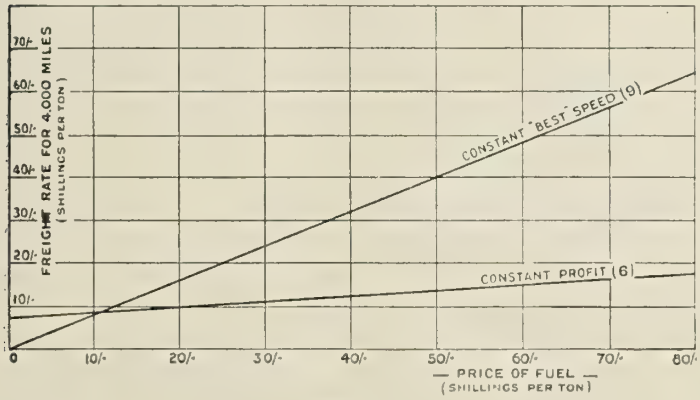

Fig. 1

These curves are drawn for assumed initial conditions:

$$f_0 = 10\text{s.}; \qquad q_0 = 12\text{s. 6d.}$$

and represent approximate values of freight rate and fuel price in order that—

(*a*) The "best" speed, which was initially the actual service speed, should remain constant.

(*b*) The initial efficiency or profit should remain constant.

N. B.—The ratio F/C required for curve (*b*) is taken for a 410-foot vessel (see Appendix).

Referring back to equation (3), we note that for a given ship designed for and trading on a given route, initially under external conditions specified by

$$f_0,\ q_0,\ \phi,\ x,\ y,$$

and making the reasonable assumption that changes in these quantities are confined to f_0 and q_0, the freight rate and fuel price, we can derive an instructive relation between these two factors if the owner's initial profit is to be maintained. Clearly this condition is expressed by:

$$fC' - (q + rf)\, k\, l\, \triangle^{2/3}\, V^2\, L = \text{a constant K}$$

And since $(k\ l\ \triangle^{2/3}\ V^2\ L) = F$, the fuel consumption in tons for the voyage, also K being determined by the initial values f_0, q_0, we obtain the result:

$$\frac{f - f_0}{q - q_0} = \frac{F}{C} \ldots\ldots\ldots\ldots\ldots\ldots (6)$$

where $C = C' - r\,F$ = net cargo capacity.

We deduce from this that if the initial profit is to be maintained, a curve of freight rate on a base of fuel price (Fig. 1) must be a straight line (for the given voyage), or, in other words, the ratio of increase in freight rate $(f - f_0)$ to increase in fuel price $(q - q_0)$ should be constant $\left(= \frac{F}{C}\right)$

Now the question naturally arises, what speed, i.e., what value of V for a given vessel, will make E a maximum? But before differentiating let us investigate any assumptions which would be implicit to that operation—clearly they are that all quantities other than V are constant.

We note that we have made C' constant, or nearly so, the slight variation of C' with speed owing to reduced stores, etc., as V is increased being offset by the increase in machinery weight, unless indeed we premise machinery of such flexibility that it can cope efficiently with wide variations of power.

Further, although displacement $\triangle$ at the beginning of a voyage may be assumed constant, yet owing to the fact that total fuel consumption on the voyage will vary as V^2, the displacement at the end of voyage will be by no means constant; in other words, the higher the speed the less the final displacement will be. Thus, as V is increased the mean value of $\triangle$ for the voyage is reduced. The effect will be to increase somewhat the calculated best speed, and the increase on the theoretical result will be greater the longer the voyage.

Differentiating now with respect to V, and equating the result to zero, we arrive at the result:

$$q'\, kl\, \triangle^{2/3}\, V^3{}_B \left(\frac{3L}{V_B} + 2nL\right) = (f'\,C' - x\,T) \ldots\ldots (7)$$

which gives the best speed, V_B, in terms of quantities which can be measured, calculated, or assumed for a given vessel (for working, see Appendix). We note that the best speed is not affected by wages y and capital P, nor by the "activity factor" ϕ, while it is dependent on all the other quantities in the expression for E.

A simpler equation for V_B can be derived thus:

Let the estimated "virtual" cost of coal for the whole voyage at a given speed, V_0, be $q'\ kl\triangle^{2/3}\ V^2{}_0L = M_0$.

Then the best speed is given by:

$$\frac{M_0 V^3}{L\ V^2{}_0}\left(\frac{3L}{V_B} + 2nL\right) = (f'\ C' - xT) \ldots\ldots\ldots (8)$$

In practice the best method of determining the best speed for a proposed vessel of deadweight C' (*ex* stores), and for given conditions of the shipping industry, is to construct an Efficiency—Speed curve based on equation (3). Such a curve can be of considerable guidance in the choice of a suitable speed. A specimen curve is shown (Fig. 2) for a 410-foot vessel.

The designed speed should approximate to as closely as possible, without exceeding, the "best" speed under the prevailing conditions. Before the best speed is reached there is quite a wide range of almost equally profitable speeds, whereas when the best speed is exceeded returns will very rapidly diminish. Conservatism with regard to designed speed cannot be too highly recommended, since, if freight rates fall more rapidly than the price of fuel, the designed speed may actually become the best speed while a similar but faster vessel is running at a loss. Similarly, if there is a spurt in freights, the vessel while maintaining her designed speed will still be able to run at an efficiency only slightly less than her sister vessel.

Summarizing results so far, we have obtained an expression for E and have shown how freight rate should vary, with fuel price, if a given ship is to maintain her initial E.

We have also obtained an expression for the best speed for a given ship under given initial conditions. How should freight rate vary with fuel price, if this best speed is to remain constant? It is obvious that a given speed might be the "best" speed over quite large variations in freight rate provided fuel can be obtained at corresponding prices.

Referring to equation (7), the condition for constant V_B can be written:

$$\frac{\partial V_B}{\partial f'}\,\delta f + \frac{\partial V_B}{\partial q}\,\delta q = 0$$

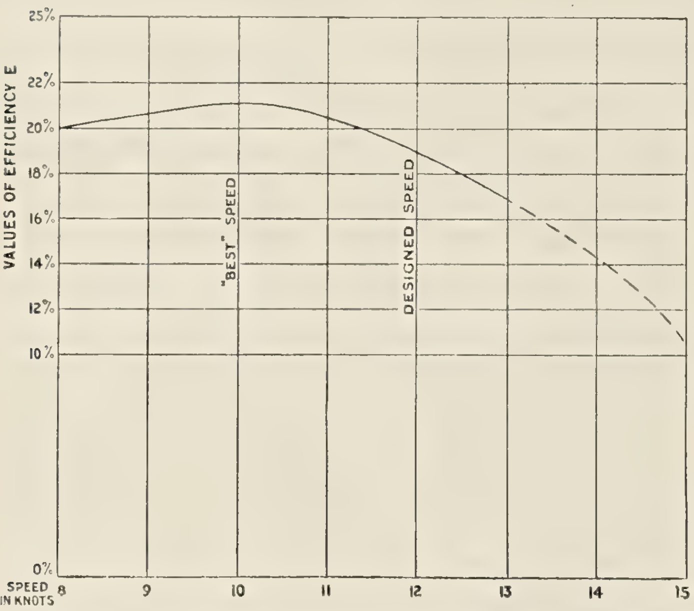

Fig. 2.—Efficiency-Speed Curve for a 410-Foot Vessel (For Details, See Appendix)

Length of voyage, 4,000 miles
(f) Freight rate, 10s.
(q) Price of coal, 12s. 6d.

The curve will be substantially the same for all values of f and q given by the formula:

$$\frac{f - f_0}{q - q_0} = \frac{f_0}{q_0}$$

$$\text{i. e. } \frac{f - 10\text{s.}}{q - 12\text{s. } 6\text{d.}} = 0.8$$

A direct calculation of the "best" speed under the same conditions, by formula (8), gave $V_B = 10.01$ knots.
i.e. the change in V_B due to changes δf and δq in f and q is zero; and on differentiating (see Appendix):

$$\frac{\delta f'}{\delta q} = \frac{f_0}{q_0}$$

(neglecting for our present purposes the effect of tonnage dues). A first approximation to the required relation is thus seen to be:

$$\frac{f - f_0}{q - q_0} = \frac{f_0}{q_0} \text{ (for constant "best" speed)} \ldots\ldots\ldots\ldots\ldots (9)$$

But an earlier formula gave:

$$\frac{f - f_0}{q - q_0} = \frac{F}{C} \text{ (for constant E)} \ldots\ldots\ldots\ldots\ldots (6)$$

In these formulæ, f_0, q_0 are initial and f, q are subsequent values of freight rate and fuel price, while F/C is the ratio $\frac{\text{Total fuel}}{\text{Cargo}}$.

An inspection of these formulæ reveals the fact that for a given increase in the cost of fuel, the increase in freight rate necessary to maintain the owner's profit is small compared with the increase which would be necessary in order that the normal service speed still remains the "best" speed. Since the normal tendency of the freight market will be to grant the shipowner more or less steady profits as indicated by equation (6) rather than (9), the necessity for a conservative designed speed becomes even more marked.

We may now proceed to the analysis of the efficiency formula and the determination of the influence which the various factors such as speed, displacement, tonnage, freight rate, length of voyage, etc., have on the final profit. In other words, we wish to measure the relative importance of these various factors in order that in a particular case we may see which factor or factors should receive most attention with view to maximum profits. Concentration on a factor in proportion to its relative importance should both in theory and in practice give improved results.

With this end in view, let us define "relative importance" of a given factor as "the percent change in the value of the expression for 1 percent change in the factor."

Thus, if $E = f\,(x_1, x_2, x_3 \ldots x_n \ldots)$, where f denotes "function of," then the relative importance of x_n is given by $\frac{\delta E}{E} \times 100$ for $\delta x_n = \frac{x}{100}$, and since $\delta E = \frac{\partial E}{\partial x_n}\,\delta x_n$, we have:

$$\text{R.I. of } x_n = \frac{\partial E}{\partial x_n} \cdot \frac{x_n}{E}$$

This method can be applied directly to the general expression for E [equation (3)], whence a formula for the relative importance of each factor can be derived. These formulæ and the corresponding numerical results for a 410-foot steamer are given in the Appendix. Having determined the relative importance of the factors in the final efficiency of the ship, quite a wide range of usefulness is opened out, since we may now

(1) Assess with a reasonable degree of accuracy the part each factor plays in the final efficiency, in relation to the other factors. From the sign (+ or —) of the relative importance we see whether the factor is "for" or "against"—whether efforts should be made to increase it or reduce it.

(2) Determine the resulting change in efficiency likely to accrue from any proposed changes in any factor or factors.

(3) In particular we can estimate closely whether ideas involving increased capital cost, and/or loss of deadweight, are worth adopting under current conditions.

If, for instance, the naval architect is considering the merits of a patent cargo-handling system, for which certain advantages over the normal type are claimed, he could make a rough estimate (see table on page 389).

(4) We can compare the merits of different voyages, routes or trades in a similar way, taking into account the freight rate offered, fuel costs at each end, port dues, etc.

(5) We can compare the efficiencies of two ships. Since E is so largely dependent on external factors, it is desirable that there should be some easily applied "test" of ships which is independent of these factors. By adopting a ratio method as indicated in the Appendix, a useful means of comparison is obtained.

Referring to the relative importance formulæ and numerical results given in the Appendix, it will be noticed that

while the formulæ given are only for the factors definitely entering into the efficiency formula, yet by means of the theorems enunciated in the Appendix the formula for almost any conceivable subsidiary factor can be derived. It must be borne in mind that theoretically a relative importance number only holds over a small range of variation in values owing to its being based on a partial differential coefficient. In almost all cases, however, except in that of speed, a reasonable degree of freedom may be taken in practice. The following notes on the Appendix results may be found useful.

Speed (1).—The relative importance of V is necessarily zero at the "best" speed, since $\frac{\partial E}{\partial V} = 0$, and above the best speed is negative and increases very rapidly. Below the best speed it is positive, but increases more slowly. See the E—V curve, Fig. 2.

Displacement (2).—This formula refers to changes of draft only, with consequent reduction in the weight of fuel consumed.

Estimated Effect on Factors: Factor	Percent	Relative Importance	(Product) Percent Increase in E	(Product) Percent Decrease in E
Time in port	— 10	— 0.573	5.73	—
Cargo handling expenses	— 10	— 1.4	14.00	—
First cost	5	— 1.733	—	8.66
Deadweight capacity	— 5	3.03	—	15.15
Total	—	—	19.73	23.81

First Cost (3), *Activity* (4), *and Number of Voyages per Annum* (21).—Necessarily of equal importance. First cost negative, ϕ and N positive.

Size (5).—The assumption is made that the size of the vessel is increased with proportional increases in $\triangle$, P, T, C. An interesting result is obtained, namely, that unless the vessel is being run at a loss increase of size will always mean increased efficiency, since when E is positive the relative importance of size is always positive. Since l diminishes with increase of size this effect is actually more pronounced.

M. Bertin (Assoc. Tech. Mar., 1913) shows, however, that there is a definite limit to increase of size, from structural considerations.

Deadweight (11).—As might have been anticipated, this is the most important factor. For example, under normal external conditions (A), a change of 1 percent in deadweight produced a change of no less than 3 percent in the efficiency. This illustrates the value of any means for reducing hull, machinery, equipment or fuel weights.

Freight Rate (8).—It might at first be thought that this should be of the same importance as deadweight, but f also occurs in the expression for the cost of fuel, and hence its importance is somewhat diminished.

Tonnage (12) *and Tonnage Dues* (16).—Necessarily of equal importance, and yet, judging by the numerical result, this importance is sometimes over-estimated.

Total Coal, Fuel Consumption and Form (13).—This result is interesting, since it shows that engine design and form are of equal importance; to be more precise, one may split up the factors l and k thus:

$$l = \frac{\text{I.H.P}}{\triangle^{2/3}\,V^3} \text{ where V = miles per day.}$$

$$\text{i.e. } \frac{1}{l} \propto \frac{\triangle^{2/3}\,V^3}{\text{E.H.P.}} \times \frac{\text{E.H.P.}}{\text{S.H.P.}} \times \frac{\text{S.H.P.}}{\text{I.H.P.}}$$

where

$$\frac{\triangle^{2/3}\,V^3}{\text{E.H.P.}} \text{ measures "form" efficiency}$$

and

$$\frac{\text{E.H.P.}}{\text{S.H.P.}} = \text{propeller efficiency}$$

= (screw efficiency in open) × (hull efficiency) × (relative rotative efficiency)*

and

$$\frac{\text{S.H.P.}}{\text{I.H.P.}} = \text{engine efficiency.}$$

Also

$$\frac{1}{k} \propto \text{(calorific value of fuel)} \times \text{(thermal efficiency of engines)},$$

and hence the product $k\,l$ is made up of the following component factors, each of equal numerical importance to k and l but of opposite sign (+):

$\frac{1}{kl}$ ∝ calorific value of fuel .... (*a*)
× thermal efficiency of engines .... (*b*)
× mechanical efficiency of engines .... (*c*)
× efficiency of thrust block and bearings .... (*d*)
× screw efficiency in open .... (*e*)
× relative rotative efficiency .... (*f*)
× hull efficiency .... (*g*)
× form efficiency .... (*h*)

The factors giving most scope for improvement would appear to be (*a*) (adopting liquid fuel); (*b*) (Diesel engines in place of steam); (*d*) (single collar thrust block); (*e*) (increased attention to propeller design).

In actual design it must be remembered that the factors which will best repay concentrated efforts towards improvement are those which afford the most scope for variation in association with their relative importance values; and in conclusion I submit that only by a study of the individual effect which each factor or group of factors has on the final efficiency can one hope to obtain clear ideas on what to make for in ship design.

APPENDIX I

RELATIVE IMPORTANCE FORMULÆ

General expression for efficiency:

$$E = \frac{\phi\, 36{,}500\, V\, [f'\, C' - x\, T - q'\, k\, l\, \triangle^{2/3}\, V^2\, L]}{(L + n_L\, V)\, P} - 100\, y$$

NOTE.

$f' = (f - t) =$ Virtual freight rate.
$q' = (q + r\,f - r\,t) =$ Virtual fuel price.
$k\,l\,\triangle^{2/3}\,V^2\,L = F =$ Total fuel consumption.

1. *Speed.*

$$\frac{\partial E}{\partial V} \cdot \frac{V}{E} = \frac{V}{E} \cdot \frac{36{,}500\,\phi}{P} \left\{ \frac{f'\,C'\,L - L\,x\,T - q'\,F\,(3\,L + 2\,V\,n_L)}{(n_L\,V + L)^2} \right\}$$

2. Displacement (for changes of draft only).

$$\frac{\partial E}{\partial \triangle} \cdot \frac{\triangle}{E} = \frac{-\triangle}{E} \cdot \frac{\phi}{P} \cdot \frac{36{,}500\,V}{L + n_L\,V} (\tfrac{2}{3} q'\,k\,l\,\triangle^{-1/3}\,V^2\,L)$$

3. *First Cost.*

$$\frac{\partial E}{\partial P} \cdot \frac{P}{E} = -\left(1 + \frac{100\,y}{E}\right)$$

4. *"Activity."*

$$\frac{\partial E}{\partial \phi} \cdot \frac{\phi}{E} = +\left(1 + \frac{100\,y}{E}\right)$$

5. *Displacement* (for changes of size with proportional changes in $\triangle$, P, T, C').

$$\frac{\partial E}{\partial \triangle} \cdot \frac{\triangle}{E} = \frac{\triangle}{E} \cdot \frac{36{,}500\,V\,\phi}{n_L\,V + L} \cdot \frac{1}{3}\,\frac{\triangle^{-4/3}}{a_3}\,q'\,k\,l\,L\,V^2 \begin{cases} C' = a_1\,\triangle \\ T = a_2\,\triangle \\ P = a_3\,\triangle \end{cases}$$

6. *Time in Port.*

$$\frac{\partial E}{\partial n_L} \cdot \frac{n_L}{E} = \frac{-n_L}{E} \cdot \frac{36{,}500\,V\,\phi}{P} [f'\,C' - x\,T - q'\,F] \frac{V}{(n_L\,V + L)^2}$$

7. *Wages, Depreciation, etc.*

$$\frac{\partial E}{\partial y} \cdot \frac{y}{E} = \frac{-100\,y}{E}$$

8. *Freight Rate.*

$$\frac{\partial E}{\partial f} \cdot \frac{f}{E} = \frac{f}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L\,V + L)\,P} (C' - r\,F)$$

9. *Length of Voyage.*

$$\frac{\partial E}{\partial L} \cdot \frac{L}{E} = \frac{L}{E} \cdot \frac{36{,}500\,V\,\phi}{P} \frac{\left\{ (n_L\,V + L)\,\frac{q'\,F}{L} + (f'\,C' - x\,T - q'\,F) \right\}}{(n_L\,V + L)^2}$$

*See G. S. Baker, *Ship Form, Resistance and Screw Propulsion*, page 170.

10. *Fuel Price.*

$$\frac{\partial E}{\partial q} \cdot \frac{q}{E} = \frac{-q}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot F$$

11. *Deadweight.*

$$\frac{\partial E}{\partial C'} \cdot \frac{C'}{E} = \frac{C'}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot f'$$

12. *Tonnage* (*Net*).

$$\frac{\partial E}{\partial T} \cdot \frac{T}{E} = \frac{-T}{E} \cdot \frac{36{,}500\,V\,\phi}{(L + n_L V)\,P} \cdot x$$

13. *Fuel Consumption* (per I.H.P.-hour).

$$\frac{\partial E}{\partial k} \cdot \frac{k}{E} = \frac{-k}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot \frac{q'\,F}{k}$$

14. *Admiralty Coefficient.*

$$\frac{\partial E}{\partial l} \cdot \frac{l}{E} = \frac{l}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot \frac{q'\,F}{l}$$

These are therefore of equal importance, since k and l cancel.

15. *Reserve Coal.*

$$\frac{\partial E}{\partial r} \cdot \frac{r}{E} = \frac{-r}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot f'\,F$$

16. *Tonnage Dues.*

$$\frac{\partial E}{\partial x} \cdot \frac{x}{E} = \frac{-x}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P} \cdot T$$

17. *Total Freight Earnings.*

$$\frac{\partial E}{\partial (f'\,C')} \cdot \frac{f'\,C'}{E} = \frac{f'\,C'}{E} \cdot \frac{36{,}500\,V\,\phi}{(L + n_L V)\,P}$$

18. *Total Tonnage Dues.*

$$\frac{\partial E}{\partial (x\,T)} \cdot \frac{x\,T}{E} = \frac{-x\,T}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P}$$

19. *Total Fuel Costs.*

$$\frac{\partial E}{\partial (q'\,F)} \cdot \frac{q'\,F}{E} = \frac{-q'\,F}{E} \cdot \frac{36{,}500\,V\,\phi}{(n_L V + L)\,P}$$

20. *Number of Voyages per Annum.*

$$\frac{\partial E}{\partial N} \cdot \frac{N}{E} = \left(1 + \frac{100\,y}{E}\right)$$

21. *Length of Voyage* (with proportional variations in freight rate).

$$\frac{\partial E}{\partial L} \cdot \frac{L}{E} = I_L + I_f \quad \begin{pmatrix} I_L = \text{R.I. of L, } f \text{ constant} \\ I_f = \text{R.I. of } f\text{, L constant} \end{pmatrix}$$

Theorem 1.—If x_n is a term in an expression (E) and of relative importance α, and z_n is a term in the expression x_n and of relative importance therein β, then the relative importance (ρ) of z_n in the expression E is given by:

$$\rho = \alpha\,\beta$$

Theorem 2.—If x_n, x_m are terms in an expression (E) and of relative importance α, α_1, and z_n is a term in both x_n, x_m and of relative importance therein of β, β_1, then the relative importance (ρ_1) of z_n in the expression is given by:

$$\rho_1 = \alpha\,\beta + \alpha_1\,\beta_1$$

Numerical Results.

The vessel considered is the third vessel in Mr. Anderson's series of five. Calculations for this vessel have also been made by Mr. Baker ("Best" Speed) and by Professor Scribanti (Depreciation), in addition to Mr. Anderson.

Deadweight	8,260 tons	Length of voyage (L)	4,000 miles
Deadweight (C')	8,110 tons	Freight rate (f)	10s per ton
Displacement (△)	11,520 tons	Cargo handling (t)	3s. 6d. per ton
Net tonnage (T)	3,120 tons	Tonnage dues (x)	1s. 3d. per ton
Sea speed (V)	288 miles/day 12 knots	Price of coal (q)	12s. 6d. per ton
Time in port (n_L)	6.8 days	Wages depreciation (y P)	1/7 P
First cost (P)	66,800 pounds	"Activity" (ϕ)	0.85
Total coal consumed (F)	901 tons	Total coal carried (r F)	1,081 tons (r = 1.2)

Relative importance factors are worked out for the following three sets of conditions:

f = 10s. q = 12s. 6d. E = 19.5 percent	A. Approximately "normal" relations between f and q. The designed speed (12 knots) is, however, somewhat in excess of the "best" speed, but in view of the mean displacement effect the difference is not so great as it would seem.
f = 23s. 6d. q = 12s. 6d. E = 126 percent	B. Abnormally high freight rate in relation to the fuel prices. Twelve knots is very nearly the "best" speed.
f = 10s. q = 20s. E = 12.2 percent	C. Abnormally low freight rate, the vessel is now running at a most uneconomical speed. Since under these conditions ϕ is probably much less than 0.85, the ship will presumably be laid up.

Formula		Relative Importance Factors A	B	C
11	Deadweight	+3.03	+1.44	+4.85
8	Freight rate	+2.62	+1.24	+4.22
3	First cost	—1.73	—1.11	—1.17
4	Activity	+1.73	+1.11	+1.17
—	Cargo handling costs	—1.43	—0.221	—2.29
13	Total coal consumption	—1.05	—0.291	—2.30
13	Form	—1.05	—0.291	—2.30
13	Fuel per I.H.P.-hour	—1.05	—0.291	—2.30
7	Wages, etc.	—0.733	—0.113	—1.18
2	Displacement	—0.700	—0.194	—1.54
10	Price of fuel	—0.647	—0.103	—1.67
6	Time in port	—0.573	—0.364	—0.714
15	Reserve coal	—0.403	—0.191	—0.645
5	Size of vessel	+0.354	+0.098	+0.775
1	Speed	—0.313	+0.053	—1.036
12	Tonnage	—0.23	—0.035	—0.368
16	Tonnage dues	—0.23	—0.035	—0.368
9	Length of voyage	—0.22	—0.103	—0.375
	Efficiency	19.5 perc't.	126.7 percent	12.2 p. ct.
	"Best" Speed (Knots)	10.01	13.2	8.0

The relative importance results may be assumed to hold approximately for any other values of f and q which are in proportion to the above, as per formula (6).

The variation in the order of magnitude under different external conditions shows that the details of design which should receive most attention will vary with the prevailing conditions of shipping.

Ratio Method

The merits of two ships can be compared as below, the advantage of the method being that while it is based on the results of the E formula, it is more readily performed, and at the same time a weak point in the vessel's efficiency can be at once detected; the relative importance values should, of course, be normal.

Ratio (Constant D.W. Denominator)	Values of Ratio: "Standard" or Basis Vessel	Values of Ratio: "Test" Vessel	Percent Difference from "Standard": +	Percent Difference from "Standard": —	Relative Importance Factor	Effective Differences: +	Effective Differences: —

†This ratio equals speed in knots.
‡This factor estimates the influence of speed on the rate of earning profits without reference to its effect on fuel bill.

N. B.—Other ratios can be introduced: $\frac{\text{Machinery weight}}{\text{Deadweight}}$, $\frac{\text{Hull weight}}{\text{Deadweight}}$, $\frac{\text{Water ballast}}{\text{Deadweight}}$, etc.

Derivation of Formula (2)

1. Developing formula (1) we have:

$$E = \frac{\text{Earnings per voyage} - \text{Charges per voyage}}{\text{Capital}} \times \text{Number of voyages} \times 100$$

Earnings per voyage can be written as $(f - t)$ C.
Charges per voyage may be split up thus:

(*a*) Tonnage dues: x T.

(*b*) Fuel cost: q (weight of fuel consumed) $= k\,l\,\triangle^{2/3}\,V^3) \times \frac{L}{V}$

(*c*) Annual charges: Wages, depreciation, etc., totalling y P, and as a percentage of P: 100 y.

$$\text{Number of voyages} = \frac{365}{\text{Number of days for complete voyage}} = \frac{365}{n_S + n_L}$$

where n_S = time at sea, n_L = time in port.
But

$$n_S = \frac{L}{V},\quad (n_S + n_L) = \frac{n_L V + L}{V}$$

$$\therefore \text{number of voyages} = \frac{365\,V}{n_L V + L}$$

and thus formula (2) is derived as:

$$E = \frac{365\,V}{n_L V + L}\,[(f - t)\,C - x\,T - q\,k\,l\,\triangle^{2/3}\,V^2\,L] \times \frac{100}{P} - 100\,y$$

2. The fuel of total weight $r\,k\,l\,\triangle^{2/3}\,V^2\,L$ is carried at the expense of cargo, and thus the loss in freight earnings is $(f - t)\,r\,k\,l\,\triangle^{2/3}\,V^2\,L$ pounds. The fuel consumption, however, is only $k\,l\,\triangle^{2/3}\,V^2\,L$ and price q pounds per ton.

Net cost of fuel is therefore:

$$q\,k\,l\,\triangle^{2/3}\,V^2\,L + (f - t)\,r\,.\,k\,l\,\triangle^{2/3}\,V^2\,L \text{ pounds} = (q + r\,f - r\,t)\,k\,l\,\triangle^{2/3}\,V^2\,L \text{ pounds.}$$

Whence also virtual price of fuel consumed:

$$q' = (q + r\,f - r\,t) \text{ pounds per ton.}$$

3. Differentiating equation (3) for "best" speed, we have:

$$\frac{\partial E}{\partial V} = \frac{\phi\,.\,36{,}500}{P\,(n_L V + L)^2}\,[(n_L V + L)\,(f'\,C' - x\,T - 3\,q'\,F) - n_L\,V$$

Cement and Concrete for Shipbuilding Purposes—II

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

THE Tentative Standard Specifications determine the consistency of the mix by a slump test in the manner described in the "Tentative Specifications for Workability of Concrete for Concrete Pavements" of the American Society for Testing Materials, D62-20T. These specifications measure the consistency by the amount of slump or loss in height of a freshly mixed column of concrete in the form of a truncated cone 12 inches high, 8 inches in diameter at the bottom and 4 inches in diameter at the top. The Tentative Standard Specifications leave the amount of slump to the determination of the engineer on the operation, but fix a maximum slump of 6 inches for reinforced concrete for thin vertical sections and columns, and 8 inches for thin confined horizontal sections. The Shipping Board specifications require the water to be limited to the minimum that will permit the concrete to be worked into every part of the form, to embed the reinforcing completely and to produce a dense and watertight concrete. They adopted a slump test which consisted of filling a hollow cylindrical mold 6 inches in diameter and 12 inches long with the concrete to be used, setting this on end on a plate of glass or finished metal immediately after filling it, and withdrawing the mold with a slow vertical pull. They specified that under no circumstances should any concrete be used in the construction of the vessel that showed by this test a slump or drop exceeding 75 percent of the original 12-inch height of the concrete cylinder.

Proportions of Ingredients in Cement and Concrete

The Portland cement, fine aggregate and coarse aggregate in concrete should be such as to produce a material of the necessary plasticity that will have the desired quality and strength. The workability as determined by the slump test and the compressive strength at 28 days age are the principal factors. A very usual construction mixture is one part by volume of Portland cement to two parts of fine aggregate and four parts of coarse aggregate. A bag of Portland cement weighs 94 pounds and is considered to be one cubic foot.

The Tentative Standard Specifications include tables which for various sizes of coarse aggregate and fine aggregate give the proportions of the ingredients that at certain consistencies may be expected to produce concrete of the compressive strength at 28 days, for which each table is made up. These specifications, however, require that concrete in sea water or exposed directly along the sea coast shall contain not less than 1½ barrels (6 bags) of Portland cement per cubic yard in place; that concrete from 2 feet below low water to 2 feet above high water, or from a plane below to a plane above wave action, shall be made of a mixture containing not less than 1¾ barrels (7 bags) of Portland cement per cubic yard in place; and that slag, broken brick, soft limestone, soft sandstone or other porous or weak aggregates shall not be used.

Concrete below the ground line in alkali soils or water is required by the Tentative Standard Specifications to contain not less than 1¾ barrels (7 bags) of Portland cement per cubic yard in place.

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

The specified Shipping Board mixes were as follows:

Class A—1: 2/3: 1⅓
- 1 bag of Portland Cement
- 2/3 cubic feet of fine aggregate
- 1⅓ cubic feet of coarse aggregate

Class C—1: 2
- 1 bag of Portland Cement
- 2 cubic feet of fine aggregate.

The Class C mixture, which is cement or cement mortar rather than concrete, was allowed for the bilges and other equally difficult curved and warped surfaces where specifically authorized. All other structural concrete was specified to be Class A. In some cases the mix was made 1:⅚:1⅙.

Where joints have to be made in watertight construction on account of not being able to finish the work in one continuous operation, a heavy coating of neat Portland cement is required.

The mixes of cement for deck covering have been dealt with under that head, being generally 1:2. Classification society requirements for the protective cement coatings specified by them call for proportions of about 1:2.

Curing Concrete

The curing of concrete may be defined as the prevention of premature drying and it is essential to the development of high resistance to abrasion.

The Shipping Board required that for a period of at least two weeks after the forms were removed from any part of the concrete vessels the surface should be wetted down by sprinkling at least four times a day. In case of excessive heat they extended this to sprinkling the forms before removal after the concrete had been placed in them.

Materials for Waterproofing Concrete

As can be readily appreciated, the concrete used in concrete ship construction should be made as waterproof as possible, in order to keep water from passing through the relatively thin walls, in order to protect the steel reinforcing from corrosion and consequent destruction and in order to protect the concrete itself from possible action of certain elements in the sea water. Much can be done in this direction by careful grading and mixture of the solid materials and the avoidance of an excessive amount of water, because the formation of the colloids previously referred to gives to concrete a considerable degree of watertightness. The density and watertightness can also be increased by vibrating the forms while the concrete is being poured and skillful handling generally. Special waterproofing is, however, advisable for the main structural parts of a vessel and those that are exposed to salt water. Materials for this purpose are of two general classes—integral waterproofers and surface waterproofers.

Integral Waterproofing

Integral waterproofing materials are also of two general classes—those which are primarily designed to increase the density of the concrete and those which are primarily designed to prevent water from wetting the surfaces of the pores, thus destroying their ability to draw water in. It

would seem to be a very difficult undertaking to find a material that can be added to a concrete mixture which will fill up pores caused by the evaporation of the water in excess of that necessary to hydrate or set the cement, although materials which will increase the fatness of the mix and make it easier to compact will decrease the porosity. It is not so difficult, however, to find a material that will in a great measure make the concrete water repellent.

It is well known that a liquid is drawn up on any surface which it wets by what is called capillary attraction and that, if this surface is the inside surface of a tube, it will be drawn up a considerable distance. If the liquid does not wet the surface, it is actually depressed at the surface and in such cases a very small tube offers considerable resistance to the ingress of the liquid. The porosity of concrete is of the nature of very small tubes or ducts. A water repellent material that will coat the surfaces of the pores should therefore be of value as an integral waterproofer.

The aims sought by the manufacturers of integral waterproofing compounds in whole or in part are:

Maximum permanent repellency.

Constituents that will develop colloids, and thus as far as possible fill up the pores.

A material that can be uniformly distributed through the concrete by means of the water.

A material that will not react with the concrete materials and injuriously affect the compressive and tensile strength.

A material that will, like soap used in washing, reduce the surface tension of the mixing water, or lubricate the mix, and thus make the concrete more dense.

Absence of inert or inactive elements.

Freedom from any element soluble in water after the work is completed.

At least one of the manufacturers of integral waterproofing claims to have a compound which fulfills all of the above desiderata. It is in the form of a paste containing a combination of aluminum as an insoluble soap with palmitic or stearic acids, and also other elements. Other materials used by different manufacturers of integral waterproofing are sodium soap, stearate of lime, glue solutions, water glass and various oils.

Integral waterproofers that are largely or entirely pure silica are on the market and claim to increase the imperviousness of concrete by combining with the free lime which usually develops to a certain extent, thus fixing it and making it a permanent constituent of the concrete, whereas it would otherwise gradually dissolve out. Kieseguhr or diatomaceous earth and a product made from the pulverized shells of small sea animals are of this nature. Such materials were used on some of the Shipping Board's tankers in the nature of a lubricator, to fatten the concrete and thus make it more dense. They also aided in the density by being very finely ground. An efficient waterproofer of this character that does not introduce harmful results in other directions is also of value in preventing the destruction of surface coatings by the free lime. On some concrete ships exterior coatings containing oil have been attacked and destroyed by alkali salts brought to the surface, simply by testing tanks with water on the inside.

Builders of the concrete ship *Faith,* which was completed in San Francisco in 1918, are said to have made use of a material which relied on colloidal properties to plug up the pores.

Integral waterproofers should be thoroughly tested as to their value and their effect on the concrete. Some of them tested for the Shipping Board by the Bureau of Standards were found to be of little or no value in reducing the absorption of water, or were found to reduce materially the compressive strength of the concrete. The Tentative Standard Specifications state definitely that integral waterproofing compounds shall not be used, thus taking the stand that they are necessarily valueless or harmful in other directions, which is not the case.

Surface Waterproofing

Surface waterproofing is the method that has to date been most generally relied upon and a great variety of paints, oils and other compounds for this purpose are on the market. A coating of this kind besides being waterproof should be sufficiently elastic to remain intact, if fine cracks develop in the concrete, and should adhere well to concrete. If the surface is to be later coated with oil paint, the waterproofer should be of a nature that such paints will adhere to.

There are a number of proprietary mastic compounds for waterproofing using various kinds of tar and pitch, asphalt and elaterite, generally with asbestos fiber. They, however, will not penetrate the concrete. It has been found that short fibered asbestos is a valuable constituent of such waterproofing coatings, in assisting them to remain intact over the fine cracks which develop in the surface of the concrete, and that its quality has quite a bearing on the smoothness, consistency and covering power of the paint. The Bureau of Standards recommended that a sample of the asbestos to be used should be submitted by the paint manufacturer and that specifications should require it to be ground into the paint by passing at least twice through the grinders.

There are also compounds using paraffin, aluminium stearate, ammonia soap, etc. Oil paints will not adhere to a concrete surface waterproofed with paraffin.

Linseed oil, raw tung oil (China wood oil) and rosin oil penetrate concrete rapidly. The first mentioned is the most valuable as surfaces treated with this oil take coatings of oil paint better than when treated with the other oils. The oil first absorbed is undoubtedly converted into the lime soap of the oil by saponification with the free lime in the concrete. This is a water repellent material and has therefore waterproofing properties. Subsequent applications of the oil oxidize and form an elastic film which has good waterproofing properties, and this film is under the surface, where it is most desirable that it should be.

Perilla oil is another gumming oil which cures by oxidation rather than by evaporation of volatile matter and has high saponification value. It has been found by test to be a valuable surface waterproofer, and to penetrate concrete to a depth of 3/16 inch or more and make it repellent to the water in the manner explained under the head of integral waterproofing, thus partaking of the nature of such waterproofers. It has been found to be more resistant to the action of caustic lime than linseed oil and to furnish a good bond for succeeding coats of paint or varnish. To obtain best results such a coating should be applied as a saturated coat, i.e., in addition to the first general cover coat; subsequent touching-up coats should be applied to portions of the surface where the larger local porosity allows a quicker penetration. The saturation, however, should not be carried to the point where a film of the oil is left on the concrete surface. The oil should be received fresh from the manufacturer and stored in airtight containers until used. When exposed to the air in bulk it becomes somewhat fatty in time and when applied to the concrete gives a slow drying outer film. It may be expected to have in the long run a more waterproofing effect than spar varnish, since the original protective film of varnish, which does not penetrate, seems to soften and loosen with age.

Spar varnish makes a good waterproof coating and, when white lead pigment is ground into it in proportions of 40 to 45 percent of the pigment with 55 to 60 percent of varnish, a very serviceable, elastic waterproof paint with good body is formed. Such a paint is used for coating the pontoons of naval seaplanes. It is the gray enamel hereinafter referred to.

The Shipping Board tried out a process of coating the surface of the concrete with copper in the form of a metal spray. They found that the metal went into all of the nooks and crannies of the surface no matter how rough the surface

was; but that the particles of copper were somewhat oxidized and the coating was porous. They found also that the apparatus as made at that time would not stand up under continuous work and that it was therefore not satisfactory for large operations.

After careful research and the testing of a variety of special materials, some of which have nct been referred to here, the Shipping Board adopted spar varnish for the outside of the hull and all surfaces in cargo holds and engine and boiler rooms, and applied it on some of the ships. The results obtained on the outside of the hulls were unsatisfactory, due largely to the action of the lime in the concrete on the linseed oil in the varnish; and the results obtained on the inside of the hull were unsatisfactory owing to the practical impossibility of making it dry thoroughly in such spaces.

The coatings specified by them for the interior surfaces of water ballast and fresh water tanks and the shaft tunnel and all interior hull surfaces where water might accumulate, except cargo spaces, were a bituminous primer, C.S.9, and coating C.S.10, in accordance with the following specifications.

Bituminous Hull Paint—C.S.9

This shall consist of an asphalt base thinned with petroleum distillate. The asphalt base shall meet the following requirements:

Penetration at 77 degrees F. not more than 12 nor less than 8.

Melting point not less than 205 degrees F. nor more than 220 degrees F. (ring and ball method).

Soluble in cold carbon bisulphide not less than 99.5 percent.

Organic matter insoluble in carbon bisulphide not more than 0.2 percent.

Ash, not more than 0.3 percent.

A thin flake of material shall be capable of slow bending without breaking.

The completed bituminous hull paint shall contain approximately 60 percent of the thinner and it shall, when applied with a brush to a glass plate, dry at least to a tacky state in not more than one hour and shall be free from tackiness in not more than five hours. Also it shall be such that it may be applied satisfactorily while cold by means of a compressed air paint spraying device when worked with a pressure of 60 to 70 pounds per square inch.

Bituminous Thickened Hull Paint—C.S. 10

This paint shall be made by adding and grinding into the bituminous hull paint (Specification C.S. 9), approximately fifteen percent of extremely finely powdered silicious matter such as aluminum silicate, magnesium silicate, or a mixture of these, and approximately fifteen percent of short fibered inert mineral matter such as asbestos. No slaked lime nor calcium carbonate shall be used.

The thickened paint shall be applied with a brush and shall be such that a relatively thick paint film, which shall dry readily, will be obtained. This paint, therefore, shall have satisfactory brushing and spreading qualities.

After about two years of test and experimentation these were superseded by the following specifications C.S.37 and C.S.38, which were also extended to replace the varnish on the outside of the hulls and in the dry cargo holds.

Bituminous Primer—C.S. 37

This shall consist of a mixture of 60 percent base and 40 percent mineral spirits.

The base shall be a mixture of:

"Texaco 34"	90 percent
Rubrax grade "B"	10 percent

The Texaco 34 asphalt shall meet the following requirements:

Melting point (ring and ball method)	140 degrees F.
Penetration	45 degrees F.
Ductility	86 degrees F.

The Rubrax grade "B" asphalt shall meet the following requirements:

Melting point (ring and ball method)	243 degrees F.
Penetration	7 degrees F.
Ductility	0 degrees F.
Solubility in CS_2	99.9 percent

Bituminous Hull Paint—C.S. 38

This shall consist of a mixture of 50 percent base, 16.6 percent fibrous asbestos filler and 33.4 percent mineral spirits.

The base shall be a mixture of:

"Texaco 34"	90 percent
Rubrax grade "B"	10 percent

The asphalt requirements are as before mentioned.

The volatile mineral spirits in both specifications shall be a hydrocarbon distillate, water white, neutral clear and free from water. It shall have no darkening effect when mixed with basic carbonate white lead.

When 10 cubic centimeters are put in a glass crystallizing dish 2½ inches in diameter, and placed on a steam bath for 2½ hours, the residue shall not exceed .03 grams.

When tested according to the standard tests for paint thinners other than turpentine, prescribed by the American Society for Testing Materials, the flash point shall be not less than 29 degrees C. (85 degrees F.), in a closed tester, and in the distillation test, the first drop shall issue from the condenser at a temperature not below 129 degrees C. (265 degrees F.) and 97 percent shall distill below 243 degrees C. (470 degrees F.).

Good rules for the application of such coatings are: Before painting, all surface dust should be removed with a soft bristle brush and the surface should be as dry as possible and free from all surface water. The first coat of the thin paint, thinned as suggested before, shall then be applied and after drying it shall be inspected for brown and uncoated spots. These should be re-coated with the thin paint. About thirty-six hours shall elapse between the application of the thin paint and the first coat of the thick paint. This depends entirely upon weather conditions. The second coat can be applied with the paint sticky but in such condition that when rubbed with the hand no paint shall be removed. After the application of the second coat the paint should be allowed to dry twenty-four hours. The third is then applied and at least forty-eight hours should elapse before putting in the blocking. It is suggested that before putting in the blocking it be liberally dusted with powdered soapstone. All cement patches shall be allowed to cure at least three days and preferably longer before coating.

A heated asphaltic cement coating with a priming coat of the same mixture thinned with benzine or gasoline to the consistency of paint and applied cold was proposed for and the writer understands used upon the barges built by the United States Railroad Administration for service between New York City and Buffalo. It was submitted to the Bureau of Standards with a view toward ascertaining if the elasticity or life of the asphalt would be affected by the volatile oil in the priming coat; and it was their opinion that such would not be the case. The priming coat was necessary because a heated asphaltic cement coating applied direct to concrete will peal off of it upon cooling. The formula as proposed consisted of 100 parts of Bermudex refined asphalt mixed with 11½ parts of Craig oil flux at a temperature of about 300 degrees Fahrenheit.

One of the West Coast builders of the Shipping Board's concrete tankers recommended for the outside of the hull an application of magnesium fluosilicate, then a coat of perilla oil to full saturation, followed by a coat of a plastic concrete paint manufactured by one of the varnish manufacturers applied with a trowel, the surface being subsequently squeegeed off, leaving the hull very smooth and every open air or bubble hole in the concrete filled with a hard material that water did not appear to affect in the least. This was to be covered with two coats of Elaterite. It is not known that any concrete ships have been coated in this manner. Tests made by the Shipping Board of the Elaterite alone were unsatisfactory.

The Tentative Standard Specifications state that membrane waterproofing, consisting of a coating reinforced by fabric, felt, or similar toughening material, shall be used in basements, pits, shaft tunnels, bridge floors, retaining walls and similar structures where an added waterproofing protection is desired.

(To be continued)

A Simple Chronograph for Launching Observations

By John P. Comstock

IN the timing of a recent launch, a chronograph of extremely simple construction was used. The accuracy with which it recorded the speed of the ship is an excellent illustration of how a correctly designed apparatus may be made to serve a purpose, even though it lack expensive finish.

Formerly, launches at this yard have been timed in the usual manner, by painting a series of marks on the ship's side, and timing these with a stop-watch. Two observers stand at a sight, which is in line with the stern of the ship. One holds a stop-watch, on the crystal of which is pasted

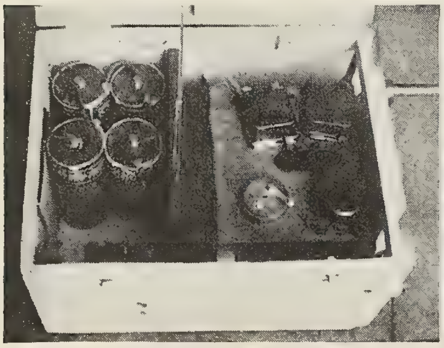

Fig. 1

Fig. 2

a narrow ring of paper, and the other observes the transit of the marks on the ship past the sight. The watch is started when the ship starts, and as each mark passes the sight, the observer taps the shoulder of the man with the watch, and the latter marks on the ring of paper the position of the watch-hand. As a check, a second pair of observers takes a duplicate record.

Errors to Which Stop-Watch Method Is Subject

This method is subject to the following personal errors, which, with the exception of the third, may be in either direction:

1. The error in estimating the instant of transit of the mark.
2. The error between the estimated instant of transit and the signal to the man with the watch.

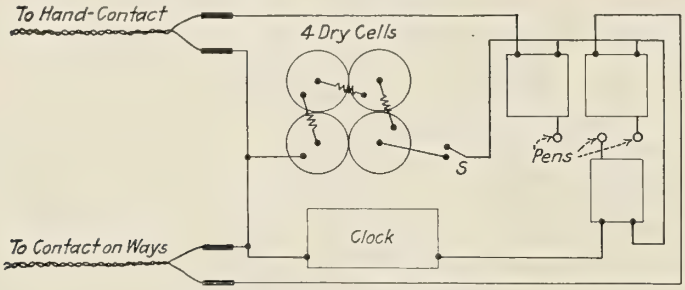

Fig. 3.—Wiring Diagram

3. The lag between the signal and the marking of the watch.
4. The error between the mark and the actual position of the watch-hand.

The start of the ship, in particular, is sure to be recorded too late and, in general, it cannot be said with certainty that the time recorded is within a half-second in either direction of the correct time.

During the first few moments of the launch, where the acceleration curve is most useful in determining the coefficient of friction, unmixed with water-resistance, the above method is especially unsatisfactory, because points cannot be obtained as close together as would be desirable for this rapidly changing portion of the distance-curve, and because the observers, not having gotten into the swing of their work, are especially inaccurate at the start.

Description of the Chronograph

These considerations led to the design of the chronograph shown in Fig. 1. It consists essentially of three pens, beneath which is drawn a strip of paper. The pens are held by ordinary electric bells, from which the gongs and their supporting arms have been removed. The balls on the hammers are replaced by clips to hold the pens. The vibrators are short-circuited with drops of solder.

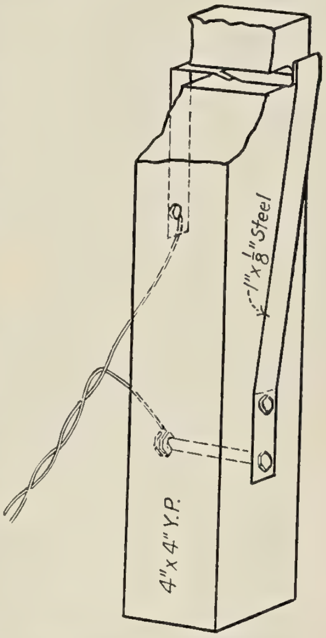

Fig. 4.—The Contactor

The middle pen is operated by the escapement of an alarm-clock, which closes a circuit, and so makes a jog in the line every half-second. One of the other pens is operated by a contactor on the ground-ways, which is closed momentarily as each of a series of stops on the sliding-ways reaches it. The third pen is operated by a contact-maker closed by hand at the sights before mentioned, as the marks on the ship's side pass the station. Thus two independent records are obtained. A wiring diagram is shown in Fig 3.

The clock which operates the middle pen is shown in Fig. 2. The works of an ordinary alarm-clock are mounted on a board, which also carries a copper shelf, to which is soldered a cup made from a revolver-shell. This cup holds a drop of mercury, and a small wire soldered to the escapement lever dips into the mercury at every stroke, thus closing a circuit. One wire is led to the shelf, the other to the frame of the clock. The clock is so made that the mercury contact occurs every half-second. Of course any clock may be used, after timing the beat.

The paper ribbon—an ordinary adding-machine ribbon

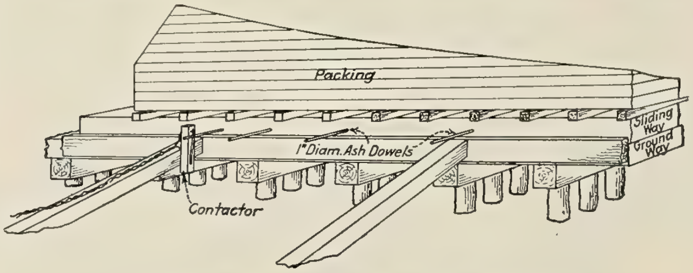

Fig. 5.—Arrangement on the Ways

was used—is wound from one roller beneath the pens onto another roller by a hand crank. The speed of the paper does not need to be exactly constant, for the number of seconds recorded between contacts will be the same, whether the paper is moving rapidly or slowly.

The Contactor

The contactor on the ground-ways is shown in Fig. 4. It consists of a spring of 1-inch by ⅛-inch steel, about 12

inches long, mounted on a piece of 4-inch by 4-inch pine. This is firmly fastened to a ground-way shore, far enough out to clear all obstructions on the sliding-ways, and as far aft as possible. When the spring is pressed home, it makes a rubbing contact with another piece of steel as shown. The

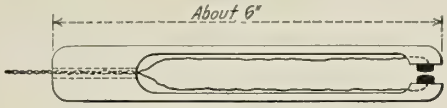

Fig. 6.—The Hand Contact-Maker

contact is made in the middle of the piece of pine, where it is well protected from flying grease from the ways, or from any other interference.

The contactor is closed by 1-inch diameter ash dowels, driven into holes in the sliding-ways, and long enough to provide for the greatest lateral movement that can occur. These dowels come against the contactor, close the spring, and then break off. The first one is placed just ahead of the contactor, so as to close it the instant that the ship starts. These dowels can be placed much closer together than can the marks on the ship's side, as the chronograph will record them as fast as they come. In this instance they were spaced so as to give contacts at roughly constant intervals of one second. The arrangement on the ways is shown in Fig. 5. The contact-maker used by the observer at the sights is shown in Fig. 6.

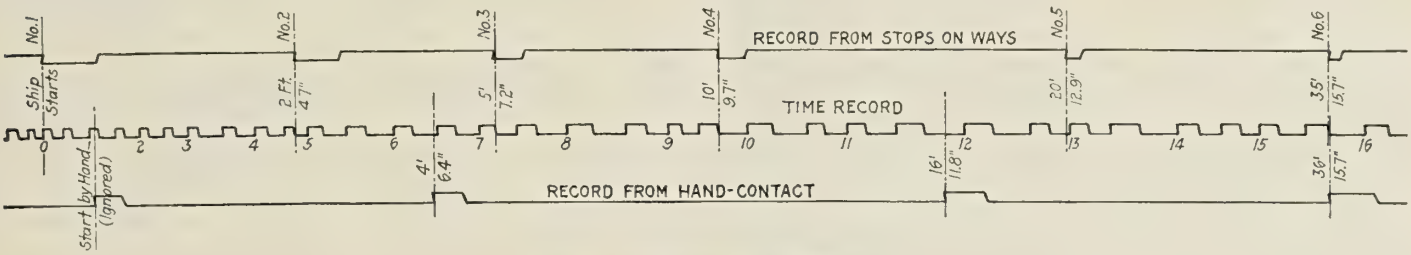

Fig. 7.—Section of the Ribbon

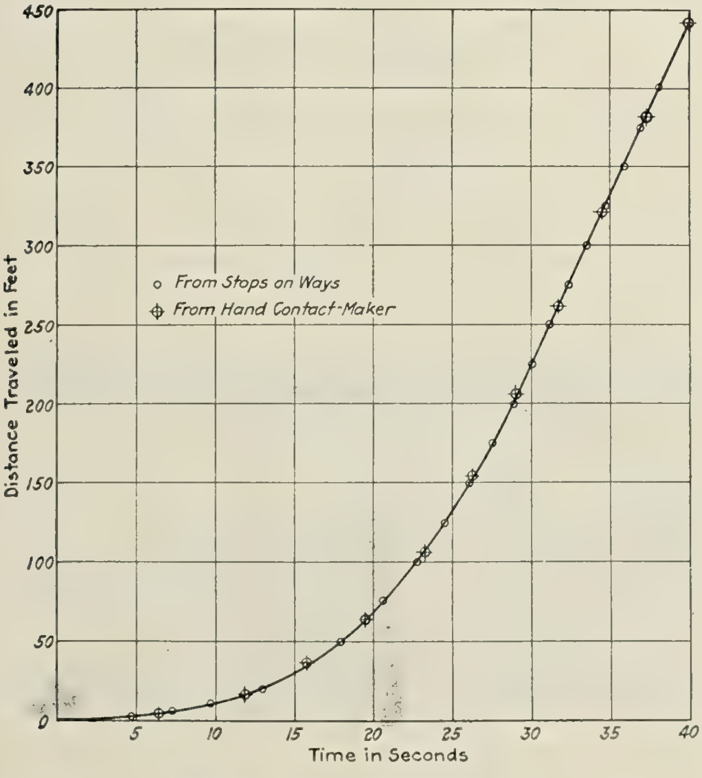

Fig. 8.—Time-Distance Curve

RECORD OBTAINED FROM THE APPARATUS

The ribbon obtained from the launching is shown in Fig. 7. The middle line is the time record, the upper line is the record of the automatic contact on the ground-ways, and the lower line is the record from the contact-maker operated by the observer. The time-distance curves from these data are plotted in Fig. 8. It is impossible to draw two separate curves. The points come much closer to a curve than any stop-watch record that has come to the writer's attention. In fact, it is difficult to put a satisfactory curve through the usual stop-watch data, and the resulting coefficient of friction does not deserve the confidence that can be given the coefficient derived from the curves shown here.

SUMMARY OF ADVANTAGES

To summarize the advantages found in using the chronograph as compared with the stop-watch method:

The work is done by two men instead of four.

The chronograph costs no more than one of the two watches.

Points on the curve can be obtained much closer together than can be marked on a watch.

Each of the records obtained is far more accurate than the stop-watch records—the automatic record being accurate probably to one-tenth of a second, and the hand-recorded time being accurate to about one-fifth of a second.

Unusual Opportunity for Young Men to Secure a Technical Education

ALTHOUGH at the present time the outlook for shipbuilding in this country is not very roseate, it will not long continue to be depressed and there will be ample opportunities for young men to find employment in naval architecture and shipbuilding. At the Webb Institute of Naval Architecture at Sedgwick avenue and 188th street, New York City, founded by the generosity of America's greatest shipbuilder, Mr. William H. Webb, and constituting the only educational institution in this country devoted solely to naval architecture and marine engineering, any young American, between the ages of 15 and 21, can secure a thorough education without any cost to himself whatever. This actually includes board and lodging throughout the entire course and represents one of the finest opportunities for ambitious youths that exist anywhere.

The young men must, of course, be of good character, and have a preliminary education equivalent to that given at the recognized high schools. No matter how many vacancies may exist, the standards are never lowered. They are such, however, that any ambitious youth may seek to obtain an appointment, if he is diligent and applies his attention to the necessary studies. Webb graduates are recognized at all the great shipbuilding centers as splendidly prepared, and they usually have no difficulty in obtaining good positions.

Full particulars as to the examinations, which are to be held in September next, will be furnished by the Resident Manager on application to the address above given.

Admiral Taylor, Chief Constructor of the United States Navy, to Resign on July 1

REAR ADMIRAL DAVID W. TAYLOR, chief constructor of the Bureau of Construction and Repair, U. S. Navy, has tendered his resignation to take effect July 1. Captain John D. Beuret has been nominated by President Harding to succeed him as chief constructor with the rank of rear admiral.

Admiral Taylor has been chief of the bureau for more than eight years and both foreign and American naval officers concede him to be one of the most distinguished technical officers that ever graduated from the Naval Academy. The design of modern warships of all navies has been more influenced by his work than by any other single individual.

Rear Admiral David W. Taylor, U. S. N.

As a student, Admiral Taylor held a record that has never been equalled for the general average of standing in all studies both at the Naval Academy and at the Royal College of Naval Constructors where he was sent under an agreement with the British Government to complete his professional studies.

It was largely due to his efforts that the model basin at the Washington navy yard was established. Through the use of this basin it has been possible through tests on hull models to determine accurately in advance of the actual construction of giant warships exactly what horsepower was needed to assure a given speed. It was while Admiral Taylor was at work at this basin that he worked out through a long series of tests with models the data for his books covering the subjects of resistance of ships and screw propulsion and the speed and power of ships which are international standard works today.

The high esteem in which Admiral Taylor is held in England was shown when the *Olympic* collided with the British cruiser *Hawk* in the Mersey river a few years before the war. The British Admiralty and the British Board of Trade were unable to come to a decision as to the responsibility for the collision and the United States Government was requested jointly by the British Admiralty and the White Star Line to send Admiral Taylor to England to give expert testimony. He went over there and explained the mystery by showing how the vast hull of the *Olympic* would set up drawing forces on the small hull of the cruiser when passing slowly by her.

Admiral Taylor has been a prominent member of the Society of Naval Architects and Marine Engineers. During the war he was a member and is still a member of the Advisory Committee on Aeronautics, chairman of the Joint Army and Navy Zeppelin Board and Army and Navy Aircraft Board. Hundreds of millions of dollars of contracts for new naval ships were virtually under his control during the war and it was also his bureau that developed the monster sea planes, including the *N.C.*-4, which successfully crossed the Atlantic ocean.

Thousands of Feet of Plywood Panels to Be Installed on the Leviathan

THE reconditioning of large vessels such as the *Leviathan* is now accomplished more rapidly than heretofore due to the fact that there is little or no delay in joiner work. The joiner work on most of the German liners taken over by this Government was made of plywood panels. Until recently no facilities were available in this country for doing this large panel work but during the war, in Grand Rapids and Ludington, Mich., were established the large plants of the Haskelite Manufacturing Corporation, where eight large hot plate presses were installed for the purpose of making large panels by the hot plate method using blood albumen glue, the glue which during the war ranked highest by Government test of all glues tested.

On the *Leviathan* there will be thousands of feet of large Haskelite panels, many of which will be 7 feet by 11 feet and larger. In the manufacture of panels by the Haskelite or hot plate method each panel is handled separately and given individual attention in its manufacture. In the large presses, shown in Fig. 1, there are three openings. In each opening one panel is placed at a time. The panels are subjected to heat of 212 degrees F. and over and a pressure up to 250 pounds per square inch. The actual making of a panel and the setting of the glue in these presses takes less than four minutes for each pressing on panels that are not in excess of 5 feet by 8 feet. On longer panels they are pressed a section at a time, the operation being continuous as the plies of wood are fed through the openings 5 or 8 feet at a time depending on which way the press is used.

The fact that these panels can be made up so quickly, are lighter in weight, more economical in space, more sanitary and more attractive, and can be installed so much more rapidly than tongue and groove bulkheads has made them popular in many of the largest yards on both coasts.

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Development of Shell Plating

Q. (1157).—In the development of shell plate in the mold loft by the triangulation method, the question as to which diagonal is the correct one to use has arisen. The triangulation as we work it is the expansion of the plate edge as picked up from the body plan, and the girth (not the true, but the unexpanded girth) with the diagonal.

A. (1157).—The method illustrated in your sketches is in general accord with the principles of the so-called simplified triangulation method. The use of this method should be confined to plates which have very little shape because of the correction for the girths along frames which must be

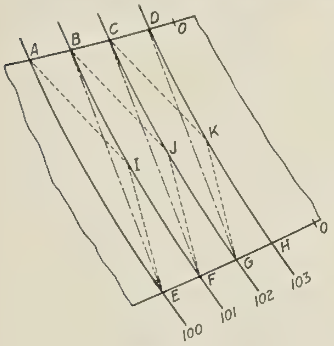

FIG. 1

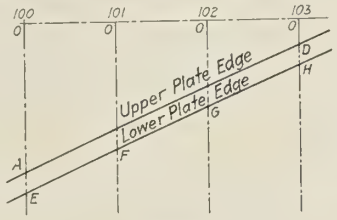

FIG. 2

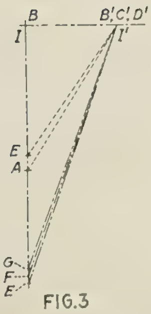

FIG. 3

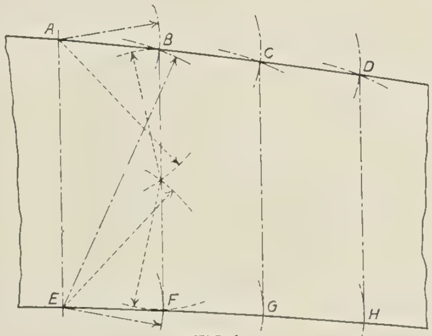

FIG. 4

introduced in connection with this method for plates having much bend and to which you refer as your last step.

You do not specify which diagonals you have in mind in your question. Instead of those shown, EB, FC, etc., it would, of course, give equally satisfactory results if we used AF, BG, etc.

The standard method of triangulation which is very accurate, even for plates having a fair amount of curvature, differs from that shown in its use of two rather than one diagonal. This method is shown, in so far as it differs from the simplified method, by dotted lines in the figures. In principle the two methods are the same but the use of the two diagonals EI and AI, instead of EB, eliminates the necessity of correcting for the girths along the frames. A development of this method is used for plates of pronounced curvature such as bilge plates.

Problem of the Hull and Its Screw Propeller

Q. (1160).—Referring to the April, 1921, number and Admiral Dyson's article, "Problem of the Hull and its Screw Propeller," on page 320 a formula is given for "the mean tip clearance." As I understand the article, this formula is for wing screws. What will be the formula for "tip clearance" for propellers of single screw ships?

On page 319, how is the "K" coefficient to be determined for a ship of Type 1; also for single screw type 3, twin screw type 2, and single screw vessels, type 2, twin screw type 3, if in each case the slip K. B. C. is .7 and the mean T. C. 2.5? I fail to understand how the result is to be read on the curve after the point is spotted for mean T. C., and slip K. B. C.

A. (1160).—The formula to which you refer is to be used only for Type 1 vessels having wing propellers. No formulas are to be used for other types of vessels or other arrangements of propellers.

In designing Type 2 single screw vessels and Type 3 deep draft twin screw vessels take their K value from Curve C_3-C_2, while Types 1 and 3 single screw, Type 2 twin screw and Type 3 twin screw shallow draft vessels take their value of K from Curve C_1-C_2.

For a Type 1 vessel having wing screws, plot your slip K. B. C.=.7 and Mean T. C.=2.5 on the chart referred to and it will be seen to fall between the "Curves of K" marked 1.2 and 1.175. The interpolated value would be approximately 1.18.

For all other types of vessel and number of screws the slip K. B. C. only is to be considered in design with the following results: K for single screw Type 3=1.35. K for twin screw Type 2=1.35. K for single screw vessels Type 2=1.093. K for twin screw Type 3, shallow draft=1.35. K for twin screw Type 3, deep draft=1.093.

Oil Heating Coils in Boiler Furnace

Q. (1161).—Why would not a coil of pipe within the furnace adjustable as to location to secure the proper temperature be better than steam heaters for an oil burning installation, and what would be its advantage or disadvantages?

A. (1161).—The placing of fuel oil heating coils in a boiler furnace has but few advantages and many serious disadvantages. Such an installation would be impossible to control as to temperature no matter where placed, as the intensity of the heat in the furnace will vary as the number of burners operating is increased or decreased. In case the heat became too intense or should there be for any reason a stoppage in flow of fuel, the oil would carbonize in the coils, making it impossible to start up again until the coils had been taken out and cleaned.

The coils would be out of reach of inspection and repair, both of which would have to be frequently made due to burning of the coils. The heater could not be by-passed because, should the oil be left in, it would carbonize, as stated above; and if drained off the coils would burn through. In case of burning out while operating, a stream of oil would be thrown into the furnace; which would probably cause the boiler to pant badly with perhaps serious results.

About the only points in favor of such a system would be the saving of space in the boiler room or in case there should be no available steam.

LETTERS TO THE EDITOR

Marine Boilers

In the April, 1922, issue is an interesting letter by Mr. F. W. Dean, of Boston, Mass., relative to marine boilers which does not accurately cover this subject.

Generally speaking, all reliable published tests to date show that the watertube boiler is more efficient than the fire tube type whether of Scotch marine design or externally fired as used in shore plants. This fundamental fact is further proved by the trend of modern development both ashore or afloat as is clearly shown by the increasing numbers of watertube boilers being purchased and installed as compared with the decreasing number of fire tube boilers being used. This, in the final analysis, is the best evidence of the superiority of the watertube boiler.

Referring specifically to the bent tube type boilers in the

Berengaria, Leviathan, Great Northern, Northern Pacific and some of the "State" ships of the Shipping Board, the four ships mentioned have large tubes; namely, 2-inch, which if properly handled and fed with pure feed water are satisfactory for merchant marine service. The "State" ships built by the Bethlehem Shipbuilding Corporation at Sparrows Point, Md., have small bent tube type Yarrow boilers; namely, 1-inch and 1¼-inch. These tubes, while satisfactory in the Navy, have not proven satisfactory in the merchant marine as it is impossible to clean them internally with any present day known methods. The boilers of the *Great Northern* and *Northern Pacific* are a modified two-drum type designed by Mr. John Mitten, chief engineer, Wm. Cramp and Sons Ship and Engine Building Company, and installed by the Babcock & Wilcox Company.

The Emergency Fleet Corporation has tested out both Scotch and watertube boilers. A comparison of the two sets of tests does not show any superiority in efficiency for the Scotch boiler. In the case of the Scotch boiler tested by them it was fitted with a Foster waste heat superheater and a Howden type forced draft air heater. Adding the heat absorbed by these two auxiliary devices the efficiency of the Scotch boiler is as shown in the accompanying table of tests. So far as I know, these are the only reliable tests made of a Scotch marine boiler.

Any boiler steaming test that will not bear the careful analysis of a heat balance can hardly be considered reliable. It will be noted from the heat balance of the tests quoted that with the highest efficiency shown, namely, 84.3 percent, there was an unaccounted loss of less than 2 percent. In other words it is possible with an exceptionally careful testing crew, having all the known scientific apparatus available, to obtain approximately 86 percent efficiency from a Scotch boiler, a waste heat type superheater and an air heater. Some of the British tests shown in the table attached to Mr. Dean's paper have the impossible efficiency of 89.5 percent and therefore can hardly be considered reliable.

There are no known similar tests of a watertube boiler fitted with the waste heat absorbing devices which were used to increase the efficiency of this Scotch boiler. There are, however, reliable tests published of watertube boilers having efficiencies of over 84 percent without the aid of these auxiliary heat absorbing devices which are required by the Scotch boiler to equal the performance of the watertube boiler.

In the past, at relatively low pressures, there was unquestionably a field for the Scotch boiler. In the future, with the demand for increased economy, there will be little if any field for the Scotch boiler, particularly as increased economy necessarily means higher steam pressures.

Jos. J. Nelis, Secretary,
New York. Foster Marine Boiler Corporation.

Information Wanted

Joseph Wolff, chief engineer of the new White Star liner *Majestic,* has an important personal quest to take up in seeking a younger brother who dropped out of sight at Oakland, California, two years ago and has not been heard from since by his family, who live in England.

The man sought is Fred Wolfe—the brothers spell their surnames differently—aged 37. During the war he was employed as an engineer on the Red Star Line steamship *Lapland,* plying between New York and Antwerp. He left that occupation to engage in war work, which took him to Oakland, where he was employed as a machinist in a shipyard. His last address known to his brother was 426 26th street, Oakland.

Wolfe last communicated with his family in March, 1920, when he appeared to be in good health and spirits. He was always a dutiful father—he was a widower with two children—and had always communicated regularly with his people. When his letters ceased, his brother became anxious and wrote to Oakland, but without learning the circumstances connected with his brother's leaving there.

Chief Engineer Wolff is prepared to seek information of his brother through every possible source. Telegraphic information may be sent him care of *S. S. Majestic,* White Star Line, Pier 59 North River, New York.

NEW BOOKS

The Engineering Index, 1921. Size, 6½ by 9¼ inches. Pages, 584. New York, 1922: The American Society of Mechanical Engineers.

The current issue of The Engineering Index contains over 14,000 items referring to articles in some 600 engineering and allied technical publications published in 1921. In selecting these items the engineering staff of the American Society of Mechanical Engineers has reviewed the 1,200-odd periodicals, reports and other publications regularly received during the year by the Engineering Societies Library, New York, and which, it is believed, comprise the most complete collection of scientific and engineering publications in the world. The Index, therefore, gives to the engineer or scientist a key to the wealth of technical information published during the year. Each item contains the exact title of the article indexed; the author's name, if given; the name of the periodical in which the article appeared; the volume, number and date of publication; the page numbers and number of figures in the article; and a brief note concisely summarizing the contents of the article. The items are arranged alphabetically under main and sub-headings and carefully cross-indexed for reference purposes.

Waste in Industry. By the Committee of Elimination of Waste in Industry of the Federated American Engineering Societies. Size, 5¾ by 9 inches. Pages, 409. Illustrated by numerous charts and diagrams. Washington, D. C., 1921; Federated American Engineering Societies. New York, 1921: McGraw-Hill Book Company, Inc.

Representing the result of five months of intensive study, carefully planned and rapidly executed by no less than eighty of the foremost engineers of the country and their associates, this report, which embodies the first work undertaken by the Federated American Engineering Societies in rendering public service, reveals facts of incalculable value which may serve as a foundation for an advance in American industry. The report is divided into three parts: (1) giving a summary of detailed reports covering sources and causes of waste and recommendations for elimination of waste, (2) details of the engineers' field reports covering six major industries, of varied character and enormous annual output, and (3) general reports on specific industrial conditions such as unemployment, strikes and lockouts, accidents, health, etc. This report is the first instance of a collective or group endorsement of a general analysis of the sources and causes of waste and recommendations for its elimination. Its benefits will undoubtedly be far reaching as it points the way for locating and eliminating waste in other industries.

The thirtieth annual edition (1922) of Hendrick's Commercial Register, published by S. E. Hendricks Company, Inc., 70 Fifth Avenue, New York, contains 2,300 pages and comprises a thoroughly indexed and carefully classified register of producers, manufacturers, dealers and consumers connected with the electrical, engineering, hardware, iron, mechanical, mill, mining, quarrying, chemical, railroad, steel, architectural, contracting and kindred industries. The products are listed from the raw material to the finished article with the concerns handling them from the producer to the consumer.

Sternwheel Towboat for Mississippi River Service

(*Continued from page* 371)

capacities ranging from 5,000 to 9,000 barrels, a maximum distance of 150 miles. The oil will be discharged by means of pumping equipment located on the barges. Steam will be furnished from the boilers on the towboat at places where it cannot be obtained from shore. To provide for this, four 1½-inch steam connections have been provided on each side of the boat, two at the forward end of the main deck house and two at the after end of the boilers. When engaged in pumping it is proposed to operate a single battery of boilers.

The cabin, hurricane deck and pilot house are of wooden construction. Panels of 5/16-inch material attached to a light framework are used for the siding and partitions of the cabin to obtain a construction of light weight. A skylight the full length of the cabin provides for the proper ventilation of the quarters.

The hull and machinery plans for this boat were required to meet the approval of the American Bureau of Shipping for river service.

The Economic Efficiency of Merchant Ships

(*Continued from page* 390)

$$(f' C' - x T - q' F)]$$

where

$$F = k\, l\, \triangle^{2/3} V^2 L = \text{total fuel}$$

and the condition that E is a maximum is $\frac{\partial E}{\partial V} = 0$.

$$\therefore [(n_L V + L)(f' C' - x T - 3 q' F) - n_L V (f' C' - x T - q' F)] = 0$$

$$\therefore f' C' L - x T L - 3 q' F L - 2 q' F n_L V = 0$$

Whence

$$\frac{q' F V}{L}\left(\frac{3 L}{V} + 2 n_L\right) = f' C' - x T$$

And substituting

$$F = k\, l\, \triangle^{2/3} V^2 L$$

$$q' k\, l\, \triangle^{2/3} V^3 \left(\frac{3 L}{V} + 2 n_L\right) = f' C' - x T$$

the value of V which satisfies this equation will thus be the best speed V_B.

4. Condition for constant "best" speed when f and q vary

$$\frac{\partial V_B}{\partial f}\,\delta f' + \frac{\partial V_B}{\partial q}\,\delta q = 0$$

where

$$\frac{\partial V_B}{\partial f'} = \frac{1}{q'}\,\frac{C' q + r x T}{(q' k\, l\, \triangle^{2/3})(L + n_L V_B)\, 6 V_B}$$

$$\frac{\partial V_B}{\partial q} = -\frac{1}{q'}\,\frac{f' C' - x T}{(q' k\, l\, \triangle^{2/3})(L + n_L V_B)\, 6 V_B}$$

and substituting

$$\frac{\delta f'}{\delta q} = \frac{f' C' - x T}{q C' + r x T}$$

The equation is linear, and the effect of tonnage is to reduce the slope of the curve somewhat.

PERSONALS

A. R. Hunt, general manager of the Seattle plant of the Todd Shipyards Corporation, has been made vice-president.

J. E. Murphy, former traffic manager of the Emergency Fleet Corporation, has been appointed head of the division of passengers and mails of the Shipping Board.

Harry W. Kent, hitherto vice-president of the Todd Dry Docks Company of Seattle, has been made president of both the Seattle and Tacoma plants, succeeding C. W. Wiley.

William M. Truss, formerly with the Bethlehem Shipbuilding Coorporation, has been appointed marine sales manager of the Pusey and Jones Company, Wilmington, Del.

Alfred Buchi, chief engineer of Sulzer Bros., the Swiss manufacturers of the Busch-Sulzer Diesel engine, is at present in New York and will visit several other cities in the United States to study our methods of Diesel engine construction before returning to Switzerland.

Joseph T. Sheedy, European manager for the Emergency Fleet Corporation at London, has been made acting director of physical operations, with headquarters at Washington, D. C.

J. E. Andrews, who has been assistant to W. B. Keene, traffic manager of the Shipping Board, has been appointed head of the European division at Washington, succeeding F. G. Frieser.

David V. Stratton, well known in shipping circles and formerly holding an important position with the United States Shipping Board, has succeeded Lloyd Adam Noble with the Morse company.

Roy Parris has been appointed resident inspector on the 285-foot car ferry now building for the Missouri and Illinois Railroad at the plant of the Charles Ward Engineering Company, Charleston, W. Va.

Huntington T. Morse, former assistant to Joseph T. Sheedy, European manager of the Emergency Fleet Corporation, will succeed Mr. Sheedy in this capacity, still retaining the main office in London.

Harry Brown has tendered his resignation as a director and as technical manager of the Bethlehem Shipbuilding Corporation, Ltd., effective June 1. On this date Mr. Brown leaves for an extended vacation.

Lloyd Adam Noble, formerly manager of the New York office of Morse Dry Dock and Repair Company, has resigned his position and is now connected with the firm of W. and A. Fletcher Company, Hoboken, N. J.

C. W. Wiley, former president of the Todd Shipyards Corporation plants at Seattle and Tacoma, Wash., has been made chairman of the Board of Directors and personal representative of William H. Todd on the Pacific coast.

Allen Prangnell, who has been in the chartering department of S. O. Stray and Company of New York, will succeed W. L. Bull as head of the Mediterranean division of the United States Shipping Board at Washington.

V. J. Freeze, manager of the traffic department of the United States Shipping Board at Baltimore, will succeed Allan McLane, Jr., as head of the Far East and long voyage trade division of the traffic department at Washington.

W. L. Bull, in charge of the Mediterranean division of the Shipping Board at Washington, D. C., will be transferred to New York to succeed George H. Wells, who recently resigned as head of the European section of the New York office.

F. G. Frieser, in charge of the European division of the Washington offices of the Emergency Fleet Corporation, has been appointed special assistant to W. B. Keene, traffic manager and will have under his supervision homeward rates and traffic.

Louis F. Klein of New York has been appointed manager of the inland offices division of the Emergency Fleet Corporation traffic department. Mr. Klein has for many years been connected with railroad traffic work and has in addition made a thorough study of steamship operation.

Allan McLane, Jr., who has been head of the Far East and long voyage trade division of the traffic department of the United States Shipping Board Emergency Fleet Corporation in Washington, will shortly leave for England, where he will be connected with Runciman, Ltd., London, agents for the United States Lines.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

More Than Sixty-Two Vessels Are in Course of Development as Part of New Construction Program for 1922

Shipbuilding Outlook for This Year Gives Renewed Cause for Optimism—Inquiries Becoming More Numerous and New Contracts Being Signed

THE construction of over sixty-two vessels as a part of 1922's shipbuilding program, which has been forecasted frequently by MARINE ENGINEERING AND SHIPPING AGE, seems nearer at present than at any time so far during the year. While there are a few ships already contracted for and under construction at the present time there is a steadily increasing number being brought out as "in contemplation" and while it is possible that all of the new ships under consideration will not reach the actual construction stage, there is every reason to believe the majority of the vessels now being planned tentatively will sooner or later be built. As concrete evidence that American shipbuilding is recovering rapidly from the recent depression, a total of sixty-two vessels are listed below of which seven have been definitely contracted for or are already under construction.

The Department of Plant and Structures of the City of New York has awarded a contract for the construction of three turbo-electric ferries to the Staten Island Shipbuilding Company to be built at a total cost of $1,589,900. The same department is working on plans and specifications for seven Diesel electric ferries for the East River routes.

The signing of contracts for seventeen electric drive freighters, designed by Theodore D. Wells, naval architect of New York, for ocean and river service for the Central Steamship and Commerce Corporation and also for five Diesel electric cargo boats of special design by R. R. Livingston, naval architect of New York, for the Canal and River Transportation Company, is considered more imminent now than at any time since the work was proposed.

Taken in conjunction with the proposed construction of 10 ships for the New England Oil Refining Company; six for the North Atlantic and Western Steamship Company (Nawsco Line), which is said to be considering motorships; two steamers for the Eastern Steamship Company, plans and specifications for which are now nearing completion; two for the Old Dominion Steamship Company; two for the Red "D" Line; two for the Cleveland and Buffalo Transportation Company; one for the Catskill Evening Line; one for the Savannah Line; two recently contracted for with the Federal Shipbuilding Company by the Merchants' and Miners' Transportation Company; two being built by the Pusey & Jones yard for the Seaboard-Bay Line, the shipbuilding and equipment prospects appear in a brighter light than has been evident in many months.

Contract Is Placed for New 600-Foot Great Lakes Steamship

THE American Shipbuilding Company, of Cleveland, Ohio, has been awarded a contract by the Franklin Steamship Company of Cleveland for the construction of a new steamer at a cost said to be close to $800,000.

The new steamer will be 600 feet in length, 64 feet beam by 33 feet deep and will be equipped with three Scotch boilers, 14 feet diameter by 11 feet long and a triple expansion engine with cylinders 25½ by 41 by 67 with 42 inch stroke. The vessel is for use on the Great Lakes.

New Ferryboat to Be Built by Staten Island Yard

The Staten Island Shipbuilding Company of Staten Island, New York, has been awarded a contract for the construction of a ferryboat for the Erie Railroad.

It is understood that the new vessel will be a duplicate of the ferryboat *Jamestown*, operated by the same company, which is 206 feet long, 44 feet beam, driven by a two-cylinder compound engine, 18 by 38 by 28, developing 1,200 indicated horsepower, steam being supplied by two single-ended Scotch boilers having a working pressure of 150 pounds of steam. The *Jamestown* was built by the same shipyard in 1907.

Two Steel Quarter Boat Hulls to Be Built for Nashville

Sealed proposals will be received by U. S. Engineer Office, Nashville, Tenn., until 11 A. M., June 26, 1922, for constructing two steel quarter boat hulls. Further information on application.

Specifications For Converting Four Steel Ships Expected Soon

Admiral Line Vessels to Be Made Into Motorships, Costing Over Quarter Million

PROSPECTS for the issuance of specifications for the conversion of the steel auxiliaries *Dawnlite, Daylite, Starlite* and *Moonlite* into motorships, which it is understood will involve the expenditure of a total of close to $300,000 or over, for the Admiral Line, have improved materially, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE.

The boats are of about 3,000 deadweight tons each and while definite plans have not yet been made it is understood that three of the barges may be equipped with Diesel engines and electric auxiliaries and one equipped with Diesel engines and steam auxiliaries. It is also reported that the auxiliaries are to be taken from certain wooden ships acquired by the Admiral Line on the Pacific Coast.

Indications are that the Admiral Line will request bids for the conversion work from shipyards on both the Atlantic and Pacific coasts.

Bids May Be Asked in Near Future for Fleet of New Special Type Tankers Costing Millions

Foreign as Well as American Shipyards Will Submit Figures on Vessels Proposed by New England Oil Refining Company for South American Service

BIDS are expected to be asked in the near future for the construction of a number of self-propelled oil carriers possibly from 10 to 15 for the New England Oil Refining Company of 25 Broadway, New York City, which is understood to be contemplating the construction of such boats for service on Maracaibo Lake, South America. If such a program is carried out, from three to six million dollars may be expended in the construction of a special type steel ship. It is also understood that the company will obtain bids from foreign shipbuilders as well as from yards in America.

Details concerning the preparation of final plans and specifications were not available at present, although it is considered likely that the ships will be close to 300 feet in length with the strong possibility that the propelling machinery would consist of triple expansion steam engines with steam supplied by two Scotch boilers. In order to meet requirements, the vessels will probably have a draft of 10 or 11 feet in order to make the passage to and from Maracaibo Lake.

Plans Being Pushed for Seven Diesel-Electric Ferries to Be Built For East River Service, New York

Final Specifications Will Provide for Steel Boat 175 Feet Long, Driven by Two 400-Horsepower Diesel Engines—Hope to Ask for Bids Before Summer

PLANS and specifications for the construction of a total of seven Diesel electric ferryboats by the Department of Plant and Structures of the City of New York, for service in the East River, are well under way, according to an announcement by Commissioner Grover A. Whalen. The bids for these vessels will probably be received within a few weeks and it is estimated that the boats will cost a total of approximately $1,540,000.

With regard to the construction and equipment of these ferries, Commissioner Whalen said:

"We have designed a boat 175 feet long over all with a breadth of 64 feet, having ascertained by actual experience that this is the best size for handling in congested waters of the East River with its peculiar currents and eddies.

Construction

"We propose to build the boats of steel, with five watertight compartments in the hull, with three vehicle gangways and cabins for passengers on the overhang on each side. By abandoning the old steam engine type and using screw propellers instead of side wheels we can have the room for the third runway.

Propulsion

"We are considering installing in each boat two 400-horsepower engines of the Diesel type. Specifications are being prepared that permit of the widest possible competition, under which engines of the solid fuel injection type or of the high pressure air atomized type may be used.

"There are several makes of engines of each of these types that have demonstrated their dependability, such as Ingersoll-Rand, Worthington and De LaVergne of the former type, and the Werkspoor, Winton, New London, McIntosh & Seymour and Busch-Sulzer of the latter type.

"A generator will be direct connected to each engine producing the electric current to propel the boat at a speed of 12 miles an hour and to operate the auxiliary machinery.

Control.

"It is designed to install three master controllers, one in each pilot house and one in the engine room, so that the pilot can control the starting, stopping and reversing and regulate the speed, or the control can be taken over by the engineer and operated in response to usual ship telegraph and bell signals.

"It is planned to provide service gravity tanks to feed the fuel oil to the engines and storage tanks that will carry ten days' supply. The same fuel will be used for the small steam boiler that will provide heat in winter.

"The preliminary studies have been under way for six months and we are now at work on the actual plans and specifications, hoping to advertise contracts for seven ferryboats of this type before summer."

Fireboat Planned For New Orleans, La., Is To Be Oil Burner

Will Be Driven by Reciprocating Engines and Is to Have Complete Fire Fighting Equipment—Bids June 29

THE Board of Commissioners of the Port of New Orleans are advertising for bids on the construction and delivery of a steel screw fireboat 138 feet 6 inches long, 29 feet beam and 15 feet (inches deep. She will be fitted with compound engines 20½ inches and 46 inch diameters of cylinders and 28-inch stroke.

There will be four turbine driven fire pumps, of a combined capacity of 10,000 gallons per minute at a pressure of 200 pounds per square inch at the pumps. Four 6-inch monitor nozzles will be installed, one on a high tower aft of the main engine hatch, two on platforms amidships, and one on the pilot house. Sixteen hose connections will be provided on the turrets under the midship monitors, and swivel nozzles are fitted on the main rail at intervals. Three steel hose reels on deck will carry about 2,500 feet of hose. There is to be a complete outfit of all modern appliances for fire fighting.

There will be two watertube boilers for 225 pounds working pressure, fitted to burn fuel oil. All auxiliaries are independent. The vessel will be built for classification, but far in excess of all rules. When in action, she will deliver over fifty tons of water per minute. She was designed by and will be built under the supervision of Cornell and Matthews, naval architects and engineers, Philadelphia. Bids will be opened in New Orleans, June 29, 1922, and it is believed the vessel will cost close to $250,000.

Robins Yard of Todd Corporation Low Bidder for Huron Reconditioning

The Robins Dry Dock & Repair Company of the Todd Shipyards Corporation, with a price of $179,000, submitted the lowest tender for reconditioning the steamship *Huron* at the opening of bids by the Shipping Board at 45 Broadway, New York City, on May 12. The prices submitted were as follows:

Robins Dry Dock & Repair Co....	$179,000
Bethlehem Shipbuilding Corp.	183,162
Morse Dry Dock & Repair Co.....	190,900
Sun Shipbuilding Co.	258,578

Fuel Oil Burning Equipment for Army Dredge

Fuel oil burning equipment has been ordered for installation on a United States Army dredge located at Porto Rico. The equipment selected is the Bethlehem (Dahl) mechanical system built by the Bethlehem Shipbuilding Corporation, Ltd., and the installation is being made at Porto Rico. The order was placed through the office of the Second District, United States Army Engineers, New York.

Buxton Line Will Replace Vessels Lost In Fire and Crash

THE Buxton Steamship Company of Norfolk, Va., on April 13, lost in a fire at Berkly the 115-foot oil burning ocean tug *Buxton*, the 216-foot side wheel excursion passenger steamer *Rosedale*, the 135-foot freight steamer *Martha Stevens* and the 71-foot auxiliary twin-screw passenger boat *Watch Hill*.

On April 21 their 176-foot oil burning freight steamer *Brewster* was rammed and sunk by the New York-Richmond Line steamer *Lake Stirling* while en route from Richmond to Norfolk with cargo. Chief Engineer, C. W. Hussey was lost with the *Brewster*. This steamer had recently been overhauled, having new boilers and other new equipment installed.

Disregarding all of these losses, the Buxton Line is reported to be going right ahead, having faith in the future of Norfolk as a port city. It is stated that the company intends to replace all of these ships at some future date but is in the market for a ship to replace the *Brewster* at once, as this boat is needed on the Norfolk-Richmond run.

Standard Oil May Convert Steam Tankers to Motorships

According to latest reports, the Standard Oil Company of New Jersey is planning the conversion of several of its tankers from steamships into motorships. It is understood that propulsion equipment developing close to 3,000 horsepower, driving twin screws, may be installed in each ship converted. Further details as to the number of ships which may be involved, or the amount of money which may be expended, were not available at this time.

Newport News Yard Gets Tanker Libby Repairs

The contract for repairs to the Standard Oil tanker *W. H. Libby*, consisting chiefly of bottom damage effecting 35 plates, has been awarded to the Newport News Shipbuilding and Dry Dock Company. The bids submitted for the work were as follows:

Newport News Shipbuilding & Dry Dock Co.	$34,615
Robins Dry Dock & Repair Co......	37,700
Staten Island Shipbuilding Co.......	38,445
Morse Dry Dock and Repair Co....	43,882

Third Annual Dinner of the Marine Committee of the American Institute of Electrical Engineers at the Hotel Astor, New York, on April 28

Marine Committee of American Institute of Electrical Engineers Holds Third Annual Dinner

Set of Standardization Rules Prepared on Good Engineering Practice Covering Fire Protection and Marine Construction Requirements

THE third annual dinner of the Marine Committee of the American Institute of Electrical Engineers was held at the Hotel Astor on April 28, 1922. This committee was originally appointed by the American Institute of Electrical Engineers in 1913 because of the differences existing between the requirements of various classification societies and insurance companies in regard to electrical installations on shipboard and the lack of any accepted standard engineering practice for marine installations.

Besides arranging for papers to be read at the meetings of the Institute to increase the interest of electrical engineers in marine problems, the committee took up the preparation of standardized rules which would represent good engineering practice and which might be accepted by the classification societies. As a result, a set of rules was prepared covering two important divisions, namely: fire protection requirements and marine construction requirements. These rules were adopted by the committee of the American Bureau of Shipping and were published as Section 37 of the Rules for Building and Classing Vessels issued by that Bureau.

As the first edition of the rules did not cover the entire field of the use of electricity on shipboard, the Marine Committee was continued and a more nearly complete set of marine rules has now been issued which in the arrangement and scope conform to a similar set of regulations issued by the Institution of Electrical Engineers in England. The committee is now undertaking a work of far-reaching importance with a view to establishing approved standards in the application of electricity to merchant ships.

The members of the committee are as follows:

Arthur Parker, New York Shipbuilding Corporation, Camden, N. J., chairman; L. C. Brooks, Bethlehem Shipbuilding Corporation, Quincy, Mass., secretary; J. B. Bassett, General Electric Company, New York; R. A. Beekman, General Electric Company, Schenectady, N. Y.; Eskil Berg, General Electric Company, Schenectady, N. Y.; Maxwell W. Day, General Electric Company, Schenectady, N. Y.; David D. Faris, Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.; E. G. Gallagher, Lake Torpedo Boat Company, Bridgeport, Conn.; H. Franklin Harvey, Jr., Newport News Shipbuilding & Dry Dock Company, Newport News, Va.; William Hetherington, Jr., Cutler-Hammer Manufacturing Company, New York; H. L. Hibbard, Cutler-Hammer Manufacturing Company, New York; J. S. Isdale New York Harbor Dry Docks Corporation, New York; William F. James, Westinghouse Electric & Manufacturing Company, Philadelphia, Pa.; Commander C. A. Jones, U. S. N.; Commander C. S. McDowell, U. S. N.; W. F. Meschenmoser, Russell & Stoll Company, New York; T. H. Osborne, Federal Shipbuilding Company, Newark, N. J.; G. A. Pierce, Jr., William Cramp & Sons Ship and Engine Building Company, Philadelphia, Pa.; Commander S. M. Robinson, U. S. N.; H. M. Southgate, Westinghouse Electric & Manufacturing Company, Washington, D. C.; W. E. Thau, Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.; F. P. Townsend, Kindred Appliances Company, Newark, N. J.; A. E. Waller, Ward Leonard Electric Company, Mt. Vernon, N. Y. and F. W. Wood, Charles Cory & Sons, Inc., New York.

Atlantic Coast Shipbuilders' Association Holds Annual Convention

THE annual meeting of the Atlantic Coast Shipbuilders' Association was held in Philadelphia on Monday, May 8, 1922. Representatives of every shipbuilding district in the East attended the meeting and the list of speakers included W. Averill Harriman, chairman of the American Ship and Commerce Corporation; Honorable George Earle Chamberlain, Commissioner of the United States Shipping Board, and Admiral Louis McCoy Nolton, commandant of the Philadelphia Navy Yard, who spoke with considerable significance regarding a permanent future for shipbuilding as a successful American industry.

It was emphatically stated that America's future on the high seas depends for the most part on liner service and attention was called to the fact that this country is at present greatly lacking in vessels of this class and that every effort should be made to obtain ships that can compete successfully with countries that are our chief rivals in foreign trade.

The following officers were re-elected for the ensuing year: President J. L. Ackerson; vice-president, George H. Bates; treasurer, J. Harry Mull; secretary, Clarence Samuel King.

Federal Shipbuilding Company Low Bidder for Poznan Reconditioning

THE Federal Shipbuilding Company was low bidder for reconditioning the steamship *Poznan* of the Luckenbach Line at the opening of tenders at the Luckenbach pier, Brooklyn, on May 20. The prices submitted were as follows:

Federal Shipbuilding Co.	$207,000
Robins Dry Dock & Repair Co.	224,940
Sun Shipbuilding Co.	229,076
Tietjen & Lang	257,620
Bethlehem Shipbuilding Corp.	272,253
New York Harbor Dry Dock Co.	345,000
Newport News Shipbuilding & Dry Dock Co.	373,000
W. & A. Fletcher Co.	383,000

The work covered by the specifications included the reconditioning of the vessel for certificate of local inspectors of the Panama Canal, Suez Canal and the American Bureau of Shipping. The principal work is to open up all the main engines, overhaul them, remove the boilers, replace with new boilers furnished by the owners, recondition the rigging, recondition the fire fighting system, removing the gun foundations, relocating the king posts, installing a gyro-compass, renovating the cargo pipe system on deck, preparing the tanks for fuel oil including new separate tanks, installing the Peabody oil-burning system complete, reconditioning the wooden decks, overhauling all the communicating systems, reconditioning the fire and floor plates and installation of the Rand fuel oil heating system. The ship is to be renamed the *Frederick Luckenbach*.

Thatcher Propeller Company to Expand Plant

The Thatcher Propeller and Foundry Corporation, Albany, N. Y., is offering for public subscription approximately $250,000 of its new issue of 8 percent cumulative preferred stock and common stock. The object of this issue is to raise capital to permit the purchase of additional machinery, electric travelling cranes, a manganese bronze furnace, the latest type of steel furnace and also raw materials.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Fireboat, New Orleans, La.—Board of Commissioners of Port of New Orleans will open bids June 29 for the construction and delivery of steel screw fireboat, 138 feet 6 inches long, 29 feet beam and 15 feet 6 inches deep. To be fitted with compound engines 20½ inches and 46 inch diameter of cylinders and 28-inch stroke.

Steamship to Be Fitted for Refrigeration.—Plans and specifications for conversion of steamship San Lorenzo, of New York and Porto Rico Line, to carry citrus fruits from West Indies, expected to be completed soon. Work will probably cost close to $100,000.

Repair Contract, Staten Island, N. Y.—Staten Island Shipbuilding Company awarded contract for hull work on pilot boat New York, at opening of bids by United New York-Sandy Hook Pilots' Benevolent Association, Whitehall St., New York, on May 11.

Overhauling of Tanker, New York.—New York Harbor Dry Dock Company awarded contract for general overhauling of hull and machinery of tanker H. C. Bedford, of Standard Oil Company of New Jersey, at opening of bids on May 10. Price $8,021.

Miscellaneous Repairs, Chester, Pa.—W. M. Irish, tanker of Atlantic Refining Company, was drydocked for miscellaneous repairs at Sun yards.

Reconditioning of Steamer, Oakland, Cal.—Repairs amounting to $44,900 made to Pacific Mail liner, Wolverine State, by Moore yards, Oakland, Cal., including installation of steerage accommodations for 219 passengers and changing of the engineers' quarters. Vessel will engage in passenger and freight-carrying trade from San Francisco to Manila and Hong-Kong via Honolulu with her sister ship, the Creole State.

Danish Steamer Repaired, Newport News, Va.—All necessary repairs to Danish ship Anna Meersk made by Newport News Shipbuilding and Dry Dock Company.

Repairs to Brazilian Steamship, Newport News, Va.—Large Brazilian steamer Camamu was repaired at Newport News shipyard. Raleigh-Smokeless Fuel Company, agents for vessel.

Steamer Dry Docked, Galveston, Texas.—The Mundelta drydocked at Galveston, Texas, and underwent repairs caused by damages sustained recently at Sabine when rammed by Shipping Board tanker Mevania.

Steamship at Naval Plant, Seattle, Wash.—The Wenatchee, Shipping Board's big transpacific liner, at Bremerton Navy Yard, Seattle, Wash., for drydocking, inspection and overhauling.

Schooner Repairs, Boothbay, Me.—Schooner Margaret Thomas, undergoing extensive repairs at Boothbay Harbor, which will take several weeks to complete.

New Ship Propeller.—The Grace Liner Colusa shifted to San Francisco, Cal., for drydocking and inspection and installed a new propeller.

Steamer Burns, Havana, Ill.—The 2,500-ton Mississippi River steamer Majestic burned at Havana, Ill. Steamer left Peoria for Havana a few days previous to its destruction.

Dredge Dry Docked, Oregon.—Government dredge Colonel P. S. Michie drydocked for repairs to her propeller and upon completion returned to her station at Coos Bay.

Norwegian Steamship Dry Docked, Philadelphia, Pa.—First vessel consigned to B. H. Sobelman & Company for new Baltic service from Philadelphia, Norwegian steamship Rio Grande, drydocked at Cramp's shipyard, Philadelphia, for bottom painting, before going into berth at Pier C, Richmond.

Miscellaneous Repairs, Chester, Pa.—J. C. Donnell, tanker of Atlantic Refining Company, drydocked at Sun Shipyard for miscellaneous repairs.

General Overhauling of Tug.—The boarding tug Governor Pennypacker, used by the health officers at Marcus Hook, was overhauled at Philadelphia.

Eleven Ship Repair Contracts, Hoboken, N. J.—Over eleven repair contracts were awarded to the W. & A. Fletcher Company, Hoboken, New Jersey, during the week ending May 13. Work provided for both hull and engine repairs and reached a total in excess of $42,000.

Tug on Marine Railway, Philadelphia, Pa.—Tug Henry P. Mills, of Delaware River Towing Company, recently went to Marine Railway at Philadelphia Ship Repair Company's yards. Her machinery was disabled.

Dredge Repaired, Portland, Ore.—The Colonel P. S. Michie went to Portland, Ore., for repairs.

Extensive Steamer Repairs, Brooklyn, N. Y.—Contract for reconditioning steamship Princess Matoika awarded Morse Dry Dock & Repair Company, Brooklyn, N. Y.

Specifications for Conversion.—Issuance of specifications for conversion of steel auxiliaries Dawnlite, Daylite, Starlite and Moonlite into motorships, understood to involve a total of close to $300,000 or over, for Admiral Line, expected soon.

Bids for Tankers, N. Y.—Bids are expected to be asked in near future for construction of a number of self-propelled oil carriers, possibly from 10 to 15, for New England Oil Refining Company, of 25 Broadway, New York City, understood to be contemplated for service on Maracaibo Lake, South America. If such a program is carried out, from three to six million dollars may be expended.

Boat Hulls, Nashville, Tenn.—Sealed proposals will be received by U. S. Engineer Office, Nashville, Tenn., until 11 A. M., June 26, 1922, for constructing two steel quarter boat hulls. Further information on application.

Contract for Steamship, Cleveland, O.—American Shipbuilding Company, Cleveland, Ohio, awarded contract by Franklin Steamship Company, Cleveland, for construction of new steamer at cost said to be close to $800,000. New steamer to be 600 feet long, 64 feet beam by 33 feet deep, and equipped with three Scotch boilers, 14 feet diameter by 11 feet long and a triple expansion engine with cylinders 25½ by 41 by 67 with 42 inch stroke. Vessel for use on Great Lakes.

Ship at Southern Yard.—British steamship Balsa went to Southern Shipyard, having been bought and floated by Captain Griffin, of Norfolk, after being stranded.

Ships at Colonna Shipyards, Norfolk, Va.—Ships in Colonna yard recently were: Barkentines State of Bumont, State of New Orleans and Mercerata, for general repairs to hull and auxiliary machinery; United States Shipping Board steamer American Press, for painting, scraping and bottom repairs; Shipping Board steamer Tenafly, for survey and general repairs; steamship Mazama, repairs to machinery; tug Eastern, general repairs; and fishing steamers Rappahanock, Peconie, E. W. Edwards, M. M. Davis, East Hampton, Dolphin, Northumberland, B. H. B. Hubbard, A. Brooke Taylor, G. S. Allen, D. K. Phillips and the Steven W. McKeever, all for seasonal overhauling. Yard repaired a number of car floats for N. Y. P. & N. Railroad.

Tanker for Repairs, Brooklyn, N. Y.—Contract for repairs to Standard Oil tanker H. M. Flagler awarded to Robins Dry Dock & Repair Company of Todd Shipyards Corporation at $12,495.

Contract Awarded, Newport News, Va.—Contract for repairs to Standard Oil tanker W. H. Libby, consisting chiefly of bottom damage effecting 35 plates, awarded to Newport News Shipbuilding and Dry Dock Company at $34,615.

Steamship Overhauled, San Francisco, Cal.—The Valdez, out of commission all winter, shifted to Heffernan Dry Dock, San Francisco, Cal., for overhauling preparatory to being placed in commission.

Low Bidder for Reconditioning, Brooklyn, N. Y.—Robins Dry Dock & Repair Company of Todd Shipyards Corporation, with price of $179,000, submitted lowest tender for reconditioning steamship Huron at opening of bids by Shipping Board at 45 Broadway, New York City.

Construction of Scows, New York.—Plans and specifications issued and bids will be received by Board of Purchase of City of New York in Room 526, Municipal Building, Borough of Manhattan, from 9 to 10:30 A. M., Monday, June 5, for furnishing to Street Cleaning Department twelve side-dumping scows at cost estimated at close to $250,000.

Contract for Three Ferries, Staten Island, N. Y.—Contract for three steel screw electric-driven ferryboats awarded by Commissioner Grover A. Whalen, of the Department of Plant and Structures, New York, to Staten Island Shipbuilding Company at total cost of $1,589,900.

Five Cargo Boats.—A contract for construction of five Diesel electric cargo boats for Canal & River Transportation Company, New York, and which it is understood will involve expenditure of over $500,000, expected to be placed in near future.

Conversion to Motorships.—Standard Oil Company of New Jersey planning conversion of several of its tankers from steamships into motorships. It is understood that propulsion equipment developing close to 3,000 horsepower, driving twin screws, may be installed in each ship converted.

Steamer Refitted, Seattle, Wash.—Steamship Brookdale, after lying idle in Lake Union a year, has been repaired and refitted for cannery trade at Eagle Harbor plant of the Winslow Marine Railway & Ship Repairing Company, Seattle, Washington. She is one of the largest wooden carriers built for the Shipping Board, being 272 feet long, 49 feet beam, and of 4,200 deadweight tons.

Wooden Steamer Repaired, New Orleans, La.—American steamer Nika, one of wooden vessels built at Moss Point, Mississippi, by Hodge Shipbuilding Company, during the war and completed the latter part of 1919, repaired at Henderson Dry Docks. She was recently bought by F. M. Starks of San Francisco, and entered service at Mobile, taking cargo to Pacific Coast.

Repairs to Steamer, Newport News, Va.—British steamer Madras City repaired at Newport News Shipbuilding & Dry Dock Company's yard.

Renewed Activity, Gloucester, Mass.—Cape Ann Anchor Company, of Gloucester, Mass., has started plant on one-third normal capacity basis after idleness of over five months. A. P. Stoddart & Company, engineers and machinists of Gloucester, Mass., report increasing number of inquiries, also larger volume of business. This plant is making hoisting winches and steering gear for small and medium-sized vessels and are equipped to handle fair-sized marine engine and motor work.

Miscellaneous Repairs, Chester, Pa.—Steamship Ontario, of Merchants & Miners' Transportation Company, drydocked at Sun Shipyard for miscellaneous repairs.

Contracts Awarded, Brooklyn, N. Y.—Two contracts, probably involving total expenditure of close to $175,000, awarded Robins Plant of Todd Shipyards Corporation, Brooklyn, New York. The contracts included reconditioning of the steamships Mexico and City of Savannah.

Construction Contracts, Pittsburgh, Pa.—Dravo Contracting Company, Pittsburgh, Pa., awarded contract by United States District Engineer, Army Building, New York, for construction of steel oil barge for service in New York waters and water barge for service at Philadelphia, with bid of $41,200.

PORT IMPROVEMENTS

Contract Awarded, Seattle, Wash.—Colby Steel & Engineering Company, 416 Central Building, Seattle, Wash., awarded contract by Port of Grays Harbor Commissioner, 206 East Wiskah street, for one 5-ton crane, 95-foot hammerhead crane.

Pier, Cape May, N. J.—W. C. Hunt, 1220 Vine street, Philadelphia, building timber pile pier at Cape May, N. J. Price, $60,000 (timber theatre included). A. J. Sauer, Dencla Building, Philadelphia, engineer.

Dredging Contract, New York.—A contract has been signed between the Mexican Government and American Dredging Company of New York, for deepening and otherwise improving the port of Frontera, in the State of Tabasco, one of the wealthiest ports of the Republic of Mexico.

Grain Elevator, Norfolk, Va.—The contract for construction of Norfolk's new municipal grain elevator awarded to A. M. Crain & Company, of Chicago, whose bid of $639,900 was lowest of six offers, when the time of completion is taken into consideration.

Plans to Deepen Harbor, Gulfport, Miss.—Major Earl North, government engineer in charge of Gulfport, Miss., district, port commissioners of the city of Gulfport, City Attorney Heiss and Mayor Haldon of Gulfport, held important conference recently relative to contemplated improvements of Gulfport harbor and channel. Funds available for dredging this year amount to $175,000, sufficient to dredge channel to 23 feet at mean low tide, making it possible for vessels to go out drawing twenty-five feet. Dredge Pascagoula has commenced work and will be used to deepen channel to municipal pier to make it available to vessels drawing twenty feet. Deepening water for Gulfport, it is believed, will increase shipping.

Piers and Docks, Cleveland, O.—Detroit & Cleveland Navigation Company, foot of East 9th street, Cleveland, O., plans one-story concrete piers and docks, 300 by 700 feet, at $400,000. D. C. McIntyre, manager. Private plans.

Terminal Construction, Memphis, Tenn.—City of Memphis, Tenn., Rowlett Payne, mayor, and Federal Government to construct $500,000 terminals; let contract to R. W. E. Thompson, Earle, Ark., to build 4 concrete floating docks equipped with steel sheds and electric cranes, 1,600 feet tramway extending into the river parallel with the bank. Storage yards and sheds provide facilities for loading and unloading of freight, etc.

Dredging Contract Award, New York.—Port Commissioner of Norfolk, Va., let contract to Atlantic Gulf & Pacific Company, Park Row Building, New York City, for dredging and filling 750,000 cubic yards at Sewells Point, in connection with proposed city terminals.

Contract for Harbor Work, St. Petersburg, Fla.—City let contract to St. Petersburg Concrete Construction Co., 1141 1st street, to construct concrete slab sea wall and dock, part of Bayboro harbor improvements, costing $50,000. E. C. Tarrin, City Engineer.

Harbor Improvements, Miami, Fla.—Bowers Southern Dredging Company, Galveston, Texas, awarded contract by city commissioners to dredge turning basin and slip between docks, $99,060.

Dam, Poplar Bluff, Ark.—Butler County Commissioners contemplating building flood detention dam; approximate cost, $8,000,000.

Dock System, Ohio River.—The Inland Waterways Company formed to build extensive system of docks on Ohio River at Louisville, Kentucky, and Jeffersonville, Indiana. Work opens vast possibilities and is to be started this summer. Interstate Public Service Company to construct the docking system on Indiana side of river and will have charge of operations there.

Development of Oakland Harbor, Cal.—U. S. War Department approved plans for development of Oakland, California, on eastern shore of San Francisco Bay. Estimated expenditure, $1,371,405, part of cost to be borne by City of Oakland and part by Federal Government.

NEW INCORPORATIONS

Los Vecinos Company, Ltd., capital $5,000,000, to operate passenger and freight ships between Los Angeles and Mexican and Central American ports, incorporated in California as a common law trust. President and general manager, John C. Allen; vice-president and assistant general manager, Joseph McMillan; vice-president and secretary-treasurer, E. W. Eidney.

The Western Transportation Company, Wilmington, Delaware, capital $100,000, incorporated at Dover, Delaware, to do business in steamships; Corporation Trust Company of America, at Wilmington, registrars.

The Pennsylvania Shipyards, Wilmington, Delaware, capital $300,000, incorporated at Dover, Delaware.

Delta Export Lumber Corporation, capital $500,000, incorporated at Dover, Delaware, to do an export and import lumber business; incorporators, R. L. Jurden, James E. Stark, and R. G. Hackney, of Memphis, Tenn.

Allen-Jonsen Company, Tampa, Florida, organized by Randolph P. Allen, Carston A. Jonsen and Axsel Pederson; reported to have taken over complete equipment of Daniels Shipyards; plan to build either wood or steel ships of any tonnage.

Union Marine Service Corporation, Fairfield, Maryland, capital $30,000, chartered by Rupert C. Cowles, Charles Hoffman and Frank J. Whelan; to repair ships.

Maryland Dry Dock Company, Fairfield, Maryland, capital $2,000,000, incorporated with John A. Spillman, president; George E. Probst, secretary-treasurer; successors to Globe Shipbuilding & Dry Dock Company; to build ships.

Marine Dispatch Steamship Line, Title Building, Baltimore, Maryland, capital $10,000. Frank B. Ober, Joel W. Massie and Charles B. Hoffman; incorporators.

Dunn-O'Neill Transportation Company, Inc., Clarendon, Va.; Robert O'Neill, president; Harold E. Dunn, secretary.

Kenova Wharf & Ferry Company, Kenova, West Virginia. Organized to establish steam ferry between Kenova, West Virginia, and North Kenova, Ohio.

Inland Waterways Company, Indianapolis, Indiana, build extensive system of docks on the Ohio River at Louisville, Ky., and Jeffersonville, Ind.

Wilbur F. Spice & Co., steamship lines, 300 Chamber of Commerce Building, Baltimore, Maryland, capital $50,000; Robert C. Herd, Henry R. Guttner and Hester R. Spice; incorporators.

"Chilian Lloyd," Valparaiso, Chile, capital $2,000,000, reported to have been founded for the purpose of providing a regular connection with the principal ports of the West Coast. Most of the capital, it is stated, has been subscribed by an important group of merchants who will ship their goods by the new line. The service will be carried on by two 1,800-ton steamers at the outset, which, besides cargo, will be able to carry a small number of passengers.

Argonaut Steamship Company, New York, incorporated under laws of the State of New York, capital $250,000. A. H. Ely, E. P. Collins and H. P. Elliott are reported as incorporators.

FOREIGN ACTIVITIES

Proposed Ports for China.—Negotiations being carried with view to opening Whampoa, China, as commercial port, and plans prepared for harbor capable of accommodating ocean-going vessels. A company has been promoted for purpose of developing Tsingingchow, with a capital of $3,000,000. The company applied to Government for additional $200,000 necessary to finance the undertaking.

New Port of Call, Germany.—The Kroonland, Red Star liner, is to call at Cuxhaven to land passengers. This is first occasion for old Antwerp service to run into this German port.

New Dry Dock, South Wales, England.—Work in connection with construction of new drydock at Swansea by Sir John Jackson, Limited, for Palmers (Swansea) Dry Dock Company is progressing. The Mayor of Swansea made an appeal to Sir John Jackson to give as much work as possible to local men, stating that in anticipation of work non-residents were pouring into the district from all over the country.

Tanker Launched, Belfast.—Messrs. Workman, Clark and Company launched at Belfast the steamer British Engineer, 440 feet long, 6,990 tons, for British Tanker Company's Anglo-Persian oil service. There are ten holds for carriage of oil cargoes, with additional capacity for light oils in tanks built in the 'tween decks.

Port Developments, Argentine.—Report favorable to project of reconstructing wharves and dock at Port of La Plata, Argentina, to accommodate ships drawing up to 30 feet has been made by Communications and Transport Committee of Chamber of Deputies. The scheme is estimated to involve expenditure of over $4,000,000, of which half is included in budget for 1921 and half in that of 1922. New port works at Buenos Aires, being carried out by Messrs. C. H. Walker & Company, under revised contract necessitated by the war, are proceeding satisfactorily. An expenditure of $5,000,000 has been recommended for provision of warehouses and other storage accommodation equipped with electric cranes and cargo handling appliances. Dredging operations are being actively pursued in order to facilitate access to new port, which will receive vessels drawing up to 33 feet.

New Italian Motorships.—Two motorships, one an oil tanker, are being built by Ansaldo San Giorgio for the Roma Steamship Company. Tanker to be of about 8,500 tons deadweight, driven by two Ansaldo two-cycle Diesel engines of 1,100 brake horsepower each, giving speed of 10½ knots on fuel consumption of about 11 tons daily. Steam to be utilized for driving cargo pumps and other auxiliary machinery, although compressed air will be employed for operating steering gear and minor engine-room auxiliaries when the vessel is at sea. The other ship, to be named Faleria, will be of 8,100 tons deadweight, 377 by 51.9 by 24.6 feet draft. Propelling machinery to be similar to that in the ship previously mentioned, and a speed of about 10½ knots is anticipated on an equivalent fuel consumption.

Shipbuilding at Amble, Northumberland Coast.—The Amble Shipbuilding Company, subsidiary of Palmers Iron and Steel Shipbuilding Company, Ltd., Jarrow, has secured an order for building 28 double decked motor boats for service on the Thames. Boats are to order of Thames Motor Boat Passenger Services, Ltd., new company being formed to develop passenger traffic on Thames between Woolwich and probably work higher reaches of the river. They will average 100 feet long, 16 feet beam, and carry 200 passengers each. To be of twin screw type, with Thornycroft engines.

Pittsburgh's Maiden Trip, England.—The new White Star Liner Pittsburgh, 16,600 tons, is due to commence her maiden trip in the company's service from Liverpool and Queenstown to Boston and Philadelphia on June 6. The Pittsburgh is a two-class boat of the Regina type. The ship is equipped with all modern conveniences and luxuries, and her machinery, which is of most up-to-date character, will include six double-ended multitubular cylindrical boilers, total weight being over 650 tons. There are 36 furnaces and 4,764 smoke tubes. The Pittsburgh will work in conjunction with the popular Haverford, a twin screw vessel of 11,635 tons gross register.

Bordeaux and St. Nazaire Improvements, France.—Port authorities at Bordeaux and St. Nazaire planning extensive installation schemes. With approval of Midi and Orleans railways, which are interested, a bill will shortly be tabled in the Chamber to authorize construction of an outer port, to be termed the Port de Verdon, at Bordeaux. St. Nazaire authorities have decided to deepen harbor throughout, building in lower roadstead a new 500-meter wharf, where vessels of 39 foot draft may berth. The mole at Port de Verdon is to be 300 meters long, capable of taking three or four liners at a time. Two new docks are also to be built at St. Nazaire when circumstances make it advisable, one for shipbuilders and the other for incoming liners. Latter to be 800 meters long and 400 meters wide.

Tokio Harbor Developments.—Municipal authorities of Tokio have decided to expend sum of 350,000,000 yen on harbor improvement works.

New Pier at Port Melbourne, Australia.—Harbor Trust Commissioners have adopted proposal to construct a new pier at Port Melbourne, to relieve pressure of traffic on existing pier.

Launching of the Durenda, Port Glasgow, Scotland.—The second motor vessel built to the order of the British India Steam Navigation Company, the Durenda, was launched from the yard of Robert Duncan and Company, Port Glasgow, Scotland, recently. The length is 465 feet over all, beam 58 feet, and the length brake power 450 feet. Two eight-cylinder North British Diesel engines will be installed, with cylinders 26½ inches diameter and 47 inch stroke, having a speed of revolution of 96 per minute. Electric power will be used throughout for auxiliary purposes. Another vessel is being built for the British India Steam Navigation Company with the same dimensions as the Durenda.

BUSINESS NOTES

Metal & Thermit Corporation, New York, announces the removal of its Pittsburgh branch office from 1427 Western avenue, to 801-807 Hillsboro street, Corliss Station, Pittsburgh, Pa.

L. B. Pickering, of Newport News, Va., has been sent to the New York office of the Newport News Shipbuilding and Dry Dock Company to represent the shipyard's repair department there. It is the first time the shipyard has established such an office in New York. Mr. Pickering has been with the shipyard many years. He is a United States Naval Academy man.

The Shipping Board has established seven inland office divisions with Louis F. Klein of New York as manager. One of the most important offices will be in Chicago. The other interior offices will be at Detroit, Minneapolis, St. Louis, Memphis, Kansas City and Cincinnati.

STEAMSHIP INTERESTS

Announcement has been made by the M. H. Tracy & Company, New York, of a fortnightly intercoastal service, the first sailing to be June 1. It is reported that the company may include in their list of direct ports of call on the Pacific coast, those ports recently eliminated by the westbound conference, among which were San Diego and Tacoma.

The Ward Line inaugurated on May 18 a passenger and freight service between Tampico, Vera Cruz and New Orleans. Every two weeks the *Yucatan* will leave New Orleans. The ship will go to Tampico via Vera Cruz but will go direct from Tampico to New Orleans on the return trip.

Two additional river steamers have been purchased by the Buxton Line, Norfolk, Va., and service between Norfolk and Richmond will be put on a daily basis. There has been no daily service on the James River since the former Old Dominion Steamship Company abandoned the line two years ago.

Announcement has been made by the Isthmian Steamship Lines, Inc., New York, of a regular service between New York and ports of South and East Africa, beginning with the steamer *Birmingham City* sailing on June 20 for Cape Town, Algoa Bay, East London, Port Natal, Delagoa Bay and Beira.

Starting with the sailing of the steamer *Taiyo Maru* May 11, the Toyo Kisen Kaisha inaugurated a new route for its steamers from San Francisco to the Orient by way of Formosa, allowing the passengers a day stop over at this port. The company's freight steamers making tours of the world will make calls at Australian ports hereafter, thus inaugurating the first Japanese service route via Australia.

With the sailing of the steamship *El Mar*, formerly of the Morgan Line, from pier 27, North River, New York, a direct freight service between Portland, Maine, and New York was resumed May 22. The Portland and New York Steamship Company expects to maintain bi-weekly sailings from each port. The company is offering freight rates lower than those for rail hauls between the two ports. Other ships will be added as the cargoes offered warrant the increase.

General Pacific coast agents for the American-Hawaiian Line, New York, have announced that the westbound sailings of the steamers of the line will be increased from a fourteen-day schedule to a weekly basis.

With the steamer *North Star* inaugurating a system of lakes-rail-ocean communication, the northwest was brought nearer to Europe with the arrival of the ship at Chicago. The vessel is one of 24 steamers connecting Buffalo, Erie and Detroit with the terminals of western roads at the west of the lakes. The fleet will accept export bills of lading from any interior points with railway connection to Chicago for shipment to Liverpool, and other European ports via the Lehigh railway from the east ports of the lakes to New York and ocean steamship lines the rest of the way. Opening of the lakes-rail-ocean traffic has made possible rates ranging less than corresponding rail rates for shipments to or from the interior, according to company officials.

The New York & Porto Rico Steamship Line has reduced its passenger fares between New York and ports of Porto Rico. The company's sixteen-day cruise around the island, which for years has been a popular vacation feature, is reduced from $180 to $150 for minimum accommodations and the one-way fare from New York to San Juan is now $65 instead of $75. These reductions are permanent.

The Portland & New York Steamship Company has inaugurated a direct freight service between New York and Maine. This service was very much used by shippers and receivers for many years prior to its discontinuance in 1917.

TRADE PUBLICATIONS

Electric Rivet and Metal Heaters.—The story of the development and application of Berwick electric rivet heaters is contained in a well illustrated catalogue which the American Car and Foundry Company, New York, has recently published. Since 1912 the company has been experimenting with devices for heating rivets electrically and in November, 1919, machines for this purpose were perfected. Complete details of the various types and capacity heaters are given with comments from railroads, boiler shops and other shops where the heaters are used. Information is given on automatic heaters which are now being developed for heating bolt blanks, drop forgings, bar stock 20 to 30 feet in length of any cross sectional area from 3/8 inch diameter up to 1½ inches, for spot welding and the like. The company is also interested in developing electric heaters for practically any special requirement and will be glad to supply the catalogue on request.

Boiler Tube Thimbles.—A folder describing the method of installing boiler tube protection thimbles has recently been sent out by the American Boiler Tube Thimble Company, Providence, R. I.

Copper and Brass.—The April bulletin of the Research Association of the Copper and Brass Industry, New York, contains information on the relative merits of copper and aluminum electric conductors. The subject of brass hardware and the use of brass pipe are taken up in detail.

Forty Years of Progress.—The history of the forty years' growth of the Heine Boiler Company, St. Louis, Mo., and the announcement of the change of name from the Heine Safety Boiler Company and of the new control are given in a bulletin just sent out by the company. Various types of Heine boilers are also briefly described. It is the purpose of the company to extend the assistance of its facilities and engineering service to all those who design, erect and operate power plants in which Heine boilers are used.

WE GUARANTEE that of this issue 5,450 copies were printed; that of these copies 3,964 were mailed to regular paid subscribers, 346 were provided for counter and news company sales, 212 were mailed to advertisers, 29 were mailed to employees and correspondents and 899 were provided for new subscriptions, copies lost in the mail and office use; that the total copies printed this year to date were 38,450—an average of 5,493 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers. Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

"To Be Or Not To Be?"

THE time for Congress to answer the merchant marine question yes or no has arrived. It must soon divulge whether or not it meant what it said in the preamble of the Merchant Marine Act of 1922 when it declared that it was the policy of the United States to develop an American merchant marine, under private ownership, adequate in size to meet our commercial needs in time of peace and to serve as a naval auxiliary in time of war, and that it, Congress, would do everything possible to attain this end. What are the indications?

The subsidy bill was introduced in the House by George W. Edmonds on June 14 and then referred to the Committee on Merchant Marine and Fisheries. This committee favorably reported the bill back to the House on June 16, the vote being 9 to 4. While such prompt action is not an assurance that the House will pass this legislation, nevertheless, it is a strong indication, when a committee, which has given careful study to a measure is so overwhelmingly in favor of it, that the necessity for its enactment into law will be just as apparent to Congress as a whole when it gets the opportunity to analyze and discuss the merits of the act.

Necessity alone, however, is not a sufficient reason, we are sorry to say, for anyone to expect favorable action from Congress. There must be a strong demand backed by the public opinion which in the last analysis is the real government of every civilized nation in the world today.

From no one is this demand more insistent than from our "first citizen," President Harding. True to his pre-election pledge, he has caused to be conducted one of the most complete and exhaustive studies on the shipping situation ever made. In this investigation the best known specialists in the marine field were called into consultation irrespective of their political affiliations. He has taken their facts and findings and presented them to Congress in a special message. He now demands that Congress take action on the shipping bill during the present session and should such action not be forthcoming, he has declared that he will exercise his prerogative and call a special session of Congress solely to consider this measure so vital to our merchant marine.

Following the lead of the President, by far the largest number of influential newspapers have expressed themselves editorially in favor of the subsidy. In a canvass of 300 of the leading papers the National Merchant Marine Association reports that over 70 percent favor this measure. The shipping bill is not only receiving a large amount of editorial comment but it is also obtaining a tremendous amount of publicity in the news columns. Who ever saw so much space devoted to shipping legislation before? Front page stories and feature articles particularly in the newspapers of the interior are the strongest indication that the farmer, the manufacturer, the business man and the working man recognize that the American merchant marine will benefit themselves as well as those who live on the seacoast.

The endorsements that the subsidy bill has received from trade organizations, commercial bodies and chambers of commerce from all over the country and representing every phase of industry—agriculture, mining, manufacturing and business—ought to convince Congress and are in fact one of the best indications that the time for action is not to be deferred. The opponents of the bill are playing for time, knowing full well that they cannot defeat it, if action is taken now. Foreign propaganda and stubborness, however, will not avail; it is now or never for our merchant marine and it is going to be now.

Speaking of Discrimination

IN view of the apprehension that has been expressed by some of the opponents of the pending Shipping Bill that many of its provisions would offend other countries and thus invite retaliation, it is interesting to note the inducements that Canada offers to American manufacturers to establish branches in that country.

According to the Shipping and Exporting Register of Canada, Canadian-made goods get preferential advantages in British Empire countries as well as the benefit of trade agreement with certain foreign countries. Great Britain grants a rebate of one-third duty on certain articles, including motor cars, musical instruments, clock and cinematograph films, and one-sixth duty off numerous other articles. Mr. Lloyd George states that as articles are added to the tariff, preference will be extended to British Empire countries. The subject is listed for the next Imperial Conference.

"British Colonies in the West Indies, British Honduras, British Guiana and Central America give Canada a preference ranging from 10 to 50 percent. New Zealand imposes a surtax on goods from non-British countries averaging 12½ percent as well as a preference of about 10 percent. Cyprus gives one-third off on certain goods and one-sixth off on a large list of articles. Australia, Hong Kong and Shanghai are traditionally fore-disposed to trade with British Empire countries and have preferential measures under consideration."

The above list contains governmental regulations only. The preference given to British shipping by combinations of British banking and commercial organizations similar to that which caused the recent Egyptian cotton controversy are still more effective. Rebates have been in vogue for years. We will never have a merchant marine of our own until Congress grants sufficient protection to meet our competitors "on all fours."

Prohibition On The High Seas

The question of whether or not liquor shall be sold on American vessels outside of the three-mile limit is one thing, but an agitation on the matter started by the executives of the Anheuser-Busch Brewing Company at a time nicely calculated to embarrass the pending shipping legislation is quite another.

We do not believe that the Messrs. Busch were actuated by any desire to aid the cause of prohibition or American shipping. On the contrary, it looks very much as though they hoped to start something that would eventually result in a modification of our laws so that they could resume their erstwhile business of the manufacture and sale of lager beer in this country.

They must know that, if American passenger ships are forbidden to serve liquors, it will not make the seas any drier. The only effect will be to drive prospective travelers to take passage in ships flying foreign flags. This means not only the citizens of other countries who are accustomed to the daily use of wine and liquor but also a large percentage of American travelers as well.

The Shipping Board has taken the ground that the eighteenth amendment does not apply to American ships outside of the three-mile limit. This decision is largely based on rulings of the Supreme Court to the effect that American ships are not a part of the territory of the United States except in a figurative sense. "Seamen employed on them cannot be said to be working in the United States. They are subject to the jurisdiction of local authorities in foreign waters for the punishment of crimes committed on board in such waters. Neutral merchant ships may be seized on the high seas and condemned by belligerents for carrying contraband of war. They may be seized, attached and sold under process in rem for claims in tort, or for debt in our own or in a foreign country. Political refugees may be removed from them when they are in foreign waters."

The above reasons ought to be sufficient to justify the Shipping Board in refusing to forbid the sale of liquor on American ships outside of the three mile limit but there is a grave danger that a bill will be introduced which will clearly put our ships under the restriction of the Volstead Act. But, if Congress feels that it is necessary or desirable to do this, it should make the law read that no merchant vessels whether *foreign* or domestic upon which intoxicating liquors are sold shall enter the ports of the United States, for in no other way can they prevent those who travel to and from our shores from obtaining all the booze they want en voyage.

A Dangerous Opponent

The *New York Journal of Commerce* which recently issued a Shipping Supplement with the aid of and in conjunction with the *Manchester Guardian* (England) and whose revenue is largely derived from the advertisements of foreign shipping companies is trying its darndest to defeat the Shipping Bill or at least delay action on that measure until our merchant marine is as dead as the proverbial door nail.

In an editorial appearing in its issue of June 5 entitled "Subsidies and Treaties"—what subsidies have to do with treaties, by the way, is not explained—it says "competent men" (foreign or American?) "engaged in the shipping business assert that there is no reason why well managed American vessels cannot compete without subsidies and in fact we have at times carried as much as 50 percent of our foreign trade in our own bottoms."

When a daily newspaper, published in our greatest seaport and devoted to the commercial business and knowing full well that we have not had a privately owned merchant marine worthy of the name for seventy years makes a statement like this it is high time that its American patrons should question the sincerity of its often expressed solicitude for the welfare of our shipping.

The Shipping Board at the recent hearings furnished statistics showing that but 5 percent of our overseas commerce was then being carried in privately owned American bottoms and the *Journal of Commerce* in bringing up as a criterion a short period of time after the war when anything that could stay afloat could secure a cargo at an abnormally high freight rate is certainly not trying to present a true picture of the actual situation.

The very title of the editorial "Subsidies and Treaties" is bound to create the impression that we cannot assist our ships financially without breaking our diplomatic obligations. Having got this thought in the headline, which is as far as many of its readers go, it states in the middle of the editorial that "cool headed foreign competitors recognize that they have no basis for complaint, if the United States chooses to empty its Treasury into the pockets of shipowners."

One would think that some concern would be expressed at

the present drain on the Treasury which will continue as long as the Shipping Board is unable to dispose of its vessels, but on this subject it is silent.

The editorial, however, does give us an (encouraging?) suggestion. It says that there are no worse discriminations against American shipping than those that are practiced by some British territories. And, if we will only forego the indirect aids proposed in the Shipping Bill and devote our energies to requesting the stoppage of these discriminations, there is no doubt that we could obtain their abolition in a short time.

This sounds fine, but our legislators had similar information very much in mind when they framed Sections 28 and 34 of the Jones Act. Is it to be expected that foreign countries would be impressed with a promise not to enact legislation when for over two years discriminatory laws have been inoperative on our statute books?

Foreign Shipping Investments

EVER since Commodore Vanderbilt withdrew his money from shipping to invest it in railroads, giving as an explanation that he would rather make 6 percent than 3, it has been very difficult to interest capital in steamships flying the American flag.

Of course, the rapid developments that have taken place in the interior and western portions of this country have given many opportunities for secure investments at large profits; nevertheless, we have financed one of the greatest steamship companies in the world, namely, the International Mercantile Marine Company which has about 90 percent of its vessels registered under foreign flags. The fact that 93.5 percent of the stock in this company is American owned, according to a sworn statement made before the Shipping Board last October, is ample proof that our investors are not adverse to putting their money into the steamship business providing they can be convinced that it can be operated on a sound and profitable basis.

Over twenty years ago, when the International Mercantile Marine Company was formed, it was a wise and farsighted policy to purchase the finest ocean liners in the world, even though they were under foreign flags. The transaction met with general approval in this country and general disapproval in England, which was so intense in that country that the *Lusitania* and *Mauretania* were practically presented to the Cunard Line.

Many advantages have come from this transaction, not the least of which is the experience gained in steamship operation. The past is past but what can we say now to justify ourselves to future generations at the spectacle, when private capital is so urgently needed to purchase and operate American ships, of foreign steamship companies that are unable to raise money in their own country coming over here and floating their securities with apparent ease?

Only this spring we invested $7,360,000 in 25 year 6 percent bonds of the Holland-America Line which that company declared was desired for the purpose of new steamship construction. In May we invested $5,000,000 in 15 year 6 percent bonds of the Scandinavian American Line, which were heavily oversubscribed in one day. Both of these companies are competitors of American shipping and still we aid them to build the very type of vessels that we so urgently need to balance our fleet for commercial purposes and to prevent the 5-5-3 naval ratio from becoming a joke as far as naval auxiliaries are concerned.

In view of this, how can anyone say that shipping would not be an attractive investment to the American public provided it receives the proper Government aid? And, of far more importance, how can anyone say that American shipping does not need protection when foreign steamship lines can easily obtain all of our money that they want while the Shipping Board is finding it most difficult to sell either its ships or its securities and American shipping loans are almost impossible to float?

Agamemnon and Mount Vernon

THERE is no one more aware of our lack of fast passenger ships than the chairman of the Shipping Board. It is largely due to his efforts that the *Leviathan* is now being reconditioned into the finest ship afloat. When finished, however, she will be the only liner that we will have in service capable of maintaining a sustained sea speed of 22 knots or over.

One ship alone cannot maintain an efficient express passenger service and it will therefore be necessary either to match the *Leviathan* with some such ship as the *Columbus* of the North German Lloyd Line or to recondition the *Agamemnon* and *Mount Vernon*. Each of these two ships is capable of making 22 knots or better and they can be fitted out for about $2,500,000 apiece in eight months' time in any of our well equipped shipyards.

In the January issue of Marine Engineering and Shipping Age, we published an article analyzing the economic possibilities of these two ships and there were several well known shipping men at that time who favored reconditioning the *Agamemnon* and *Mount Vernon* in preference to the *Leviathan*.

It was pointed out, however, that the Shipping Board expected to be in a much stronger financial position on the first of July, which is apparently the case, and it was hoped that the President's plan for aiding the development of our merchant marine would be in force. Therefore, we did not feel that it was a case of the *Leviathan* versus the *Agamemnon* and *Mount Vernon* but simply the *Leviathan* first and the other two following.

These two ships are still lying at their dock. So far as we know there has been no definite policy in regard to their disposition adopted, although it is reported that they are about due for serious consideration. We cannot sell them to a foreign company for they would be immediately fitted out and placed in competition with our own vessels and, if it would pay a foreign company to do this, why should we hesitate?

It is not necessary to recondition these vessels in as luxurious a manner as the *Leviathan*. If they are provided with a standard of passenger accommodations equal to those in the *George Washington* or are based on what a conservative steamship owner would spend under like conditions, they will make a very satisfactory addition to our fleet.

The Close of the Battle for Independence on the Seas

Claims of the Opponents of the Ship Subsidy Bill Prove Groundless—Facts and Patriotism Will Win the Fight

By "Old Scotch"

FROM time immemorial a country's shipping has been considered the ward of the nation. It is unlike every other kind of national industry, in that it must necessarily be conducted away from home. If it thrives without direct or indirect aid, all well and good but, if any maritime nation finds that its shipping engaged in transacting its overseas trade cannot be self-sustaining, the business of that nation will not succeed unless its undivided support is given to maintaining sufficient ships to conduct its just proportion of foreign trade.

These economic facts have gradually sunk into the minds of the American people. The long hearings conducted by the joint Congressional committee on the pending subsidy bill have not brought out much that was not already known concerning our shipping situation and, as a whole, the results may be summed up as giving conclusive evidence that national assistance must be given to our ships or they cannot compete with their foreign rivals.

Opponents' Claim Highly Fallacious

A weak effort has been made to prove that our fleet, having a greater proportion of oil-burning vessels than that of any other nation, must necessarily have, on that account, sufficient advantage to overcome the other differentials in cost. In the days of relatively high cost of coal and low cost of oil, there might have been some grounds for such a contention. Now, however, the claim is highly fallacious, as those of us who are familiar with existing and probable future conditions are quite confident that in steam vessels there will probably be a number of conversions from oil burning to coal burning in the not distant future.

The burning of oil for steam production on land or sea is even now against economic conditions, when we take into consideration the limited known supplies of oil and the enormous annual increases of consumption of gasoline and other motor fuels. In the writer's opinion, another decade will see a great diminution in the number of oil-fired steamers and a great increase in motor driven vessels. With our dwindling supplies of oil, there can be no question as to the substitution of motive power which uses only one-third of a pound per horsepower hour for steam machinery which, at the best, uses one pound of oil per horsepower hour.

Fuel Issue Failed Dismally

So, we may as well dismiss the idea that American merchant vessels have any advantage over foreign fleets, because of the larger use of oil as fuel. On the contrary, because of our lack of progress in the adoption of Diesel engined vessels we are at a decided disadvantage with other nations, if we consider the fuel costs of operation.

This matter of fuel seems to have been the main issue raised by the opponents of the subsidy bill, and in that they have failed dismally. There remains no outstanding feature of the opposition to which any credence can be given by those inclined to vote against the pending bill.

A Mild Attack of "Buck Fever"

At this stage of the proceeding, the friends of the measure are going through a mild attack of what is known as "buck fever." That is entirely human and occurs to everybody who attempts to do anything out of the ordinary, which requires fortitude and persistency. We who advocate the measure are convinced that we are right and that it is a just bill, warranted by every condition which goes to make us a happy and prosperous nation. Why then become alarmed because of the various press stories which emanate from Washington as to the "grave doubts entertained by Congressional leaders" as to the ultimate passage of the bill?

True it is that members of the Senate and House who must come up for re-election in November next are apprehensive of every action they take in regard to the important bills now being considered by Congress. They always are at this stage of the proceedings, so far as that is concerned. In the matter of the ship subsidy bill they need have no alarm, if they vote for it; rather they should have some fears, if they vote against it.

The American people far and wide have been well educated on this subject in the past five years. It is naturally very difficult to gage public opinion in a vast country like ours, the only logical method being to appraise the editorial policy of the leading newspapers, as our public press taken on the whole both molds and reflects public opinion on great national subjects. It would be valueless to the average Senator or Congressman to know that the majority of papers in New York and San Francisco favored the subsidy bill, as the answer is that, being important seaports, they quite naturally would favor anything of benefit to shipping. The National Merchant Marine Association, with its headquarters at Washington, has recently performed a very valuable service towards ascertaining what the general sentiment of the country at large is towards this bill.

Press and Commercial Bodies in Favor of Subsidy Bill

Their poll covers the leading newspapers published in 43 different states. These papers, 300 in number, represent all shades of political affiliations, and it is most encouraging to learn that of that number 193 have expressed themselves unqualifiedly in favor of the subsidy bill, 77 were against and 30 were non-committal. Therefore, over 70 percent of the leading journals throughout the country are on record as favoring the passage of the bill.

Another barometer, second only to the public press, is the attitude of the leading commercial organizations throughout the country. These have, with but a very limited number of objections, gone on record as heartily in favor of the proposed direct and indirect aids. The United States Chamber of Commerce, representing commercial organizations throughout the entire land, at its recent national convention announced itself in favor of establishing and maintaining a merchant marine "of a capacity sufficient to transport at least 60 percent of the cargoes entering into American overseas commerce," which is exactly what is aimed at in the Jones-Greene bill. A special committee of the Chamber, composed of leading business men, after making an exhaustive inquiry into the subject, concluded its recommendations with the very logical statement that "To surmount the difficulties that lie before us will require time, patience, perseverance and the free exercise of those other qualities that have in other fields of endeavor led the American people to success. The committee doubts neither the results nor the justification of all the effort required to attain it."

Apprehension as to Passage of Bill Groundless

Backed as the measure is by the press, the great commercial organizations and an aroused public sentiment, we should

enter the close of the fight, when definite action is to be taken, without apprehension as to the ultimate results. "Let the heathen rage," the heathen being in this case those who are against our having a merchant marine for their own sinister self-interests. There is no occasion for the "buck fever," which seems to have seized some of the friends of the bill. During the recent centennial anniversary of the birthday of General Grant, many anecdotes were printed concerning that great military leader's life and acts. None was more interesting than one quoted from the General's own memoirs, and which is particularly applicable to present moment contemplation of the forthcoming battle in Congress.

It seems that young Grant had no fears at all in the many one-sided engagements in which he participated during the Mexican war. In his more mature years, after being placed in command of the Union troops about to begin fighting in Missouri, he proceeded to attack a strong Confederate position in the central part of the state. Upon approaching within four or five miles of where the battle should take place, the General admits that he was seized with a great feeling of apprehension, almost approaching cowardly fear. Being in command, he realized that it would not do for him, of all men, to show the white feather, so summoning all his will power he ordered the advance on the enemy. Arriving at the place where the opponents were supposed to open fire, he found that during the preceding night the enemy had decamped bag and baggage. "Then and there, I determined," said the General, "that the other fellow was even more scared than I was." So ever after that, throughout all his battles, the element of fear never entered his calculations.

While it is not expected that the enemy will fold up their tents and decamp, at the approaching subsidy battle in Congress, there is nothing for us to fear as to the result. After their "hot air barrage" of general debate on the bill has been exhausted, it will be found that the enemy has no heavy guns to bring into action. They are lacking in the ammunition of facts and patriotism, which are the essentials of winning a battle of this kind.

American Farmers and American Ships

Both the Farmers and Their Soldier Sons Recognize Folly of Depending on Foreign Nations for Ocean Transport

By Winthrop L. Marvin*

MOST of the farmers of this country—and particularly those farmers whose domiciles are between the Ohio River and the Rocky Mountains—do not dream of the conspicuous part which they have been playing this year in sundry European journals devoted to commerce and finance. When the United States Shipping Board last autumn began to prepare information for use in the lining out of a constructive National shipping policy, the editors of the transatlantic mercantile press instantly sat up and took notice. They began straightway to wonder and conjecture what the new American shipping legislation would be like, and when President Harding, with definite proposals at hand, made his eloquent appeal to Congress for an American merchant marine competent to serve the country in either peace or war, a very unmistakable agitation appeared among those overseas interests that had been monopolizing for many years nine-tenths of the ocean carrying trade of the American people.

They did not relish this demonstration that the Americans were preparing to "consolidate" an independent merchant shipping position of their own. The journals of European commerce confessed a fear of the consequences of President Harding's proposal that 50 percent of the immigrant traffic into the ports of the United States should be conveyed in American passenger vessels, or the plan for a deduction from the Federal income taxes of shippers of 5 percent of the freight moneys paid on goods transported in American ships. An American building fund for the encouragement of shipping, it was felt, might have something of the same results as the fund from the British treasury which built the *Mauretania* and *Lusitania*. And finally there was undeniable danger to European dreams of continued maritime monopoly in the mail subventions to fast liners and the subsidies or "compensation" to cargo ships of the United States engaged in international commerce.

Creates Consternation Abroad

There was almost a panic in maritime circles abroad when the National shipping bill was introduced. It was so unexpectedly far-reaching, so ingenious, so "adroit." Moreover, there was such a quick and formidable response to the appeal of the President from American manufacturers, merchants and bankers.

But those who presided over the destinies of the organs of European commercial and maritime interests found one consolation in the thought or hope that President Harding's constructive shipping program would be opposed and might be defeated by "the Western farmers" and "the Democratic party." These two influences were eagerly invoked in the European press as the faithful and sure protectors of European interests. In all of which those wiseacres who were commenting on the American shipping legislation overseas showed that they were not entirely acquainted with either the farmers or the Democratic party. There are a great many good Democratic citizens in this country of ours who want to see an American merchant marine and naval reserve just as earnestly as any Republican followers of President Harding. There are also hundreds of thousands of American farmers who have understood the problem of the merchant marine and have held the same convictions about it as have their salt water fellow countrymen.

It is a mistake to assume, as not only these European editors and statesmen but even some onlookers in this country have been doing, that "the farmers" are necessarily opposed to National aid for American ships. Many farmers are opposed, without question. But the curious observer who will turn back to the files of the *Congressional Record* from 1900 to 1908 and thereabouts, when the Frye-Hanna and Gallinger shipping bills were under consideration, will discover that the majority of the senators and representatives in Congress from the Middle West, or at least the majority of those of the Republican persuasion, spoke and voted for the constructive shipping policies of McKinley and Roosevelt. It was only a minority of those senators and representatives who were against the policies—but this minority, combined with the almost solid Democratic opposition of the time, was able to turn the scale against American shipping legislation by a narrow margin of from three to seven in the House of Representatives.

*Vice-president and general manager of the American Steamship Owners' Association, New York.

The farmers of America, taking them as a whole, are not less intelligent or less patriotic or less far-sighted than other Americans. The great majority of our farmers live far from the sea. With the building and handling of ocean ships they are not acquainted. But they are also reading men and thinking men in the same degree as other great classes of our citizens, and the specious plea of European ship monopolists that foreigners be allowed to carry our ocean trade because they can do it "more cheaply" has not deceived all of these farmers by any means, or even at any time a majority of them.

In the recent hearings on the Shipping Bill before Congress, what is regarded as the soundest and strongest of the farmers' distinctive organizations, while not enamored of the word "subsidy," came out through its chief executive for the passage of the Harding Shipping Bill. There are particular reasons, and very strong compelling reasons, why the farmers of the country at large, North and South, have a great deal at stake in the development of an adequate merchant marine. In grain, cotton, provisions and some other things, American farmers have a considerable surplus of products beyond the consuming power of America herself. These goods must be exported, in order that the farmers may realize proper compensation for their labors. For the export of these surplus products ocean ships, operated on dependable, regular schedules, are essential, and for the fullest protection of the farmers' interests these ships must be built, owned and controlled in the United States, so that they may be available in peace or war to serve "America first."

Scarcity of Ships Remembered

This is exactly what the American farmers did not have in 1914. On the contrary, it was the ships of Great Britain, Germany, France, Italy and Japan that were then carrying all but a small fraction of our ocean commerce. What happened on the outbreak of the war is keenly remembered. The German ships, of course, were immediately captured or laid up. Those British ships which the British government required for war purposes were immediately ordered home. So were the ships of France and later of Japan and Italy. Then there came to the American farmers—to the growers of wheat and growers of cotton—a sharp realizing sense of the essential humbug of the proposition, "Let foreigners carry our trade—they can do it so cheaply!"

Instead of "cheap," this infatuated dependence on foreigners instantly became exceedingly dear. Because there were so few foreign ships left in our commerce, and because only a handful of American ships were available, freight rates on the export of our wheat and cotton to Europe were straightway raised to an unheard-of altitude. In July of 1914, a month before the outbreak of the war, the freight rate on grain from New York to the United Kingdom was four or five cents a bushel. By December, 1914, this freight rate had advanced to 16 or 17 cents a bushel—an increase of about 300 percent. To the Continental port of Rotterdam before the war the freight rate on grain from New York had been 6¼ cents a bushel. In December, 1914, it had reached 30¾ cents a bushel—an increase of about 400 percent. So with cotton. Most Southern senators and representatives before the war had voted doggedly against any National aid or encouragement to the merchant marine. They were very severe in their strictures on the "subsidists." They were fond of arguing as a whole that foreigners ought to be allowed to transport our cotton because they could do it "so cheaply!"

The freight rate on cotton from New York to Liverpool before the war was 20 cents a hundred. In December, 1914, it was 75 cents a hundred. The freight rates on cotton from the Gulf to Rotterdam, like the freight rates on grain, had increased 400 percent.

And this was not the end; it was only the beginning. Month after month, as the folly of dependence on foreigners for ocean shipping bit more and more deeply into the consciousness of the American people, freight rates on grain and cotton to Europe, still dominated as they had been before the war by alien interests, kept on increasing by leaps and bounds—and the Democratic Secretary of the Treasury in the cabinet of President Wilson was proclaiming to the country that dependence on Europe for the sea transportation of our products was a policy that was costing the American people many hundreds of millions of dollars a year!

Heavy Toll Exacted by Foreign Steamship Owners

"From every Atlantic and Gulf port," declared Secretary McAdoo to an audience* in the city of Chicago, "there comes the cry of scarcity of ships and exorbitant rates. These enormous increases in rates," Mr. McAdoo added, "constitute a heavy tax on the American producer. They are reflected in the lessened prices which he has been compelled to take for his product. The increased cost of carrying American produce and commodities to European ports since the war broke out runs into millions." And he added impressively, "This great sum represents a heavy toll that has been exacted by foreign steamship owners from American shippers and producers. It is in effect a penalty they are paying for the failure of American politicians to carry out their repeated promises to the American people. Foreign owners may increase their rates overnight arbitrarily—we have no power to prevent it—and we must pay the price or stop our shipments!"

Secretary McAdoo, a fervent Democrat and a red-blooded American, placed the blame right where it belonged—on the avaricious "foreign steamship owners" and on the American politicians who had failed "to carry out their repeated promises to the American people."

Because it was the farmers of the West and of the South who had the bulkiest products for export—products which absolutely had to be shipped abroad—it was these Western and Southern farmers who were the heaviest sufferers from the lack of an adequate American merchant marine.

To say that these farmers have forgotten their experience of 1914-1918, and that they now have no interest in American ships, is to accuse them of a lack of intelligence of which they are emphatically not guilty. They remember—and their soldier sons remember. For when in self-defence the United States herself entered the world war, and it became necessary for our nation to find ships to send its own boys overseas, the poverty of the American merchant marine and the unconscionable folly of depending on foreign nations for ocean transport in peace or war became even more astounding than before. Because there were so few American ocean passenger steamers it was necessary for the government hurriedly to fit cargo steamers of relatively low speed and to improvise all kinds of transport craft, with the result of an immensely increased hazard of destruction by the German submarines. And to make matters still worse, when the painful scenes that accompanied the torpedoing of the *Antilles* and the *Finland*—the rush of panic-stricken foreign seamen to the boats, leaving the soldiers and the sick behind—compelled the Navy Department to issue a command that all merchant transports should be manned by the 100 percent Americans of the Navy, there had to be ordered to these transports raw sailor recruits from the prairies and the cotton fields who had never seen a ship before they donned the blue, and, of course, were totally without experience as seamen.

Somehow—thanks to the too-small trained personnel of the regular Navy—we did manage to muddle through and get the boys across. But the awful peril of that situation is not yet forgotten, and never will be forgotten by the American people. Hundreds of thousands of young Western and Southern soldiers and seamen who traveled the road to

*Address of Hon. William G. McAdoo before the Commercial Club of Chicago, January 9, 1915.

Revised Ship Subsidy Bill Analyzed

Member of Merchant Marine and Fisheries Committee Explains Features of Bill as Reported to the House

By Congressman George W. Edmonds

I AM naturally proud of the work of my sub-committee. This bill, together with the Shipping Bill, 1916, and the Merchant Marine Act, 1920, will make a record of constructive legislation upon a comparatively new subject to the present generation of Americans, which any legislative body could well point to with pride. This bill has required the best that can be collected from the brains of men in many callings, and collectively, if passed by Congress, will mean that 50 or 60 percent of our foreign commerce will be again traveling the seas under the American flag. I say collectively because each section of the proposed bill is interwoven with the other, each having its own particular aid to give, and particular performance to bring into action.

As a whole it is like a house of stone and while made up of many blocks, joined together by proper cement, the completed structure will give the required result. The bill as compared with the bill introduced on February 28, contains the following important changes:

Title I—Section 1

The section in regard to the sale of the vessels has been amended so as to read:

"Public or private competitive sale," also interest on unpaid purchase price has been increased to 4 percent from 2 percent.

Also the following has been added:

"The payments of principal shall be so arranged that the amounts due or paid under the contract of sale as principal up to any moment of time shall be sufficient to cover depreciation of the vessel up to such moment."

Title I—Section 2

New Section 2 provides that in selling the vessels the board should be careful to encourage present lines, particularly those operated by residents of particular communities, so that they may arrange to purchase the ships. It further prohibits the board from selling such vessels to persons outside of the domestic communities for a period of two years, so as to give them every opportunity to consummate their purchase.

Monopoly of ships or ports is declared against the policy of the Congress.

Title I—Section 3

There has been virtually no change in the construction fund except that it has been made explicit that this is a revolving fund; the amount remains at $125,000,000 and the interest not less than 2 percent.

Subsidy Bill Postponed a Month

President Harding informally sanctioned on June 20 a postponement of consideration of the ship subsidy bill in the House for approximately a month, so that Congressmen may have an opportunity to visit their districts and discuss the bill with their constituents. The President regards the plans for establishing an American merchant marine as a big American problem and he wants the people to understand it. "The plan is unfailing in its appeal to the sober judgment of the American people," the President said.

The President still feels that it is most vital to have the question settled at this session of Congress and he will, therefore, continue to insist that Congress express itself definitely before adjourning. If this is not done, the President will carry out his announced plan to call an extra session this summer.—The Editor.

Title II—Section 201

The taxation features in the new bill remain virtually the same. The construction tax deductions are the same as in the Merchant Marine Act, 1920. Only the administrative features have been made more explicit, so that there can be no question of doubt of their operating successfully.

Title II—Section 272

The depreciation feature of the taxation provision of the bill has been explicitly stated so that the depreciation arising out of war conditions can be spread over five years. This will assist in helping out the extraordinary losses in shipping property.

Title II—Section 273

The section containing the 5 percent deduction for shippers on freight paid in American vessels and applicable to their income taxes remains in the bill, the provisions being fully written out in the bill. The doubling of tonnage taxes as provided in the bill are retained in the new bill, excepting that they are not doubled upon power vessels of under 1,500 tons, or sailing vessels of under 1,000 tons, it being contended that these vessels being not subject to compensation should not have the extra tonnage tax to pay.

Owing to treaty obligations there has been a new immigration section placed in the bill. It reads as follows:

Title III—Sections 301 to 304 Inclusive

"Sec. 301. As nearly as practicable one-half of the total number of immigrants, admitted to the United States in any fiscal year, shall be transported in vessels registered, or enrolled and licensed, under the laws of the United States."

"Sec. 302. The Commissioner-General of Immigration with the approval of the Secretary of Labor shall make regulations necessary for the enforcement of Section 301. All such regulations, insofar as they relate to the administration of such section by diplomatic or consular officers of the United States, shall be subject to the approval of the Secretary of State."

"Sec. 303. Section 301 shall not take effect as to immigrants transported in a vessel documented under the laws of any foreign country until a time fixed by proclamation of the President. The President is authorized and directed, whenever in his opinion the provisions of this title or of regulations made thereunder, are or may be in conflict with treaties or conventions with a foreign country, to take such steps as may, in his opinion, be necessary to remove such conflict. Whenever, in his opinion, no such conflict exists

in the case of any country he shall proclaim, and the provisions of this title and regulations made thereunder shall take effect in the case of immigrants transported in vessels documented under the laws of such country at the time specified in the proclamation therefor."

"Sec. 304. The term 'United States' as used in this title in a geographical sense means the several States, the Territories of Alaska and Hawaii, the District of Columbia, Porto Rico, and the Virgin Islands."

The Naval Reserve section has been dropped in the new bill.

Title IV—Section 402

There has been no change in the sources of the fund for compensation:

1. All tonnage taxes and light money.
2. Ten percent of the customs duties.
3. Compensation for first, second and third-class mails.
4. Any amounts returned by the limitation of profits clause.

Title IV—Section 403

Contracts for compensation are limited to 10 years.

Title IV—Section 404

The provisions of the contracts to be made are fully set forth in the bill, and there has been no change in the basic compensation except that the special compensation commences at 12 knots instead of 13 knots as in the original bill.

Title IV—Section 405

All definitions in this section have been carefully worked out so as to cover the contingencies that arise in a business of varied character.

Title IV—Section 406

The compensation limitation as to size of power-driven vessels remains the same, 1,500 tons, but compensation is paid to sailing vessels of over 1,000 tons.

Rating must be made by the American Bureau of Shipping, and a new paragraph has been added requiring one-half of the crew in both deck and engine department to be citizens of the United States.

Vessels built in a foreign country before the passage of this act and essential to the development of an American merchant marine can be transferred to American registry upon agreement by five members of the board, and receive compensation. This privilege is limited to three years from the passage of the act and is intended to admit only those vessels necessary to round out the merchant fleet, and in cases which require expeditious action.

Title IV—Sections 407 and 408

Foreign trade is particularly defined in these sections of the new bill.

Title IV—Section 409

It is required that after three years 75 percent of any owner's tonnage must be American owned and registered under the laws of the United States. This covers affiliated concerns and such concerns are closely described.

Title IV—Section 410

The board has the power upon vote of five members to increase or decrease the compensation when it is found advisable by the circumstances of the case.

Title IV—Section 412

Any vessel which has received compensation may be requisitioned in time of war or national emergency, the vessel so requisitioned or chartered shall receive a fair value for the purchase or service with no enhancement in value by the causes necessitating the taking, the owner shall under no circumstances receive consequential damages arising out of such taking or use.

Title IV—Section 413

Repairs, unless necessary for the safety of the vessel, shall be made in the United States or its territories including the Canal Zone, the exception in this section applies to feeder vessels, which do not travel between United States ports.

Title IV—Section 414

The carriage of the first, second and third class mails is provided for, the Post Office Department still making the contract directly with the vessels for the carriage of the parcels post. No change is made in the regulations, everything is carried on by the Post Office Department as at present excepting that the compensation for its carriage is paid into the merchant marine fund when the carriage is done by vessels receiving compensation from that fund.

Title IV—Sections 415 and 416

When a vessel receiving compensation is sold, its contract for the same is closed unless a new contract is made by the purchaser, with the exception that the purchaser must purchase the vessel subject to the right of the United States to take or use such vessel in emergency for the full term of the contract.

Title IV—Sections 417 to 419 Inclusive

The limitation of compensation is entered into fully in the new bill, and every endeavor has been made to protect the government from the many complications which arise from the many and various business situations that arise from the ramifications to be found in the shipping business.

Titles V and VII

The use of the Army and Navy transports necessary to build up the overseas shipping is continued in this bill as in the original bill, as is also the requirement that government officials use American ships whenever possible.

Title VI—Sections 601 to 603 Inclusive

It is endeavored in the bill to bring about an understanding between the Interstate Commerce Commission and the United States Shipping Board by arranging for a joint committee to clarify the situation in regard to through freight, so that something approaching the correlation between rail and water carriers in foreign countries can be covered in this country by our connecting rail and water lines.

Title VI—Section 604

The bill also clarifies the interstate commerce act by describing under what conditions a railroad can become interested in vessels.

Title VI—Section 605

It also arranges to enlarge the powers given the board by the Shipping Act of 1916 in Section 15 so that a thorough record of agreements between shipping companies, or between shipping companies and other carriers, shall be subject to the approval of the board; this covers all common carriers by water and includes the coastwise business. This section is subject to a heavy penalty for violation.

Title VI—Section 607

In order to make Section 28 of the Merchant Marine Act of 1920 operative, the bill has clarified the section, and it is believed that all delay in placing this section in operation should now be eliminated; as this gives preferential railroad rates to American vessels it will go a long way in assisting in securing the necessary cargo both of imports and exports for our ships.

It is provided in the amendment to Section 28 that the Shipping Board and the Interstate Commerce Commission have the power jointly to suspend the application of the provisions of this section when in their judgment it would operate to the prejudice of any particular port

Complete Text of Revised Merchant Marine Act, 1922

A BILL—To amend and supplement the Merchant Marine Act, 1920, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

TITLE I—AMENDMENTS TO THE MERCHANT MARINE ACT, 1920

SEC. 1. Section 5 of the Merchant Marine Act, 1920, is amended to read as follows:

"SEC. 5. (a) That in order to accomplish the declared purposes of this Act, and to carry out the policy declared in section 1 hereof, the board is authorized and directed to sell, as soon as practicable, consistent with good business methods and the objects and purposes to be attained by this Act, at public or private competitive sale after appraisement and due advertisement, to persons who are citizens of the United States, except as provided in section 6 of this Act, all the vessels referred to in section 4 of this Act or otherwise acquired by the board.

"(b) Any vessel may be sold without such advertisement or such competitive sale, if such action is specifically authorized by the board upon an affirmative vote of not less than five of its members, and if such vote and a full statement of the reasons for authorizing such sale are spread upon the minutes of the board.

"(c) Any sale under this section shall be made at such prices and on such terms and conditions, including the use or disposition of the vessel by the purchaser, as the board may prescribe; except that (1) the completion of the payment of the purchase price and interest shall not be deferred more than 15 years after the making of the contract of sale, (2) interest on the unpaid purchase price shall be payable at least annually at a rate of not less than 4 per centum per annum, and (3) the payments of principal shall be so arranged that the amounts due or paid under the contract of sale as principal up to any moment of time shall be sufficient to cover depreciation of the vessel up to such moment, unless the board waives this requirement upon the giving of adequate security.

"(d) All sales made under the authority of this Act shall be subject to the limitations and restrictions of section 9 of the Shipping Act, 1916, as amended."

SEC. 2. (a) Section 7 of the Merchant Marine Act, 1920, is amended by inserting after the first proviso thereof the following: "*Provided further,* That domestic communities primarily interested in such lines shall be understood to mean the geographical divisions of the coast lines of the United States known as the North Atlantic, South Atlantic, Gulf, and Pacific coasts, together with the particular ports from which such lines may run or be intended to run, and the territorial regions and zones naturally tributary to such ports and coastal divisions: *Provided further,* That the board shall not for the period of two years after the enactment of the Merchant Marine Act, 1922, sell such vessels to persons other than those who have the support, financial and otherwise, of the domestic communities primarily interested in such lines:"

(b) Such section is further amended by adding at the end thereof a new paragraph to read as follows:

"It is hereby declared to be the policy of Congress to discourage monopoly in the American merchant marine, and, in pursuance of this policy, the board is directed, in the development of its sales policy, to continue as far as possible and practicable, subject to the provisions of this section, all existing steamship routes and regular services, and to endeavor in every way to bring about the permanent establishment of such routes and services, and their retention, as far as possible, in the hands of persons having the support, financial and otherwise, of the domestic communities primarily interested in such routes and services. In carrying out the provisions of this section the board is directed to investigate fully all matters in connection therewith, and to conduct hearings at which the persons interested in such communities may have the opportunity to express their views as to the course to be pursued by the board and the methods to be adopted in carrying out the policy herein prescribed."

SEC. 3. Section 11 of the Merchant Marine Act, 1920, is amended to read as follows:

"SEC. 11. (a) That there is hereby established in the Treasury a revolving fund to be known as the 'United States Shipping Board Construction Loan Fund' (hereinafter in this section called the 'loan fund'). There shall be covered into the loan fund all moneys which at the time of the enactment of the Merchant Marine Act, 1922, are in the fund created by this section as in force before its amendment by such Act; and the board may set aside and cover into the loan fund all receipts of the board, except appropriations made by law and profits of the board from the operation of vessels; but the total amount of moneys covered into the loan fund (other than payments upon the principal and interest upon loans made therefrom) shall not exceed $125,000,000.

"(b) The board may use the loan fund, to such extent as it deems necessary, for making loans to aid persons, citizens of the United States, (1) in the construction by them in private shipyards of the United States of vessels of the best and most efficient type equipped with the most efficient and the most economical machinery and commercial appliances, or (2) in the equipping by them of vessels already built with such machinery and commercial appliances.

"(c) No loan shall be made for a longer time than 15 years. All loans shall bear interest, payable at least annually, upon the unpaid principal at a rate not less than 2 per centum per annum. No loan shall be made (1) in the case of a loan for construction purposes, for a greater sum than two-thirds of the cost of the vessel to be constructed, nor (2) in the case of a loan for equipment purposes, for a greater sum than two-thirds of the cost of the equipment or two-thirds of the value of the vessel when thus reequipped, whichever is the lesser. The board shall require such security for the loan, including a first lien upon the entire interest in the vessel with reference to which the loan is made, as it deems necessary in order to insure the repayment of the loan with interest. In case of a loan under this section made after the enactment of the Merchant Marine Act, 1922, all payments upon the principal and interest of the loan shall be covered into the loan fund."

TITLE II—TAXATION

INCOME TAX OF VESSEL OWNERS

SEC. 201. Title II of the Revenue Act of 1921 is amended by adding at the end thereof seven new sections to read as follows:

"EXEMPTIONS TO VESSEL OWNERS

"SEC. 265. (a) That the owner of a vessel of 1,500 gross tons or more (as shown on her certificate of admeasurement), registered, or enrolled and licensed, under the laws of the United States, shall, for the taxable year 1921 and for each of the eight taxable years following, be allowed as a deduction in computing net income, in addition to the deductions allowed by sections 214, 234, and 266, an amount which bears the same ratio to his net income during the taxable year attributable to the operations of such vessel (computed without the benefit of this section) as his gross income attributable to the foreign operations of such vessel bears to his entire gross income attributable to the operations of such vessel: *Provided,* That in no case shall the amount by which the taxes imposed by this Act are diminished by reason of such deduction, exceed 50 per centum of the amount certified under clause (1) of subdivision (b) of this section, plus 100 per centum of the amount certified under clause (2) of subdivision (b) of this section.

"(b) Such deduction shall not be allowed unless the United States Shipping Board (hereinafter in this title referred to as the 'Board') has certified to the Commissioner (1) the amount invested by the taxpayer, after the begining of the taxable year for which the deduction is claimed and prior to the time fixed by law for filing the return, in the building in private shipyards in the United States of new vessels of a type and kind approved by the Board, to be registered, or enrolled and licensed, under the laws of the United States, and (2) the amount set aside by the taxpayer after the beginning of the taxable year for which the deduction is claimed and prior to the time fixed by law for filing the return, in a trust fund for investment in the building in private shipyards in the United States of new vessels of a type and kind approved by the Board, to be registered, or enrolled and licensed, under the laws of the United States.

"(c) As soon as practicable after the filing of the return for the taxable year for which the deduction is claimed, the amount by which the taxes imposed by this Act are diminished by reason of the deduction allowed under subdivision (a) of this section shall be determined by the Commissioner with the approval of the Secretary and certified by the latter to the Board. The Commissioner shall notify the taxpayer, who may immediately withdraw from such trust fund the amount, if any, by which the amount set aside in such trust fund exceeds the amount which should have been so set aside, together with the ratable part of the interest on or earnings from such trust fund since the date of its establishment.

"(d) For the purposes of this section there shall be deemed attributable to the foreign operations of a vessel so much of the gross income attributable to the operations of such vessel as is attributable to the carriage of passengers, cargo, and mails taken on board at a port not in the coastwise trade and discharged at a port whether or not in the coastwise trade, or taken on board at a port whether or not in the coastwise trade and discharged at a port not in the coastwise trade.

"(e) In no case shall the amount by which the tax due from a taxpayer, other than a corporation, is diminished by reason of the deduction allowed by this section, exceed the amount by which the tax would have been diminished if such taxpayer were a corporation.

"(f) That portion of the amount of invested capital attributable to the vessel, which bears the same ratio to such invested capital as the amount allowed as a deduction under the provisions of this section bears to the amount of the entire net income for the taxable year attributable to the operations of such vessel (computed without the benefit of this section), shall be regarded as an inadmissible asset in computing the tax imposed by Title III of this Act.

"SEC. 266. (a) That in the case of the sale, during the taxable year 1921 or any of the eight taxable years following, of a vessel launched prior to January 1, 1914, which was at the time of the enactment of the Merchant Marine Act, 1922, registered, enrolled, or licensed, under the laws of the United States, and which at no time thereafter, up to the time of sale, was under a foreign registry or flag (or, in case of sale made prior to the enactment of such Act, was at the time of the sale registered, enrolled, or licensed, under the laws of the United States), the taxable gain derived from the sale shall be allowed as a deduction (in addition to the deductions allowed by sections 214, 234, and 265) in computing the net income of the owner, if he is a citizen of the United States within the meaning of the Shipping Act, 1916, as amended by the Merchant Marine Act, 1920. Except as provided in subdivision (b) this deduction shall not be allowed unless (after the beginning of the taxable year for which the deduction is claimed and prior to the time fixed by law for filing the return) the entire proceeds of the sale have been invested by the taxpayer, or set aside by him in a trust fund for investment, in the building in private shipyards in the United States of new vessels of a type and kind approved by the board, to be registered, or enrolled and licensed, under the laws of the United States.

"(b) If a part only of the proceeds of the sale has been so invested or set aside in a trust fund, the amount of the deduction allowed under subdivision (a) shall be an amount which bears the same ratio to the taxable gain derived from the sale as the part of the proceeds so invested or set aside in a trust fund bears to the entire proceeds of the sale.

"(c) Upon the completion of the new vessel or vessels they shall, for the purposes of sections 202, 214 and 234, be treated as taking the place of a like proportion of the vessel sold.

"(d) Where a vessel is exchanged for property, or for money and property, the transaction shall, for the purposes of this section, be deemed to be a sale with reference to (1) the money received in the exchange, and (2) that part of the property received in the exchange which, under the provisions of subdivisions (c) and (e) of section 202, is considered in determining the taxable gain from the exchange.

"SEC. 267. (a) That if a taxpayer establishes a trust fund for investment under the provisions of section 265 or 266, the amount so set aside under section 266, or an amount equal to 200 per centum of the amount set aside under section 265, as the case may be, shall be actually invested by the taxpayer, within a reasonable time to be determined by the Board, in the building in private shipyards in the United States of new vessels of a type and kind approved by the Board, to be registered, or enrolled and licensed, under the laws of the United States. Upon failure to invest all or any part of such amount within the reasonable time fixed by the Board, or upon failure to register, or enroll and license, the new vessel or vessels under the laws of the United States within a reasonable time fixed by the Board, the Board shall immediately notify the Commissioner, and (1) the amount which should have been invested under the provisions of section 266 and this section, which is not so invested, or the amount invested in a vessel or vessels not registered, or enrolled and licensed, under the laws of the United States, shall be deemed, for the purposes of section 266, to have never been set aside in a trust fund for investment, and (2) 50 per centum of the amount which should have been invested under the provisions of section 265 and this section, which is not so invested, or 50 per centum of the amount invested in a vessel or vessels not registered, or enrolled and licensed, under the laws of the United States, shall be deemed, for the purposes of section 265, to have never been set aside in a trust fund for investment. Any additional tax due by reason of this adjustment of the amount set aside in the trust fund for investment under sections 265 and 266, together with interest thereon at the rate of one-half of 1 per centum per month from the time the tax was due, shall be payable upon demand at any time, notwithstanding the provisions of section 250. The amount in

the trust fund shall be first applied in payment of such additional tax due, and the instrument creating the trust fund shall provide for such application.

"(b) Whenever the taxpayer establishes a trust fund for investment under the provisions of section 265 or 266, the interest on or earnings from the amount set aside in such fund shall belong to the fund, and, for the purposes of subdivision (a) of this section, shall be considered as being a part of the amount set aside in the fund.

"Sec. 268. That the Commissioner may require a taxpayer, who claims the benefit of the deduction allowed by section 265 or 266 and establishes a trust fund for investment, to furnish a bond with such security or surety as the Commissioner shall require, for an amount not less than the estimated income, war-profits and excess-profits taxes that would have been payable but for the deduction claimed under those sections. Such bond shall be conditioned upon (a) the investment of the fund in accordance with the provisions of section 267, or the payment of the tax, together with interest, due by reason of failure to so invest, and (b) the registering, or enrolling and licensing, of the new vessels under the laws of the United States within the time fixed by the Board.

"Sec. 269. (a) That the amount invested under the provisions of sections 265, 266, or 267, or set aside in a trust fund for investment under the provisions of sections 265 or 266, must be from funds other than any loan which the taxpayer may have received from the Board under the provisions of section 11 of the Merchant Marine Act, 1920, as amended by the Merchant Marine Act, 1922.

"(b) So much of sections 265 and 266 as requires that the investment, or the setting aside of an amount in a trust fund for investment, shall be made prior to the time fixed by law for filing the return for the taxable year for which the deduction is claimed, shall be deemed complied with by a taxpayer with respect to the deduction for a taxable year ending prior to the time of the enactment of the Merchant Marine Act, 1922, if he makes such investment, or sets aside such amount in a trust fund, within 75 days after the enactment of such Act.

"Sec. 270. That section 265 and section 266 shall be deemed to have been in force on January 1, 1921.

"Sec. 271. That the benefits of section 265 and section 266 shall be allowed to the members of a partnership and the beneficiaries of an estate or trust under regulations prescribed by the Commissioner, with the approval of the Secretary."

Sec. 202. (a) Subdivision (a) of section 212 of the Revenue Act of 1921 is amended by striking out the word and figures "section 214" and inserting in lieu thereof the following: "sections 214, 265, and 266."

(b) Section 232 of the Revenue Act of 1921 is amended by striking out the word and figures "section 234" and inserting in lieu thereof the following: "sections 234, 265, and 266."

Depreciation of Vessels

Sec. 203. Title II of the Revenue Act of 1921 is further amended by adding at the end thereof, after the sections added thereto by section 201 of this Act, a new section to read as follows:

"Depreciation of Vessels

"Sec. 272. (a) That in the case of vessels registered, enrolled, or licensed, under the laws of the United States, the reasonable allowance for exhaustion, wear and tear, and obsolescence, provided in paragraph (8) of subdivision (a) of section 214, and in paragraph (7) of subdivision (a) of section 234, shall be determined, and allocated to the years in which sustained, under rules and regulations prescribed by the United States Shipping Board.

"(b) In the case of a vessel of 1,000 gross tons or more (as shown by her certificate of admeasurement), registered, enrolled, or licensed, under the laws of the United States, acquired after August 1, 1914, and prior to January 1, 1921, there shall be allowed for the taxable year 1922 and each of the four succeeding taxable years, a reasonable deduction for the exceptional decrease in value thereof since the date of acquisition, but not again including any amount otherwise allowed under this Act or any previous Act of Congress as a deduction in computing net income. This deduction shall be determined and allocated to the taxable year 1922 and the four succeeding taxable years under rules and regulations prescribed by the United States Shipping Board. At any time before March 15, 1927, the Commissioner may, and at the request of the taxpayer shall, reexamine the return, and if he then finds as a result of an appraisal or from other evidence that the value on which the tentative deduction for exceptional decrease in value was based, was incorrect or has changed, the income, war-profits and excess-profits taxes for the year or years affected shall be redetermined; and the amount of tax due upon such redetermination, if any, shall be paid upon notice and demand by the collector, and the amount of tax overpaid, if any, shall be credited or refunded to the taxpayer in accordance with the provisions of section 252.

"(c) This section shall take effect as of January 1, 1922."

Income Tax Credit For Transportation By Water

Sec. 204. Title II of the Revenue Act of 1921 is further amended by adding, after the section added thereto by section 203 of this Act, a new section to read as follows:

"Credit For Amounts Paid For Water Transportation

"Sec. 273. (a) That the tax computed under this title (less the credits provided by sections 222 and 238) shall be credited with an amount equal to 5 per centum of the amount of freight money paid (not accrued), by the taxpayer and for his own account, during the taxable year and after the enactment of the Merchant Marine Act, 1922, for the transportation after the enactment of such Act in a vessel, registered, or enrolled and licensed, under the laws of the United States, of cargo not taken on board at a port in the coastwise trade and discharged at another port in such trade. If such transportation is in a vessel chartered by the owner of any part of the cargo from a person not affiliated with such owner within the meaning of subdivision (b), the amount of freight money paid by the charterer for the transportation of such part of the cargo shall, for the purposes of this section, be such amount as is determined by the United States Shipping Board and certified by it to the Commissioner. In such cases the credit shall not be originally claimed by the taxpayer in his return, unless the return is accompanied by a copy of the certificate of the Shipping Board.

"(b) The credit provided in this section shall not be allowed with reference to transactions between persons who are affiliated. For the purposes of this section two or more corporations or associations shall be held to be affiliated if one corporation or association owns directly, or controls through closely affiliated interests or by a nominee or nominees, more than 50 per centum of the outstanding stock of or interest in the other; or if more than 50 per centum of the outstanding stock of or interest in such corporations or associations is owned directly, or controlled through closely affiliated interests or by a nominee or nominees, by the same interests. For the purposes of this section an individual or partnership shall be held to be affiliated with a corporation or association if more than 50 per centum of the outstanding stock of or interest in the corporation or association is owned directly, or controlled through closely affiliated interests or by a nominee or nominees, by the individual or partnership."

Government Compensation to Vessels as Income

Sec. 205. Subdivision (b) of section 213 of the Revenue Act of 1921 is amended by striking out the period at the end of paragraph (13) thereof, and inserting in lieu thereof a semicolon, and by adding after paragraph (13) a new paragraph to read as follows:

"(14) Amounts received by the owner of a vessel under section 403 of the Merchant Marine Act, 1922, out of the merchant marine fund created by such Act."

Tonnage Duties

Sec. 206. After 30 days from the enactment of this Act all amounts required to be levied, collected, and paid as tonnage duties, tonnage taxes, or light money, except such amounts as are required to be paid into the Treasury of the Philippine Islands, shall be double the amounts which would be required to be levied, collected, and paid if this Act had not been enacted. This section shall not apply in the case of a sailing vessel (as defined in section 405) of less than 1,000 gross tons, or in the case of any other kind of vessel of less than 1,500 gross tons.

TITLE III—TRANSPORTATION OF IMMIGRANTS BY WATER

Sec. 301. As nearly as practicable one-half of the total number of immigrants, admitted to the United States in any fiscal year, shall be transported in vessels registered, or enrolled and licensed, under the laws of the United States.

Sec. 302. The Commissioner General of Immigration with the approval of the Secretary of Labor shall make regulations necessary for the enforcement of section 301. All such regulations, in so far as they relate to the administration of such section by diplomatic or consular officers of the United States, shall be subject to the approval of the Secretary of State.

Sec. 303. Section 301 shall not take effect as to immigrants transported in a vessel documented under the laws of any foreign country until a time fixed by proclamation of the President. The President is authorized and directed, whenever in his opinion the provisions of this title or of regulations made thereunder, are or may be in conflict with treaties or conventions with a foreign country, to take such steps as may, in his opinion, be necessary to remove such conflict. Whenever, in his opinion, no such conflict exists in the case of any country he shall so proclaim, and the provisions of this title and regulations made thereunder shall take effect in the case of immigrants transported in vessels documented under the laws of such country at the time specified in his proclamation therefor.

Sec. 304. The term "United States" as used in this title in a geographical sense means the several States, the Territories of Alaska and Hawaii, the District of Columbia, Porto Rico, and the Virgin Islands.

TITLE IV—COMPENSATION TO VESSELS OF THE UNITED STATES

Definitions

Sec. 401. When used hereinafter in this Act—

(a) The term "person" means individual, partnership, corporation, or association;

(b) The term "United States," when used in a geographical sense, means the several States and the District of Columbia;

(c) The term "citizen of the United States" has the meaning assigned to it by section 2 of the Shipping Act, 1916, as amended by the Merchant Marine Act, 1920; and

(d) The term "board" means the United States Shipping Board.

Merchant Marine Fund

Sec. 402. There is hereby established in the Treasury a fund to be known as the "Merchant Marine Fund" (hereinafter in this title called the "fund"). The Secretary of the Treasury is authorized and directed to set aside in or credit to such fund, upon receipt, the following sums paid into the Treasury after the enactment of this Act:

(a) All tonnage duties, tonnage taxes, or light money, paid under law in force at the time of the enactment of this Act and under section 206 of this Act;

(b) 10 per centum of the amount of all customs duties paid under law in force at the time of the enactment of this Act or subsequently enacted;

(c) The amount which, except for the fact that the owner of the vessel has in force a contract with the board for compensation in respect to such vessel in accordance with the provisions of this title, would be payable, under law or any contract actually made thereunder, for the transportation of mails of any kind, except parcel post, by such vessel. Such amount shall be certified to the Secretary of the Treasury by the Postmaster General at least monthly; and

(d) All excess earnings paid by the owner of any vessel under the provisions of section 417.

Contract For Compensation

Sec. 403. (a) In order to aid the development and maintenance of the American Merchant Marine, to promote the growth of the foreign commerce of the United States, to contribute to the national defense and to carry out the policy set forth in section 1 of the Merchant Marine Act, 1920, the board is authorized and directed on behalf of the United States to enter into a contract with any person, a citizen of the United States who is the owner of a vessel, for the payment of compensation in respect to such vessel, subject to the limitations of this title. The board shall not be required to enter into such contract unless in the judgment of the board such person possesses such ability, experience, resources and character as, in the opinion of the board, to justify a belief that the payment of the compensation will be reasonably calculated to carry out such policies and otherwise promote the general welfare of the United States. The board shall not refuse to enter into any such contract on the ground that such person is not so qualified unless such refusal is specifically authorized by an affirmative vote of not less than five members of the board, and unless the vote and a full statement of the reasons for the refusal are spread upon the minutes of the board.

(b) Such contract shall provide that it shall be made for a period not exceeding ten years from the date thereof, and shall provide that the payments of the compensation shall be made at reasonable intervals not exceeding six months.

(c) The Secretary of the Treasury is authorized and directed to pay, out of any moneys in the fund, compensation to the owner of any vessel with whom there has been made a contract under this section; but such payment shall be made only upon vouchers signed by the chairman of the board, under authorization of the board. All moneys in the fund are hereby permanently appropriated for the purpose of making such payments and the refunds authorized by subdivision (j) of section 417.

Amount of Compensation

Sec. 404. Compensation shall be computed as follows: For each gross ton of the vessel for each 100 nautical miles covered by the vessel, there shall be paid—

(a) Regardless of the speed of which the vessel is capable,—one-half of one cent; and

(b) In case of a power-driven vessel capable of making (when self-propelled solely by machinery) a speed of 12 knots or over when on such draft as the owner may select, and in addition to any amount payable to such vessel under subdivision (a),—

(1) One-tenth of one cent,—if such speed is 12 knots or over but less than 13 knots;

(2) Two-tenths of one cent,—if such speed is 13 knots or over but less than 14 knots;

(3) Three-tenths of one cent,—if such speed is 14 knots or over but less than 15 knots;

(4) Four-tenths of one cent,—if such speed is 15 knots or over but less than 16 knots;

(5) Five-tenths of one cent,—if such speed is 16 knots or over but less than 17 knots;

(6) Seven-tenths of one cent,—if such speed is 17 knots or over but less than 18 knots;

(7) Nine-tenths of one cent,—if such speed is 18 knots or over but less than 19 knots;

(8) One and one-tenth cents,—if such speed is 19 knots or over but less than 20 knots;

(9) One and three-tenths cents,—if such speed is 20 knots or over but less than 21 knots;

(10) One and five-tenths cents,—if such speed is 21 knots or over but less than 22 knots;

(11) One and eight-tenths cents,—if such speed is 22 knots or over but less than 23 knots; and

(12) Two and one-tenth cents,—if such speed is 23 knots or over.

SEC. 405. For the purpose of computing compensation under this title—

(a) A vessel shall be held to be power-driven if it is equipped so as to be self-propelled through the use of machinery, and if the rated horsepower of the propulsive machinery exceeds one-third the gross tonnage of the vessel;

(b) A vessel shall be held to be a sailing vessel if it is equipped so as to be self-propelled through the use of sails, and is not equipped so as to be self-propelled through the use of machinery;

(c) The gross tonnage of a vessel shall be as determined under the laws of the United States and stated upon the vessel's certificate of admeasurement;

(d) The speed which a vessel is capable of making on such draft as the owner may select, shall be ascertained by the board at such reasonable intervals and by such methods as the board may by regulation prescribe;

(e) The mileage covered by the vessel shall be determined solely by the distances of the direct, customary route, for vessels of the same type and kind upon similar voyages, between the ports touched by the vessel, based upon tables of such distances approved by the board; except that if such distances do not, in the opinion of the board, fairly represent the distances which, under efficient operation, are required actually to be traversed by the vessel upon its voyage, the board may increase the mileage to such an extent as it deems fair and reasonable; but in no case shall the mileage as so increased be in excess of the mileage actually traversed by the vessel;

(e) In computing mileage a fractional part of 100 miles shall be disregarded unless in excess of 50 miles, in which case it shall be counted as 100 miles;

(f) Any power-driven vessel of 5,000 gross tons or less but of 1,500 gross tons or over, shall be considered as if it were a vessel of 5,000 gross tons.

When Vessels Not Entitled to Compensation

SEC. 406. (a) Compensation shall not be paid in respect to any sailing vessel whose tonnage is less than 1,000 gross tons, and shall not be paid in respect to any other kind of vessel whose tonnage is less than 1,500 gross tons.

(b) Compensation shall be paid in respect to any vessel only for mileage covered while the vessel—

(1) Is a privately owned merchant vessel; and

(2) Is registered, or enrolled and licensed, under the laws of the United States; and

(3) Is self-propelled by sails or machinery except when in distress or being aided by means of tugs or other assistance on entering or leaving port or in navigating any inland or restricted waterway; and

(4) Is classed by the American Bureau of Shipping in the highest classification open to vessels of its type and kind according to the rules of the bureau; and

(5) Carries a crew (exclusive of licensed officers required by law) at least two-thirds of which are citizens of the United States, and the remainder of which are individuals eligible to United States citizenship. During the first year after the enactment of this Act the required number of citizens of the United States shall be one-half instead of two-thirds; and, during the second year, six-tenths instead of two-thirds. In the case of passenger vessels the provisions of this paragraph shall apply only to the deck and engine departments. If the vessel is deprived of the services of any member of the crew by desertion, casualty, or other cause beyond the control of the master, in any port outside the United States or on the high seas, the right of the vessel's owner to compensation, during the period prior to the next arrival of the vessel at a port in the United States, shall not be impaired by failure to comply with the provisions of this paragraph, provided the owner and the master of the vessel exercise reasonable diligence to procure the necessary individuals to comply with such provisions. If the vessel is outside the United States at the time of the enactment of this Act, or on the first day of the second or third year after the enactment of this Act, the owner shall not be required to comply with the provisions of this paragraph applicable to such year until her first arrival at a port in the United States, if he complies with the provisions of this paragraph applicable to the previous year.

(c) Compensation shall not be paid in respect to any vessel unless the vessel—

(1) Is registered, enrolled, or licensed, under the laws of the United States on the sixtieth day after the enactment of this Act; or

(2) Is built in the United States, its Territories or possessions, or the Canal Zone, after the enactment of this Act; or

(3) Is, at the time of the enactment of this Act, undocumented and owned by a person, a citizen of the United States, and is not thereafter documented under the laws of any foreign country; or

(4) Is owned by the United States at the time of the enactment of this Act and is not thereafter documented under the laws of any foreign country, or

(5) Was built in a foreign country before the enactment of this Act, and is, within three years after the enactment of this Act, registered under the laws of the United States; except that compensation shall be paid in respect to any such foreign-built vessel only if such vessel is, upon the affirmative vote of at least five of the members of the board, specifically authorized to receive compensation and specifically certified to be essential to the proper development of the merchant marine of the United States by reason of the particular type or kind of vessel, and if such vote and a full statement of the reasons for such authorization and certification are spread upon the minutes of the board.

Foreign Trade

SEC. 407. (a) Except as provided in subdivision (b), (d), or (e), a vessel shall for the purposes of this title, be held to be engaging in foreign trade while operated on any voyage as a merchant vessel.

(b) A vessel shall not, for the purpose of this title, be held to be engaged in foreign trade while carrying any passengers or cargo—

(1) Which are taken on board at a port in the United States and discharged at a port in the United States;

(2) Which are taken on board at a port in the United States and discharged at a port in Alaska or Porto Rico;

(3) Which are taken on board at a port in Alaska or Porto Rico and discharged at a port in the United States;

(4) Which are taken on board at a port in the United States and discharged at a port in Hawaii, if the revenue accruing to the vessel by reason of the carriage of such passengers and cargo amounts to more than one-fourth the total revenue accruing to the vessel by reason of the carriage from point of origin to point of distination of passengers and cargo on board at the time of departure from the last port of call in the United States;

(5) Which are taken on board at a port in Hawaii and discharged at a port in the United States, if the revenue accruing to the vessel by reason of the carriage of such passengers and cargo amounts to more than one-fourth the total revenue accruing to the vessel by reason of the carriage from point of origin to point of distination of the passengers and cargo on board at the time of departure from the last port of call in Hawaii; or

(6) Which are taken on board at a port in Alaska, Hawaii, Porto Rico, the Virgin Islands, the Philippine Islands, or the Canal Zone, and discharged at a port in the same Territory, possession, or Zone.

(c) Subdivision (b) shall not apply (1) to a voyage for the carriage of passengers on a special or sight-seeing tour, or for scientific purposes, if the vessel does not in the judgment of the board carry passengers or cargo in competition with vessels in the coastwise trade; nor (2) to merchant vessels while operating as auxiliaries to the military or naval forces of the United States.

(d) A vessel shall not, for the purposes of this title, be held to be engaged in foreign trade while moving without passengers or cargo—

(1) Between ports in the United States, unless the next carriage of passengers or cargo is to or from a port outside the United States, Alaska, Hawaii, and Porto Rico;

(2) Between the United States and Alaska, Hawaii, or Porto Rico, unless the next carriage of passengers or cargo is to or from a port outside the United States and outside such Territory or possession:

(3) Between a port in Alaska, Hawaii, or Porto Rico and a port in the same Territory or possession, unless the next carriage of passengers or cargo is to or from a port outside such Territory or possession and outside the United States; or

(4) Between a port in the Virgin Islands, the Philippine Islands, or the Canal Zone, and a port in the same possession or Zone, unless the next carriage of passengers or cargo is to or from a port outside such possession or Zone.

(e) A vessel shall not, for the purpose of this title, be held to be engaged in foreign trade while operating on the Great Lakes or adjacent or connecting waterways, unless the voyage begins or ends east of Quebec, Canada.

SEC. 408. (a) Compensation shall be paid in respect to any vessel only for mileage covered while the vessel is engaged in foreign trade upon a voyage of which one of the ports is a port of the United States, its Territories or possessions, or the Canal Zone; except that any vessel engaged in foreign trade shall be paid compensation for mileage covered in such trade during any period of time (1) if the vessel has entered or cleared from a port of the United States at any time during the 12 months prior to such period of time and after the making of the contract; or (2) if the vessel during the six months ending with such period of time has derived at least one-half of the total revenue accruing to it by reason of the carriage of passengers and cargo, from passengers and cargo received from or delivered to vessels which are registered, or enrolled and licensed, under the laws of the United States and whose voyage began or terminated at a port in the United States, its Territories or possessions, or the Canal Zone.

(b) Compensation shall not be paid in respect to any vessel for mileage covered upon a voyage in foreign trade during which the vessel enters or clears from a port in the United States, its Territories or possessions, or the Canal Zone, if the distance between the terminal ports of the voyage is less than 150 nautical miles.

Ownership of Vessels by Citizens of the United States

SEC. 409. (a) Compensation shall be paid in respect to any vessel only for mileage covered while the vessel is owned by a person, a citizen of the United States.

(b) Compensation earned after three years from the enactment of this Act shall not be paid to any vessel owner unless, at all times during the period over which such compensation was earned, at least 75 per centum of (1) the total gross tonnage of all vessels (other than those documented for the coastwise trade only and other than those operating on the Great Lakes or adjacent or connecting waterways upon voyages neither beginning nor terminating east of Quebec, Canada), which are owned or chartered by such vessel owner, or for which such owner acts as agent, plus (2) the total gross tonnage of all such vessels owned or chartered by any person affiliated with such vessel owner, or for which such affiliated person acts as agent, is comprised of vessels registered under the laws of the United States.

(c) For the purpose of subdivision (b)—

(1) Two or more corporations or associations shall be held to be affiliated if one corporation or association owns directly, or controls through closely affiliated interests or by a nominee or nominees, 50 per centum or more of the outstanding voting stock or voting power of the other, and owns directly, or through closely affiliated interests or by a nominee or nominees, 80 per centum or more of all the outstanding stock of or interest in the other; or if 50 per centum or more of the outstanding voting stock or voting power of two or more corporations or associations is owned directly, or controlled through closely affiliated interests, or by a nominee or nominees, by the same interests, and 80 per centum or more of all the outstanding stock of or interest in such corporations or associations is owned directly, or through closely affiliated interests or by a nominee or nominees, by the same interests;

(2) An individual or partnership shall be held to be affiliated with a corporation or association if 50 per centum or more of the outstanding voting stock or voting power of such corporation or association is owned directly, or controlled through closely affiliated interests or by a nominee or nominees, by the individual or partnership, and 80 per centum or more of all the outstanding stock of or interest in the corporation or association is owned directly, or through closely affiliated interests or by a nominee or nominees, by the individual or partnership.

(d) The board may suspend from time to time the provisions of subdivision (b) in respect to a power-driven vessel of a particular type or kind, which any person desires to own or charter, if, in the opinion of the board, vessels of such type or kind registered, or enrolled and licensed, under the laws of the United States are not reasonably available for the purposes desired. Any vessel in respect to which such suspension is made, shall not be counted in computing gross tonnage for the purposes of subdivision (b).

INCREASE AND DECREASE OF COMPENSATION

SEC. 410. (a) Whenever the board determines that in order to promote the welfare of the United States, the operation of vessels in any particular service, or of any particular type and kind, is desirable and necessary, and that the rate of compensation authorized under section 404 is insufficient to induce the operation of vessels in such service, or of such type and kind, the board in making the contract for compensation may provide therein for the increase of the rate of compensation authorized in respect to such vessel under said section, to such an extent as it deems necessary to procure the establishment and maintenance of such service and the operation of vessels in such service, or the operation of vessels of such type and kind; but the rate of compensation as so increased shall not exceed twice the rate authorized by said section. As used in this subdivision and in section 411 the term "service" includes the route on which the vessel operates, the frequency of sailings, and the speed which she maintains.

(b) Whenever the board determines that the rate of compensation authorized under section 404 is excessive under the special circumstances of any particular case, it shall, in making the contract for compensation, provide therein for the decrease of the rate of compensation to such an extent as it deems advisable.

(c) After the making of the contract of compensation the board may, with the consent of the other party thereto, decrease or, within the limit provided by subdivision (a), increase, the rate of compensation to be paid.

(d) No increase or decrease shall be made under the provisions of this section unless such increase or decrease is specifically authorized by the board upon the affirmative vote of not less than five members, and unless such vote and a full statement of the reasons for the increase or decrease are spread upon the minutes of the board.

MAINTENANCE OF SERVICE OR ROUTE

SEC. 411. (a) The contract for compensation in respect to any vessel may provide that the vessel shall be operated in a particular service (1) if the rate of compensation is based thereon, and (2) if the contract also provides a different rate of compensation to be paid in respect to any period of time after the obligation of the owner to operate the vessel in such service has been terminated as provided in subdivision (b).

(b) If the contract provides for the operation of the vessel in a particular service the obligation of the owner to so operate the vessel may be terminated upon six months' written notice to the board. Upon the failure of the owner to operate the vessel in such service (act of God and restraint of princes excepted) before his obligation has terminated, then, (1) all rights to compensation earned since the last time for payment provided in the contract may, at the option of the board, be forfeited, and (2) the board may terminate the entire contract.

REQUISITION OF COMPENSATED VESSELS

SEC. 412. Any vessel in respect to which a contract for compensation is made, may, at any time during the period for which the contract is made, be taken and purchased or used by the United States for national defense or during any national emergency declared by proclamation of the President. In such event the owner shall be paid the fair actual value of the vessel at the time of taking, or paid fair compensation for her use based upon such fair actual value; but in neither case shall such fair actual value be enhanced by the causes necessitating the taking. In the case of a vessel taken and used, but not purchased, the vessel shall be restored to the owner in a condition at least as good as when taken, less reasonable wear and tear, or the owner shall be paid an amount for reconditioning sufficient to place the vessel in such condition. The owner shall not be paid for any consequential damages arising from such taking and purchase or use. If there is a disagreement between the United States and the owner of the vessel as to the fair actual value, fair compensation, or amount for reconditioning, such value, compensation, or amount shall be determined by arbitration, one of the arbitrators to be selected by the President, one by the owner of the vessel, and the third by the two thus selected, or, if they can not agree, by the Chief Justice of the United States.

REPAIRS, RENEWALS, AND RECONDITIONING OF COMPENSATED VESSELS

SEC. 413. All repairs, renewals, or reconditioning of any vessel in respect to which a contract for compensation is made, or of the machinery or equipment of the vessel, shall be done in a port in the United States, its Territories or possessions, or the Canal Zone; except that repairs or renewals may be made in a foreign port, if the repairs or renewals are essential to the safety of the vessel, its passengers, crew, or cargo, or are made to a vessel operating exclusively between foreign ports and entitled to compensation solely by reason of the provisions of clause (2) of subdivision (a) of section 408. The board shall refuse to pay any person who fails to perform his obligations under this section, such amount of compensation as the board may determine.

CARRIAGE OF MAILS BY COMPENSATED VESSELS

SEC. 414. (a) A vessel in respect to which a contract for compensation is made, shall, whether or not such vessel is built in the United States, transport free for the whole or any part of any voyage which the vessel actually makes or is required under the contract to make, mail matter of any kind, except parcel post, in such amounts as the Postmaster General may require. Such transportation shall be subject to the provisions of law and regulations made thereunder (including the imposition by the Postmaster General of fines and penalties for delays and irregularities in the performance of service) pertaining to the conveyance of the mails.

(b) The rights of any person under law or any contract made thereunder, for compensation in respect to any vessel for the transportation by such vessel of mails of any kind, except parcel post, shall be terminated if such person has made a contract for compensation under this title in respect to such vessel. Nothing in this title shall be held to relieve such person from the performance of his obligations under such law or contract.

SALE OF COMPENSATED VESSELS

SEC. 415. If a vessel in respect to which a contract for compensation is made, is sold prior to the expiration of the contract, the compensation shall cease, unless a new contract therefor is made by the board with the purchaser.

SEC. 416. If a contract for compensation has been made with respect to a vessel, any person who purchases such vessel before the expiration of the term for which the contract was made shall be held to take the vessel with notice of, and subject to, the right of the United States to take and purchase or use such vessel as provided in section 412.

REPAYMENT OF COMPENSATION

SEC. 417. (a) When used in this section, the terms "taxable year," "gross income," "net income," and "invested capital" shall have the same meaning as when used in the Revenue Act of 1921.

(b) The owner of a vessel or vessels who has made a contract with the board for compensation in respect thereto shall pay to the United States 50 per centum of the amount by which his net income for the taxable year, attributable to the operations of such vessels, exceeds 10 per centum of his invested capital for such year attributable to such vessels; but in no case shall the amount so to be paid exceed the amount of compensation earned in respect to such vessels during the taxable year under a contract made under this title by the owner.

(c) In computing the gross income attributable to the operations of the vessels there shall be included the amount of compensation earned under this title in respect to the vessels during the taxable year. In computing the net income attributable to the operations of the vessels there shall be deducted from gross income a reasonable amount, determined by the board and certified by it to the Commissioner of Internal Revenue, as representing the fair value of the products, services, or facilities furnished by the owner of the vessels in connection with the operations of the vessels. There shall not be allowed as a deduction in computing the net income attributable to the operations of the vessels the deduction provided in section 265 of the Revenue Act of 1921 as amended by this Act.

(d) If the owner of the vessels uses them in whole or in part for the transportation of his own property, his gross income attributable to the operations of the vessels in transporting such property shall be considered to be such amount as is determined by the board, and certified by it to the Commissioner of Internal Revenue, as representing the fair value of the services performed by the vessels in transporting such property.

(e) If the owner of the vessels is an individual, a partnership, or an estate or trust, the invested capital shall be determined under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, so as to equal, as nearly as may be practicable, the invested capital that would be allowable to such owner if a corporation.

(f) For the purpose of making an accurate distribution or apportionment of profits, income, deductions, or invested capital, in computing net income and invested capital for the taxable year, among two or more trades or businesses (whether incorporated or unincorporated, or whether or not organized or created in the United States) controlled directly or indirectly by the same interests, the Commissioner of Internal Revenue may consolidate the accounts of such trades or businesses in any of the following cases:

(1) If the person conducting one of such trades or businesses in dealing with the person conducting another, bought from or sold to the other person during the taxable year products, services or facilities at prices above or below the current market price, thus effecting an artificial distribution of profits;

(2) If one such person in any way so arranged his financial relations with another such person during the taxable year as to assign to either a disproportionate share of net income or invested capital; or

(3) Where for any reason it appears to the Commissioner of Internal Revenue that the net income or invested capital attributable to the vessels as shown by the return of the owner does not fairly reflect the actual or true net income or invested capital of the owner.

(g) Every person liable for the payment provided for in subdivision (b) shall make, at the time and in the manner provided by law for making his income-tax return, a return, in such form as may be prescribed by the Commissioner of Internal Revenue, stating his net income attributable to the operations of the vessels, his invested capital attributable to the vessels, and any other information relating to the determination of the amount payable under this section, which may be required by the Commissioner. A copy of such return, together with all schedules and data submitted therewith, shall be transmitted to the board at the same time that the return is filed.

(h) The entire amount for which the owner of the vessels is liable under this section shall be due and payable at the same time and in the same manner, and shall be collected in the same manner, as the first installment of income tax imposed by law.

(i) For the purposes of this section the amount of compensation earned in respect to the vessels during the taxable year shall be determined by the board and certified by it to the Commissioner of Internal Revenue.

(j) Amounts paid under this section shall be covered into the Treasury to the credit of the Merchant Marine Fund created by section 402. Any refunds due on account of overpayment shall be paid out of such fund on vouchers approved by the Commissioner of Internal Revenue and countersigned by the chairman of the board.

(k) The provisions of Titles I, II, III, and XIII of the Revenue Act of 1921, including penal and other provisions relating to the assessment, collection, remission, or refunding of income and excess-profits taxes imposed by Act of Congress, and the provisions of any other internal-revenue law of the United States relating to the assessment, collection, remission, or refunding of such taxes, shall, so far as practicable, extend and be applicable to the determination, collection, remission, or refunding of the payments provided for in this section.

(l) The Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall make rules and regulations for the enforcement of the provisions of this section, and shall have charge of the administration of this section.

OBLIGATION OF VESSEL OWNER UNDER CONTRACT FOR COMPENSATION

SEC. 418. (a) The board shall provide in every contract for compensation with any person, that such person agrees to accept and comply with the provisions of sections 412, 413, 414, 415, and 417. Whether or not the contract does so provide, such person shall be held to have so agreed.

(b) Any contract for compensation with any person may be canceled by him at any time without the consent of the board; but the cancellation shall not relieve him of his obligations under sections 412 and 417, or of any obligation into which he may have entered, pursuant to the provisions of section 411, to operate the vessel in a particular service.

(c) The board shall provide in the contract no terms or conditions except those which are (1) specified in subdivision (a) or in section 411, or (2) necessary to carry out the provisions of sections 411, 412, 413, 414, 415, and 417, or (3) necessary to the ascertainment and determination of the amount of compensation, at the rate fixed in the contract, which under the provisions of this title is properly payable.

FINAL DETERMINATION OF AMOUNT OF COMPENSATION

SEC. 419. The determination of the board as to the amount of compensation to which any person is entitled under the provisions of this title, shall not be subject to review by the General Accounting Office.

TITLE V—ARMY AND NAVY TRANSPORTS

SEC. 501. Whenever in the judgment of the President adequate transportation facilities to meet any or all of the needs of the Army, Navy, or Marine Corps are afforded by vessels registered, or enrolled and licensed, under the laws of the United States, he may direct the discontinuance in whole or in part of the transport service of either the Army or the Navy and transfer to the board or place out of commission any of the vessels now or hereafter engaged in either of such services. Whenever such dis-

position is made the Secretary of War and the Secretary of the Navy respectively are authorized and directed to enter into contracts with owners of vessels registered, or enrolled and licensed, under the laws of the United States, for such transportation as may be required by the Army, the Navy, or the Marine Corps, respectively. Such contracts may be for a term of ten years. The board shall furnish whatever assistance may be necessary in the making of such contracts. There is hereby authorized to be appropriated such sums as are necessary to meet the payments required under such contracts.

TITLE VI—PROVISIONS RELATING TO RAIL AND WATER TRANSPORTATION

DEFINITIONS

SEC. 601. As used in this title the term "commission" means the Interstate Commerce Commission.

INTERRELATIONS OF RAIL AND WATER TRAFFIC

SEC. 602. (a) It is hereby declared to be the policy of Congress to promote, encourage, and develop water transportation, service, and facilities in connection with the commerce of the United States, and to foster and preserve in full vigor both rail and water transportation, and the board and the commission are hereby severally authorized, empowered, and directed to co-operate to that end.

(b) The board and the commission are authorized and directed to create a joint board, selected from among their members, officers, and employees, to study the conditions and interrelations of rail and water traffic, and the principles and methods essential to accomplishing the policy declared in subdivision (a).

(c) The joint board shall appoint a secretary who shall keep minutes of its meetings, which minutes shall be furnished to the members of the board and of the commission. The joint board shall hold regular semi-monthly and such additional meetings as may be necessary to transact properly its business.

(d) The joint board shall formulate and make such recommendations to the board and the commission, not inconsistent with law, pertaining to the interrelations of rail and water traffic, as it deems necessary to accomplish the policy declared in subdivision (a). The board shall make effective, by such means as are granted it by law, any such recommendation upon any matter within its jurisdiction, if such recommendation is approved by the board. The commission shall have a like duty as to any such recommendation upon any matter within its jurisdiction.

(e) None of the provisions of this section shall be construed to affect the power or jurisdiction of the commission, or to confer upon the board concurrent power or jurisdiction over any matter within the power or jurisdiction of the commission.

EXPORT BILLS OF LADING

SEC. 603. Paragraph (4) of section 25 of the Interstate Commerce Act, as amended, is amended by adding at the end thereof a new sentence to read as follows: "In making rules and regulations prescribing the form of such through bills of lading, the commission shall adopt as the portion thereof governing the carriage of goods by water in foreign commerce such form as may be certified to the commission by the United States Shipping Board for such purpose."

RAIL-OWNED WATER LINES

SEC. 604. Paragraph (9) of section 5 of the Interstate Commerce Act, as amended, is amended by striking out the period at the end thereof and inserting in lieu thereof a colon and the following: "*Provided,* That the foregoing provisions of this paragraph shall not apply in any case where such common carrier by water or such vessel is engaged exclusively (a) in trade (other than with foreign contiguous territory) not included in the coastwise trade, or (b) in trade between ports in the United States and ports in the Philippine Islands."

AGREEMENTS BETWEEN CARRIERS AFFECTING WATER TRANSPORTATION

SEC. 605. Section 15 of the Shipping Act, 1916, is amended to read as follows:

"SEC. 15. (a) That every common carrier by water, or other person subject to this Act, shall file immediately with the board a true copy, or, if oral, a true and complete memorandum, of every agreement with another such carrier or other person subject to this Act, or modification or cancellation thereof, to which it may be a party or conform in whole or in part, fixing or regulating transportation rates or fares; giving or receiving special rates, accommodations, or other special privileges or advantages; controlling, regulating, preventing, or destroying competition; pooling or apportioning earnings, losses, or traffic; allotting ports or restricting or otherwise regulating the number and character of sailings between ports; limiting or regulating in any way the volume or character of freight or passenger traffic to be carried; providing warehousing, docking, or other terminal facilities; providing that the one carrier shall act in any manner as agent or representative of the other carrier; or in any manner providing for an exclusive, preferential, or co-operating working arrangement.

"(b) Every common carrier by water shall file immediately with the board a true copy, or, if oral, a true and complete memorandum, of every agreement with a common carrier by railroad subject to the provisions of the Interstate Commerce Act, as amended, or modification or cancellation thereof, to which it may be a party or conform in whole or in part, relating to the interchange of freight or passengers, or the making of joint or through rates, or providing warehousing, docking, or other terminal facilities, or providing that the one carrier shall act in any manner as agent or representative of the other carrier, or in any manner providing for a co-operative working arrangement between the two carriers. In all such cases the common carrier by railroad shall also have a like duty. The provisions of this subdivision shall apply only to agreements relating to passengers or property transported or to be transported to or from a foreign country or the Philippine Islands from or to a port or other place in the United States.

"(c) The term 'agreement' as used in this section includes understandings, conferences, and other arrangements.

"(d) The board may by order disapprove, cancel, or modify any agreement, or any modification or cancellation thereof, whether or not previously approved by it, that it finds to be unjustly discriminatory or unfair as between carriers, shippers, exporters, importers, or ports, or between exporters from the United States and their foreign competitors, or to operate to the detriment of the commerce of the United States, or to be in violation of law or to be otherwise detrimental to the interests and welfare of the United States, and shall approve all other agreements, modifications or cancellations.

"(e) Agreements existing at the time of the enactment of the Merchant Marine Act, 1922, shall be lawful until disapproved by the board. It shall be unlawful to carry out any agreement or any portion thereof, disapproved by the board.

"(f) All agreements, modifications, or cancellations, made after the enactment of the Merchant Marine Act, 1922, shall be lawful only when and as long as approved by the board, and before approval or after disapproval it shall be unlawful to carry out in whole or in part, directly or indirectly, any such agreement, modification, or cancellation.

"(g) Every agreement, modification, or cancellation, lawful under this section, shall be excepted from the provisions of the Act entitled 'An Act to protect trade and commerce against unlawful restraints and monopolies,' approved July 2, 1890, and amendments thereof and Acts supplementary thereto, and the provisions of sections 73 to 77, both inclusive, of the Act entitled 'An Act to reduce taxation, to provide revenue for the Government, and for other purposes,' approved August 27, 1894, and amendments thereof and Acts supplementary thereto.

"(h) Whoever violates any provision of this section shall be liable to a penalty of $1,000 for each day such violation continues, to be recovered by the United States in a civil action."

SEC. 606. Paragraph (d) of paragraph (13) of section 6 of the Interstate Commerce Act, as amended, is amended to read as follows:

"(d) If any carrier by railroad subject to this Act enters into arrangements lawful under section 15 of the Shipping Act, 1916, as amended, with any carrier by water operating from a port in the United States to a foreign country, for the handling of through business between interior points of the United States and such foreign country, the commission may require such carrier by railroad to enter into similar arrangements with any or all other carriers by water operating from such port to the same foreign country, but such arrangements shall be subject to the provisions of section 15 of the Shipping Act, 1916, as amended."

JOINT OR PROPORTIONAL RATES

SEC. 607. Section 28 of the Merchant Marine Act, 1920, is amended to read as follows:

"SEC. 28. (a) That no common carrier shall charge, collect, or receive, for transportation subject to the Interstate Commerce Act, as amended, of passengers or property, under any joint rate, fare, or charge, or under any export, import, or other proportional rate, fare, or charge, which is based in whole or in part on the fact that the passengers or property affected thereby are to be transported to, or have been transported from, any port in a possession or dependency of the United States, or in a foreign country, by a carrier by water in foreign commerce, any lower rate, fare, or charge than that charged, collected, or received by it for the transportation of passengers, or of a like kind of property, for the same distance, in the same direction, and over the same route, in connection with commerce wholly within the United States, unless the vessel so transporting such passengers or property is, or unless it was at the time of such transportation by water, documented under the laws of the United States.

"(b) Whenever the board is of the opinion, however, that adequate shipping facilities to or from any port in a possession or dependency of the United States or a foreign country are not afforded by vessels so documented, it shall certify this fact to the Interstate Commerce Commission, and the commission shall, by order, suspend temporarily the operation of the provisions of this section with respect to the rates, fares, and charges for the transportation by rail of passengers and property transported from, or to be transported to, such ports.

"(c) Such suspension of operation of the provisions of this section shall be terminated upon 30 days' notice, given in accordance with the requirements of section 6 of the Interstate Commerce Act, as amended, by order of the commission whenever the board is of the opinion that adequate shipping facilities by such vessels to or from such ports are afforded and so certifies to the commission.

"(d) Whenever the board and the commission are both of opinion, and certify, that putting into effect or keeping in effect the provisions of this section will result in unjust discrimination between ports of the United States on commerce accustomed to move through such ports or in materially changing the channels of transportation within the United States, or in unduly congesting one or more of the ports of the United States, the commission shall, by order, suspend the operation of said provisions until such time as it and the board reach a contrary conclusion in the premises, whereupon such suspension shall, by order, be terminated by the commission upon 30 days' notice as hereinbefore provided for the termination of other suspensions."

TITLE VII—MISCELLANEOUS PROVISIONS

TRANSPORTATION BY WATER OF GOVERNMENT OFFICIALS

SEC. 701. Any officer, employee, or agent of the United States, including legislative, judicial, diplomatic, and consular officers, and officers serving in the military or naval forces of the United States, travelling by water, when the expense of such passage is chargeable directly or indirectly to the United States, shall, when practicable travel in a public vessel of the United States or a vessel registered, or enrolled and licensed, under the laws of the United States. When passage in such a vessel is not practicable, the voyage may be made in a vessel under a foreign flag only when specifically ordered by the head of the department or other Government establishment concerned or upon order specifically approved by such head of department or other Government establishment, who shall as promptly as possible report each such voyage made in a vessel under a foreign flag, together with the reasons showing necessity therefor, to the board.

(b) Any person subject to the provisions of subdivision (a) who fails to comply therewith in respect to the passage taken shall not be reimbursed for such passage money, or shall be surcharged in his accounts with the United States with the amount thereof, as the case may require.

TRANSPORTATION OF GOVERNMENT SUPPLIES

SEC. 702. All goods, wares, merchandise and material of every nature (including supplies for the military or naval forces of the United States) belonging to or intended for the United States, transported by water, shall when practicable be shipped in a public vessel of the United States or a vessel registered, or enrolled and licensed, under the laws of the United States. When shipment in such a vessel is not practicable and the shipment is made in a vessel under a foreign flag, it shall be the duty of the officer, employee or agent of the United States authorizing or making the shipment, within one month thereafter, to mail a written notice to the board, stating the ports of departure and destination, the date, the name of the vessel, and the reason why the shipment was not made in a public vessel or a vessel registered, or enrolled and licensed, under the laws of the United States.

REGULATIONS

SEC. 703. Except where otherwise specifically provided in this Act, the board may make such regulations in respect to matters placed under its jurisdiction by this Act as it deems necessary in order to make effective the intent and purposes of this Act.

SEPARABILITY

SEC. 704. If any provision of this Act or the application thereof to any person or circumstance is held invalid the validity of the remainder of the Act and of the application thereof to other persons and circumstances, shall not be affected thereby.

SHORT TITLE

SEC. 705. This Act may be cited as the "Merchant Marine Act, 1922."

Developments in Marine Insurance

Restrictive Clauses Troublesome—Hague Rules—More Board Vessels Rated—Rules for Inland Craft—Syndicates Praised

By "Bordereaux"

FROM the viewpoint of the underwriter there is a decided danger in the use of limiting clauses that restrict the liability of the carrier. Considerable interest has recently been taken in a clause used in connection with shipments of cotton and which has been inserted in ocean bills of lading by steamship companies operating out of New Orleans. It reads as follows:

"All risks of fire, flood, high water, rain, collapse of wharf, or any other causes not happening through the fault or negligence of the owner, master, or agent of the vessel occurring prior to actual loading aboard vessel, to be borne by the owner of the goods whether or not actually receipted for by vessel or agent."

Underwriters insist that carriers are unquestionably beyond their rights in making use of such a clause, as Section I of the Harter Act prohibits the use of clauses limiting the liability of the carriers with respect to the care and custody of cargoes and, if the damage to the cotton is in any way due to the fault of the carrier, even though the floods are partially responsible, the carriers should not be allowed to evade their liability by hiding behind such a restriction. It will readily be seen that the question of the negligence of the carrier could not be subsequently raised in court, if the shipper could be shown to have had knowledge of this clause and so to be bound by it.

Assureds, holding open policies on cotton, have been advised by their underwriters that this clause is not only a violation of the contract between carrier and shipper but that it is in violation of the policy clause which reads, "Warranted by the assured that they will not relieve any carrier or other bailee from any statutory or common law liability or duty." It is of prime importance for the shipper thoroughly to understand the seriousness of this contract obligation, for such a breach of warranty renders the policy voidable at the option of the underwriter.

Furthermore, there is no occasion for the carrier to employ such a clause for his own protection as he has a perfectly sound defense in event of a claim for flood damage; under the common law he cannot be held liable for damage by floods, as it is one of the so-called acts of God, nor is he made liable by statute—hence the suspicion of the underwriters that there was some ulterior purpose behind the introduction of the obnoxious clause.

The bailee clauses in marine insurance policies are broad in their provisions, but their intent has been to prevent the carrier from taking advantage of the shipper's insurance and thereby limiting the legal liability of the former. The trouble with some bailee clauses is that they are so restrictive that, if construed technically, the assured would have no coverage whatever. Most underwriters, however, follow a bailee clause with a saving clause wherein the underwriter agrees to pay the claim of the assured, if caused by an insured peril, provided the assured is able to collect the same from the carrier.

The Hague Rules

UNQUALIFIED endorsement of the Hague Rules, 1921, has made little progress in this country of late. They were let down by the National Foreign Trade Convention with the mildest kind of an acknowledgment and a suggestion of further study, while the United States Chamber of Commerce contented itself with a qualified endorsement of them as "a step in advance" and a request of Congress to enact legislation for the rules "with such interpretations as may be deemed necessary." Opponents of the rules insist that they are obscure and will have to be clarified before they can be endorsed; and, further, that care must be taken that international uniformity be not secured at the price of national interests. This point was carefully emphasized in the resolution adopted at the recent annual meeting of the National Association of Manufacturers, in New York, when the rules were approved as "a practical step forward," to which was added the significant qualification, "but not as a final substitute for highly desirable national legislation fortified by international agreements."

In his address before the Ninth National Foreign Trade Convention, President Benjamin Rush, of the Insurance Company of North America, observed:

"I am not in favor of the Hague Rules in their present form. They are defective in that they deal only with the responsibility of the shipowner while the goods are on board of his ship, and fail to deal with his responsibility while the goods are in his custody but not actually on the ship. They do not apply to deck cargoes . . . . When properly amended, as indicated above, they will be a step in advance over the conditions now prevailing, but they still fall far short of the full protection to which innocent cargo is entitled at the hands of the shipowner. They will, therefore, be in the nature of a compromise between conflicting interests and they should not therefore cause any cessation in the efforts made by merchants and shippers to reimpose upon carriers full responsibility for losses resulting by their negligence or the negligence of their servants."

More Board Vessels Rated

MARINE underwriters announce progress in their cooperative work in connection with the Shipping Board in the matter of readjusting steamer classifications for cargo rating purposes. All Board vessels of the twin-screw passenger type, not over 20 years old, are to be recommended for first class liner classifications. These proposals refer to vessels operated by four lines—the United States Lines, Pacific Mail, Pacific Steamship Company and the Munson Line. The daily papers were incorrect in announcing that all Board vessels would receive preferential classifications. This is not the case, nor that all twin-screw passenger vessels henceforth brought into use will be so classed. The steamship lines above mentioned are operating several former German owned steamers more than 20 years of age which will not benefit by the underwriters' recommendations.

Writing the "Majestic" Class

IT will readily be credited that the great interest aroused at the port of New York by the first appearance of the *Majestic*, the largest vessel afloat, was vividly shared by marine underwriters. Much sage council was passed along by the veterans of the profession anent the hazards that enter into the insuring of such tremendous ships as this. The laymen might be justified in concluding that a vessel so structurally perfect as the *Majestic* would offer the most

attractive kind of a risk for the insurer, and yet the average underwriter would much prefer a smaller boat. The very size of the *Majestic* makes her difficult to handle and this is of great importance to the underwriter when a vessel is entering or sailing from a port. Congested shipping conditions and narrow channels in the majority of the great ports make the danger of stranding and collision very real indeed. Vessels of the draft of the *Majestic* must come into New York on high tide, which means that, if such a ship is delayed by fog or other causes and arrives off Ambrose Channel and is compelled to anchor awaiting high tide or clearing of the fog, she may very easily drift on the shoals. When the *Majestic* encountered the swift tide off Quarantine she swung around at right angles, partially blocking the channel, which is only 1,800 feet wide at this point. It took skillful maneuvering to get her around so as to give sea room for the *Mauretania* to get by. Not only is the danger of stranding and collision materially increased in the case of large steamers, but the cost involved in getting such a monster off the strand would be decidedly greater than if it were a smaller vessel.

Rules for Inland Craft

RULES governing the construction of river, harbor and canal craft are under preparation by the American Bureau of Shipping, with a view of taking up the classification of the same. A number of vessels of these types have already been classed, and it has been found to be very advantageous to their owners in arranging their insurance on hulls and cargoes. Bureau officials are giving particular attention to the classification of the modern self-propelled barge and of tow barges, in view of the activity on the part of New York authorities in reviving interest in a more extended use of the Barge Canal. The Bureau, which is now located at 50 Broad street, New York, will welcome any suggestions from responsible builders, owners and underwriters with regard to these particular types of vessels, and will give such suggestions the most careful consideration and possibly include them in the forthcoming rules.

Short Policy Revised

THE American Institute of Marine Underwriters is giving consideration to the short form of marine insurance policy that has been the subject of so much discussion and revision during the last three or four months. Suggestions for alterations were received from a number of brokers whose criticism had been invited, and these suggestions have been considered with the result that recommendations for changes were sanctioned and the policy reprinted with the modifications included. It is to be hoped that the Institute will approve the recast document, as such a course would mark an important step toward the policy uniformity and simplicity so eagerly sought by banking and shipping interests. The new policy is intended also for use in insuring shipments to Great Britain, where the courts have ruled that consignees may demand the inclusion of actual policies, instead of the popular certificate, among C.I.F. papers.

"Endicott" Decision Reversed

A GREAT victory has been won by the Greater British Insurance Corporation, Ltd., of England, in the case brought against it by the Peninsular Transportation Company for contesting liability on the loss of the schooner *Charles G. Endicott*. The transportation company won a judgment last November for $5,000 and costs in the Special Term of the Supreme Court after the court had struck out the defendant's answer and given a summary judgment, without trial or consideration of the evidence for the plaintiffs. Appeal was taken to the Appellate Division of the Supreme Court and in an opinion concurred in by the entire court the orders appealed from are reversed, the plaintiff's motion to cut out the answer of the defendant and for judgment is denied, the insurance company's motion to vacate the judgment and for leave to file an amended answer is granted, and the judgment reversed with costs. The case now reverts to the lower court for retrial. The reversal was based both on evidence and on the extraordinary procedure of the court. This is the celebrated case in which after several of the American underwriters had paid their proportion of the loss the British companies contested liability, denying destruction by mines and alleging criminal collusion on the part of the owners in the destruction of the schooner off the coast of Cuba in February of last year.

Syndicates Officially Praised

SWEEPING commendation of the condition and achievements of the American Marine Insurance Syndicates has been accorded in the report of their examination by the New York Insurance Department, just filed. Albert N. Butler, who made the report, states that the Syndicates have accomplished what they were organized for, and pronounces their continued existence as an economic adjunct of the American merchant marine as eminently justified. Of Syndicate "A," which was organized for inspection damage and loss surveys of vessels of all types and classes, the report says that it has established an economical method of handling the operation and has become an important factor in securing repairs at much more reasonable figures than heretofore. It commends the low expense ratio maintained in the work of "B," which, inclusive of taxes and brokerage, reached but 12.44 percent of the earned premium. On account of larger brokerage allowances, the expense ratio of "C" was somewhat higher than that of "B," but even so it was but 21.29 percent of the earned premiums.

"There can be no doubt," reports Examiner Butler, "that Syndicate 'C' offers for the first time to the American market hull insurance adequate to meet practically all American requirements. The syndicates have, therefore, met the wishes of the Committee on Merchant Marine and Fisheries by providing greater American hull coverage . . . . It is a great convenience to brokers to be able to deal through the syndicates, thus quickly covering the capacity of the American market . . . . Economically, the underwriting syndicates appear to be highly successful. There are numerous necessary and expensive operations formerly duplicated by the various underwriters, that are now co-ordinated under the one head—underwriting, adjusting, surveying, settlements, etc. The expenses of the syndicates have been markedly low. Furthermore, there should be gathered under this one organization a mass of invaluable experience in regard to ships, owners and operators which must ultimately be extremely beneficial to efficient service to the assured and also the American mercantile marine . . . . As regards Syndicate 'A,' this organization may well develop into the powerful institution contemplated by its sponsors . . . . Should the profits indicated in the foregoing statement continue over a considerable period and, if such profits are found ultimately to represent economies effected by the syndicates, reduced rates of insurance to American shipowners should soon follow."

American Farmers and American Ships

(*Continued from page* 412)

France have come back to their home towns and farms with a new realization of what ships and more ships mean in peace and war to America. Those foreign foes of the American merchant marine who protest that all American farmers are opposed to a merchant marine of our own and will help Europe re-clinch her old monopoly of our ocean trade, simply do not know those farmers or their sons!

S. S. Moreton Bay—First of the Australian "Bay" Fleet

New Australian Liner Moreton Bay

Passenger and Cargo Vessel of 23,320 Tons Displacement to Operate Between the United Kingdom and Australia

ONE of the interesting post war developments of intercontinental passenger service is the construction of five combination passenger and freight vessels for operation between the United Kingdom and Australia. These vessels will be operated by the Australian Government Commonwealth Line and will be known as the "Bay" fleet. The *Moreton Bay* is the first of this fleet to be completed, the others being *Hobson's Bay, Jervis Bay, Largs Bay* and *Esperance Bay*.

On account of the long voyages these ships will have to make and the variations of temperature through which they will pass it was necessary to give special consideration to passengers and their comfort and in consequence a high standard of accommodation has been provided which has also been extended to include the crew's quarters and provide a maximum of comfort for them as well as the passengers.

The following particulars of the *Moreton Bay* will also apply to the sister ships.

Length over all	548 feet 9 inches
Length between perpendiculars	530 feet 0 inches
Breadth molded	68 feet 0 inches
Depth, molded, to shelter Deck "B"	43 feet 6 inches
Draft	29 feet 11½ inches
Displacement	23,320 tons
Sea speed in loaded condition	15 knots

The vessel is classed 100 A-1 at Lloyds, shelter deck with freeboard and was also built to satisfy the British Board of Trade requirements for passenger ships and, in addition, to comply with the Australian Navigation Act.

Hull

The new vessels have a forecastle forward and a long bridge amidships. Two pole masts are fitted and one funnel. Including the boat and bridge decks, there are six decks in the depth of the vessel, the upper decks being utilized for passenger accommodation and the lower decks and main holds for cargo.

A special feature of the construction is the large capacity of insulated space provided in numbers 2, 3, 4 and 5 holds and D and E 'tween decks. General cargo will be carried in numbers 1 and 6 holds and the 'tween deck spaces above on D and E decks.

Refrigerated Spaces

The refrigerated compartments are insulated by cork slabs embedded in bitumen and faced with a magnesite cement

which is proof against vermin or damp and preserves airtightness. These spaces will be utilized for the carriage of frozen meat, butter, eggs, rabbits, fruits, etc. In view of this and the fact that some of these must be carried at higher temperatures than others, the brine distribution is arranged on the three temperature system, by means of which brine for freezing or chilling and for thawing out can be supplied independently to each brine pipe section throughout the ship. Consequently each refrigerated space is controlled independently of all others according to the requirements of the cargo carried.

ACCOMMODATIONS

The new "Bay" ships are designed primarily to carry third class passengers but special first class cabins for 12 passengers have been provided on the bridge deck. These cabins are elaborately designed and furnished and each is arranged to include a private bathroom.

Third class accommodations for 720 passengers are provided practically the entire number of which are located on "C" deck. These accommodations are arranged in 2, 4 and 6 berth cabins and in the two foremost and two aftermost compartments the accommodations are portable so that when not required for passengers these spaces may be utilized for cargo. Access is gained to the third class accommodations through entrances erected on the shelter deck which also are fitted with lavatories, bathrooms, etc., for the passengers' use.

The public rooms are located on the shelter deck in way of the bridge superstructure. A large dining room is provided at the forward end and arrangements made for seating 350 passengers at one time. Right aft of the main dining room are arranged the pantries and galleys and directly abaft the galley are located accommodations for stewards, butchers, bakers, cooks, etc. The after end of the bridge enclosure is fitted up with a social hall on the port side and a smoking room on the starboard side, each of these public rooms having an open but protected veranda fitted directly abaft them. All of the public rooms are specially designed to provide for the greatest comfort and entertainment of the passengers, a feature which is most essential on long sea voyages, especially through tropical waters.

On the shelter deck aft, located so as to be completely isolated from all other erections, are hospitals consisting of separate rooms providing for male and female cases or for special cases requiring complete isolation. A special bathroom is provided for each ward and each is equipped along the most modern lines.

The captain's quarters are located forward on the boat deck and aft on the same deck in way of the engine room casing accommodations are provided for the firemen, these latter being arranged in a manner which enables the men to proceed to their work without using the passenger decks.

Third Class Smoking Room

First Class Dining Room

The ship's officers, doctor and purser are berthed on the bridge deck forward and the engineers on the bridge deck aft in way of the engine casing and No. 4 cargo hatch.

The crew is berthed in well ventilated, roomy quarters under the forecastle.

BOILERS

Steam is generated in three double ended and two single ended boilers designed for a working pressure of 220 pounds per square inch and arranged in a single boiler compartment. The boilers are of the multitubular return tube type fitted with smoke tube superheaters and Howden's forced draft.

Arrangements have been made to burn oil fuel but the necessary gear is carried for converting to coal burning should the necessity arise.

MAIN PROPELLING MACHINERY

The main propelling machinery consists of turbines of the Parson's reaction type driving twin screws through double reduction gearing. The installation is rated at a collective shaft horsepower of 9,000 with the propeller revolutions about 90 per minute. The astern power is approximately 63 percent of the full power ahead. The high pressure pinion of the first reduction gearing is driven through a flexible coupling by one stage of impulse blades at the forward end of the high pressure turbine and the low pressure pinion is driven through a flexible coupling by the low pressure turbine. The unit is designed to operate with 100 degrees F. of superheat at the high pressure inlet.

Adjusting blocks of the Michell type are fitted to the turbines.

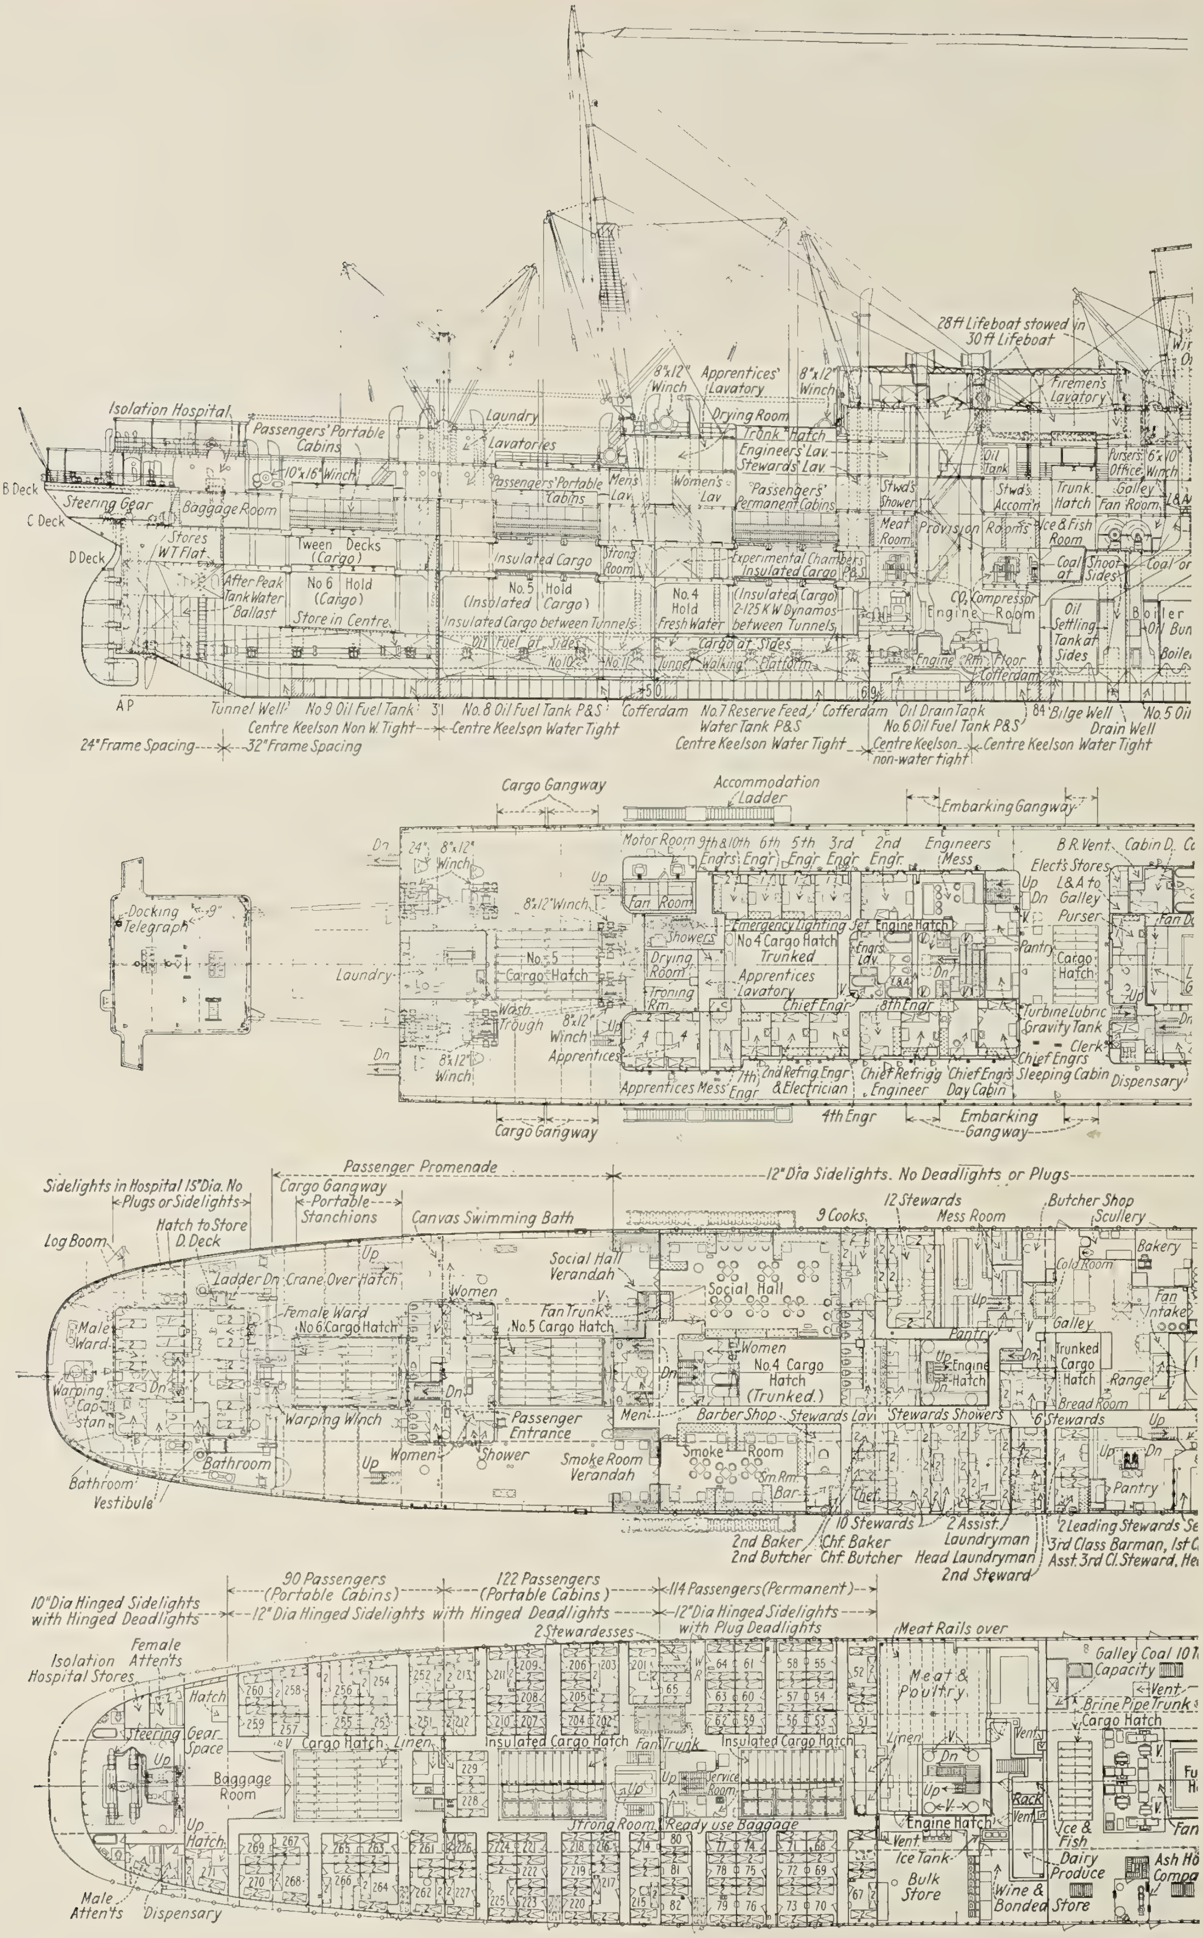
The reduction gearing is of the helical type, the main gear wheel consisting of a cast iron center portion upon which a heavy forged steel rim is shrunk and first and second reduction pinions or forged nickel steel. Forced lubrication is used for the turbines, shaft bearings and gearing.

Thrust blocks of the Michell type are fitted adjacent to the reduction gears.

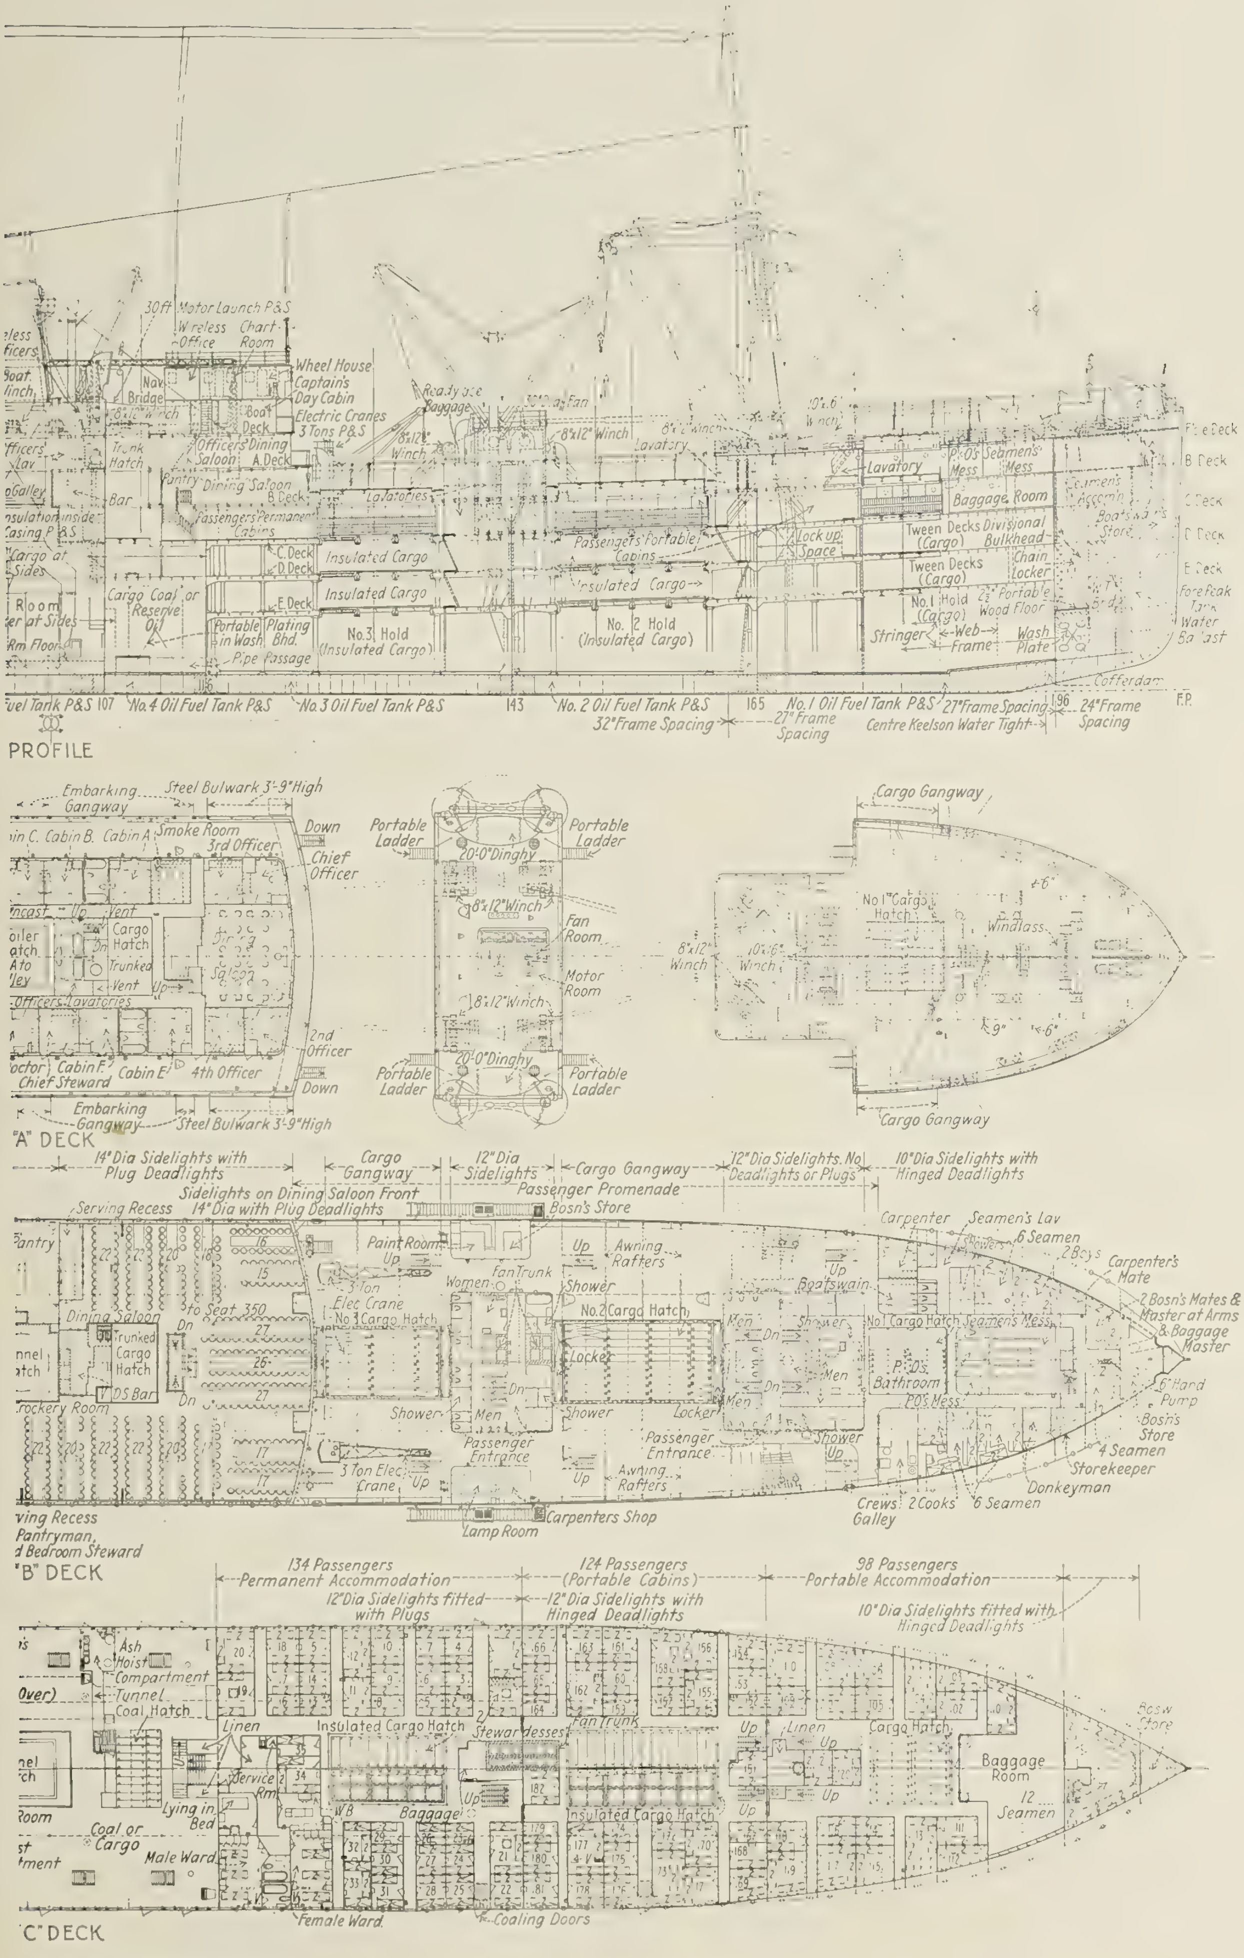
The condensing plant installed is capable of maintaining a vacuum of 28 inches when the engines are operating continuously at full speed with a barometer of 30 inches and sea water at 80 degrees F. The main condensers are of the "Contraflo" type underslung on the low pressure turbines so that the low pressure turbine is always free from drainage water. The vacuum system embodies all the latest improvements for economical and efficient operation in conjunction with the feed heating system. "Contraflo" marine specialties are provided throughout.

The auxiliary condenser is also of the "Contraflo" vacuum type, and the auxiliary feed system is similar to the main system.

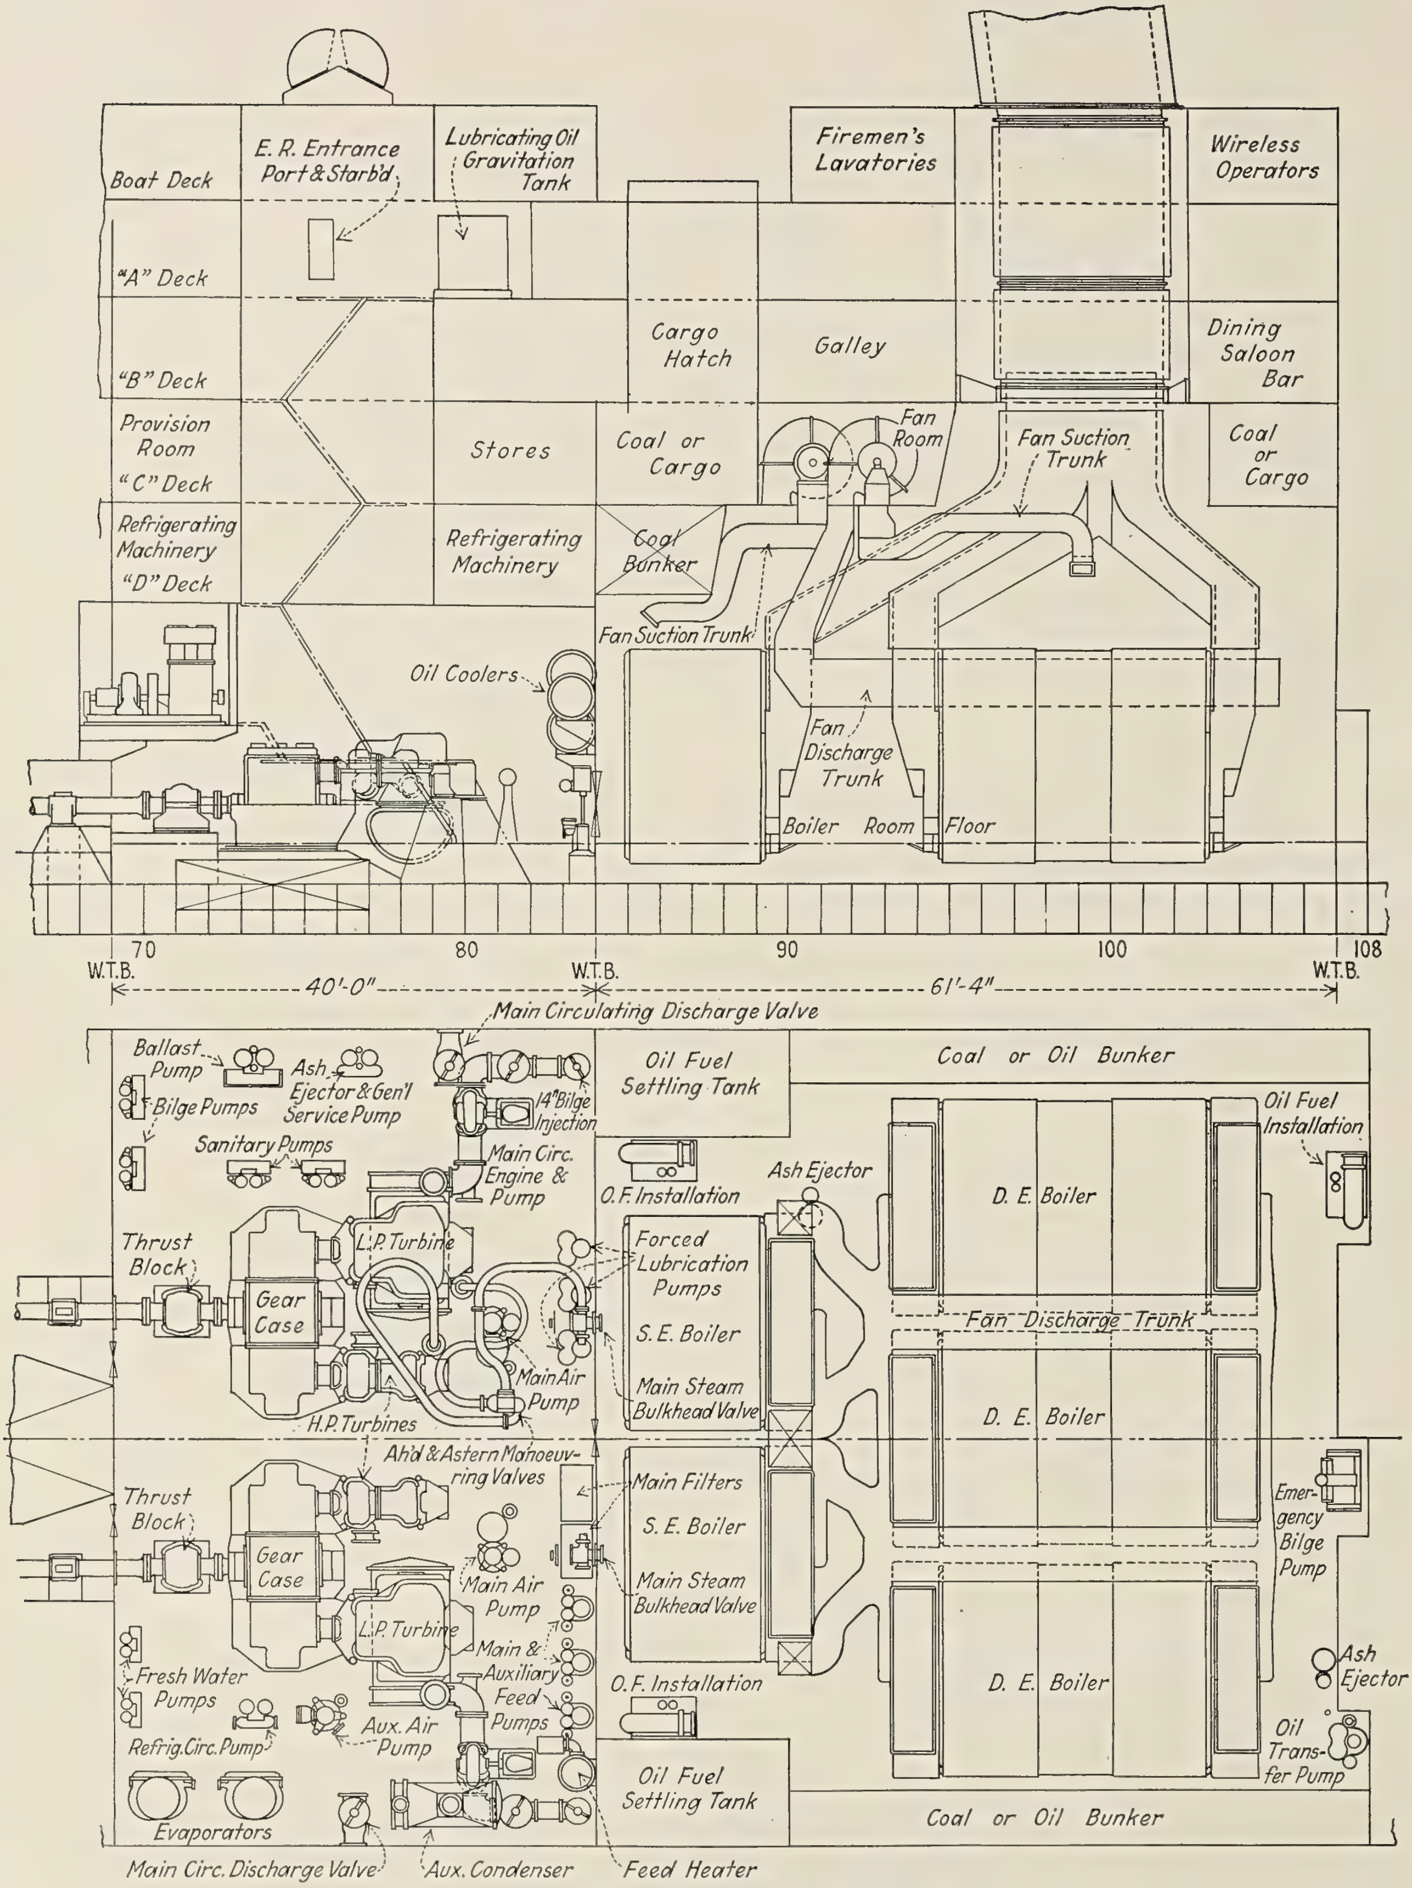
The turbine turning gear is operated by electric motors



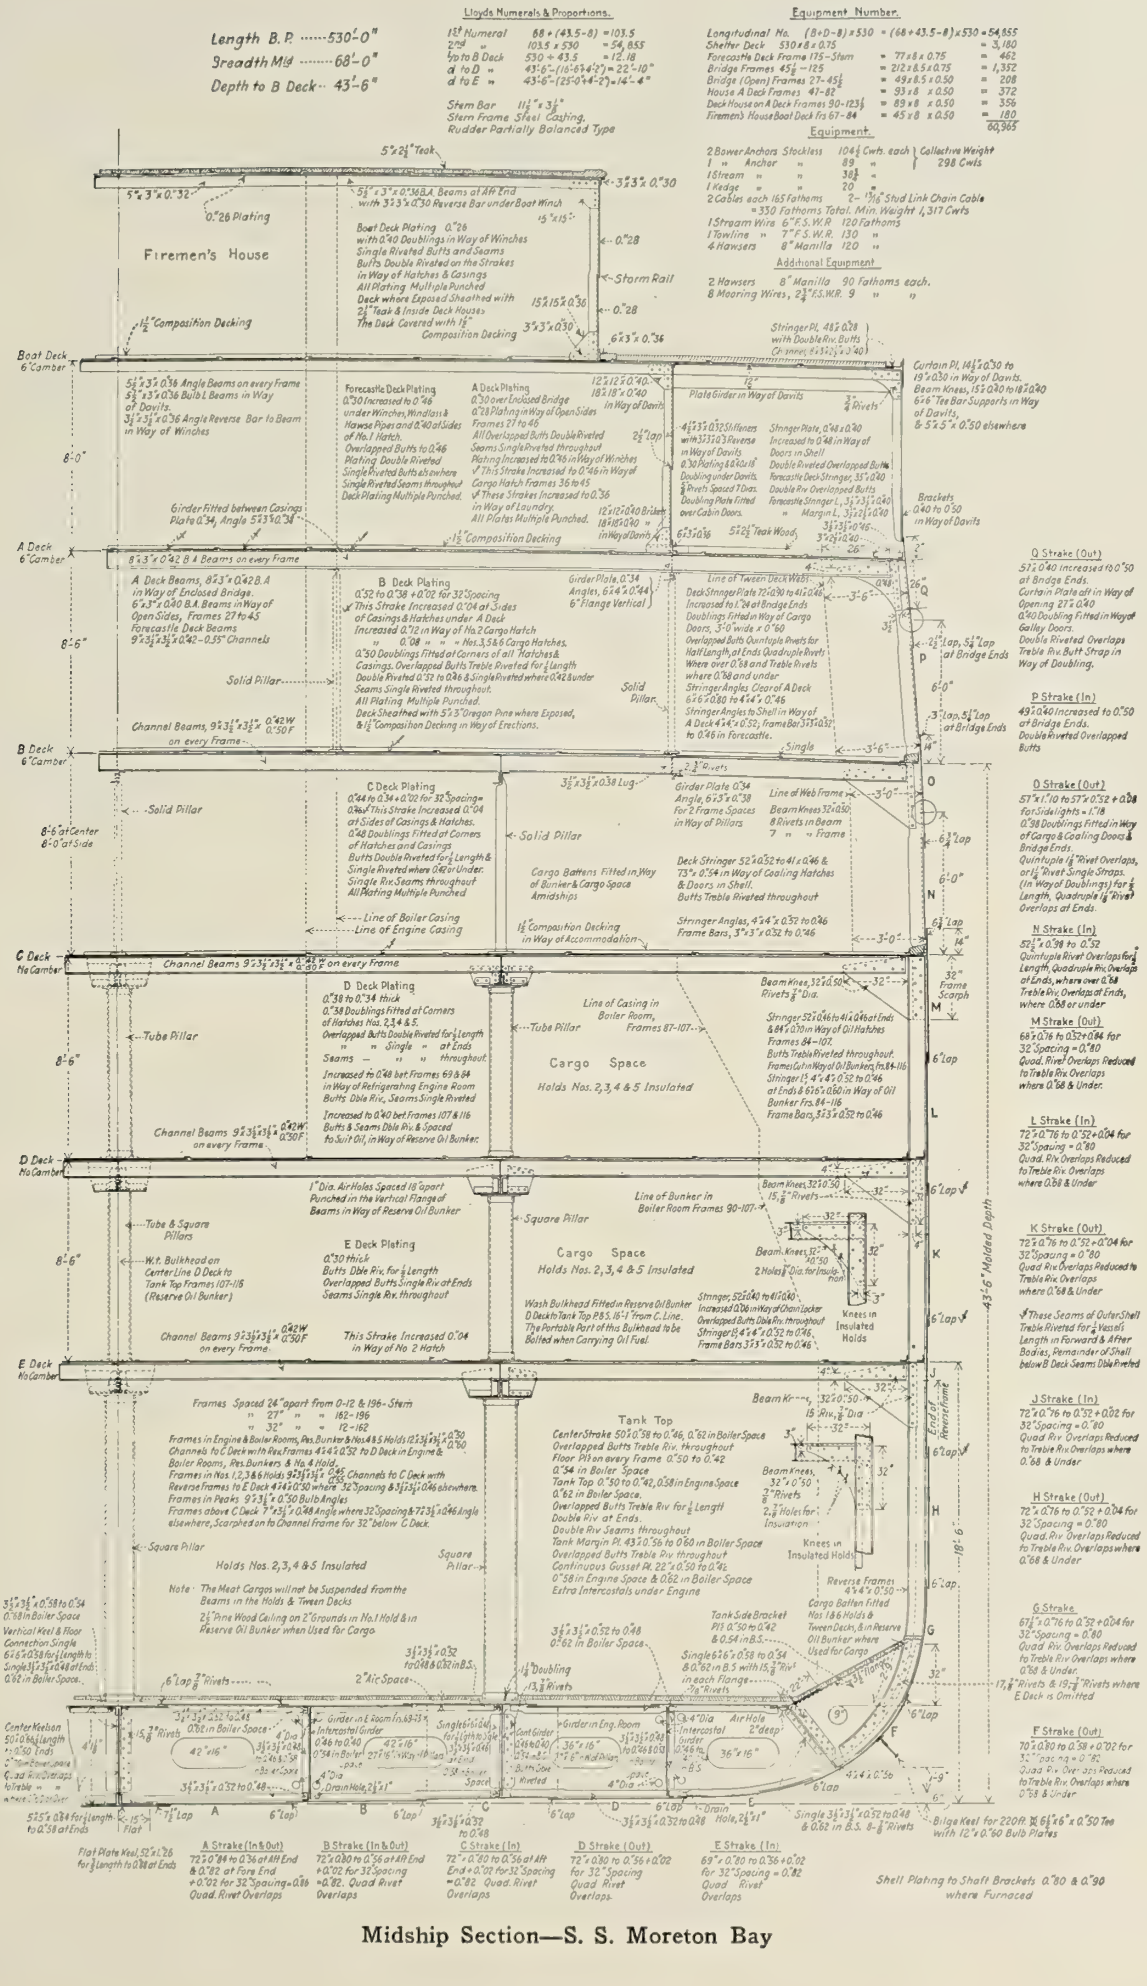
General Arrangement Plans



of S. S. Moreton Bay



Machinery Arrangement, S. S. Moreton Bay



Midship Section—S. S. Moreton Bay

and is arranged above the floor in order to provide the greatest accessibility.

Vickers system of lubrication is used in way of the stern tubes.

Four bladed propellers of the built-up type are fitted, the manganese bronze blades being bolted to a cast steel hub.

All valves on the superheated steam lines are made of cast steel with forged steel fittings and valve faces of nickel alloy.

Safety Provisions

Every attention has been given to providing means for reducing the risk at sea and providing the most modern facilities for insuring the safety of passengers.

In general, the subdivision of the vessel complies with the full requirements laid down by the International Convention for the Safety of Life at Sea. Watertight doors located below the waterline are arranged so that they may be operated both by hand and by the Stone hydraulic system from the bridge or from either side of the bulkhead at the door itself. Fire bulkheads have also been arranged in the superstructure as required by the "Convention" and in the event of fire in any compartment, that compartment can be effectively isolated until the fire is extinguished.

A water service system for fire extinguishing purposes and a special steam fire extinguishing system for the main holds, with connections for steaming out double bottom and fuel oil tanks, is also fitted. Special fire extinguishers are also fitted in racks throughout the several compartments in accordance with the rulings of the "Convention."

Sea risks have been further reduced by the provision of lifeboats sufficient to accommodate the ship's full complement. The boats include:

Two 30-foot motor launches equipped with wireless,
Six 30-foot lifeboats,
Six 28-foot lifeboats,
Two 20-foot dinghies.

Lifeboat davits of the Australis type have been fitted.

Life jackets and life buoys are available throughout the accommodations and a powerful wireless installation is carried on the boat deck.

Cargo Handling Gear

Special attention has been given the cargo handling gear fitted aboard the *Moreton Bay* as efficient cargo handling is essential to economical operation of any vessel and particularly in a vessel handling refrigerated or similar perishable cargoes.

The cargo and derrick gear of the *Moreton Bay* have been designed to eliminate lost motion. The gear includes 18 tubular steel derricks of 5 tons capacity, four of 3 tons and one designed to handle heavy loads up to 35 tons. The arrangement provides for four booms stepped on tables at each mast, the 35-ton derrick being stepped on the forecastle deck at the base of the foremast and the remaining booms stepped on derrick posts which are fitted with cowls and also utilized as ventilators. Two 3-ton electric cranes are installed on "B" deck in front of the bridge.

A total of 23 winches has been provided and distributed as follows:

One, 16 by 10 inches, aft, for warping purposes
Two, 16 by 10 inches, on forecastle for warping, handling cargo, and operating the 35-ton derrick
Eighteen, 8 by 12 inches, located in way of cargo booms
Two, 6 by 10 inches, for operating cargo booms

Six of the cargo winches on the boat deck are specially adapted for working 8 "Maces" boat winches through a chain drive.

Auxiliary Machinery

A steam windlass of high power and speed, with nigger heads on each side for warping, is located on the forecastle.

One steam capstan, 12½ by 10 inches, is fitted aft.

The steering gear is of the Vickers electric hydraulic type consisting of two complete gears, each operated by a Williams-Janney variable delivery pump and controlled from the navigating bridge by means of a telemotor installation.

The refrigerating machinery consists of two horizontal, compound, marine type engines, 14 by 26 inches diameter by 21 inches stroke driving one horizontal double acting CO_2 compressor. These machines, together with the necessary gas condensers, separators, circulating pumps, etc., are erected on "D" deck over the engine space.

Ventilation in the insulated holds and 'tween decks, when carrying fruit, is accomplished by the installation of four large Sirocco fans. The ventilation of the passenger and crew accommodations is effected by natural means and additional cowl ventilators are supplied for exhaust from the holds.

Fresh water storage tanks are constructed between the shaft tunnels and in addition large fresh water tanks are located over the firemen's quarters on the boat deck.

An emergency lighting set, operated by a Diesel oil engine and having a 35-kilowatt capacity, is located in a house above "A" deck and used to supply current for lighting the vessel in the event of a breakdown of the main generators.

Steam heating is provided for throughout the vessel, radiators installed in the various compartments being arranged so that the temperature may be regulated to suit those occupying the compartments.

In all, the vessel constitutes a most skillfully designed structure, both from the aspect of its special trade and particularly with regard to the comforts and conveniences of the accommodations for both passengers and crew.

The *Moreton Bay* was constructed in the shipyard of Messrs. Vickers, Ltd., at Barrow-in-Furness and to this yard was also awarded the contract for the *Hobson's Bay* and *Jervis Bay*. Contracts for the *Largs Bay* and *Esperance Bay* were awarded the William Beardmore & Company, Ltd., of Dalmuir.

Electrically Operated Coal Barges in Service on San Francisco Bay

By Charles W. Geiger

TWO coal barges have recently been placed in operation on San Francisco Bay, which are operated by electric motors, current for same being generated by a gasoline engine driven generator.

The superstructure on these barges carries a trolley suspended from a beam and operating a grab bucket. A 16 horsepower motor operates the trolley back and forth along the track on the superstructure, a 30 horsepower motor raises the grab bucket and a 30 horsepower motor opens and closes the bucket. These motors are placed in the main engine room, which is of steel construction and occupies one end of the barge.

The superstructure carrying the track enables the trolley and grab bucket to be extended out over the coal in the hold of the barge, when the grab bucket is lowered, picks up a load of coal, is raised to the trolley and the trolley and grab bucket is moved to the center of the barge directly over a receiving hopper. When the bucket is opened the coal drops into this receiving hopper, which in turn discharges the coal into a skip or elevator bucket. This elevator bucket is then elevated by electric motor and when at the proper height automatically discharges its contents into a chute which leads into the bunker of the steamer.

One of the most novel features in connection with this barge is the control room, shown in Fig. 3. In the foreground can be seen the controls for the three motors operating the trolley and grab bucket. In this room there are telltale

Fig. 1.—General View of Electrically Operated Barge Delivering Coal to a Japanese Liner

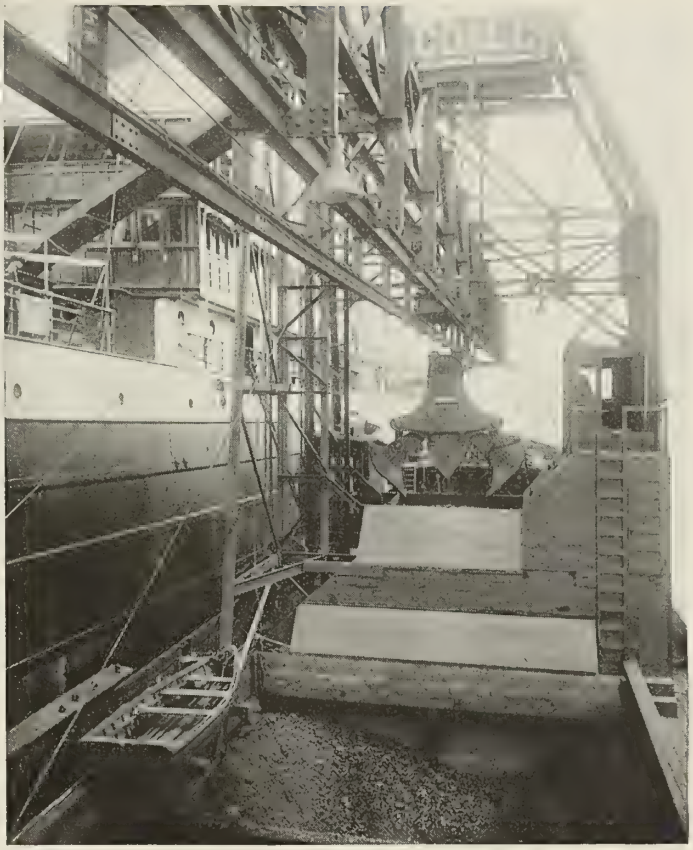


Fig. 2.—Close-up View of Barge Showing Grab Bucket in Action. No Shoveling Is Required

lights which enable the operator to know exactly where the grab bucket is without the necessity of looking, although he has an unobstructed view of the bucket at all times, the control room being provided with windows on three sides and with iron gratings in the floor.

After the operator opens the grab bucket, which delivers the coal into the central hopper, he opens a gate in the central hopper, which discharges the coal into the elevator bucket. When he is ready to discharge the elevator bucket into the bunkers of the steamer, the operator presses a button shown at *A* in Fig. 3 which raises the elevator bucket to the proper height, turns the bucket over so that the contents run into a chute, holds the bucket in this position (by means of a relay) until the coal has all been discharged into the chute, reverses the motor and lowers the elevator bucket to the proper position under the central hopper ready to receive another batch of coal. This is all done without any attention on the part of the operator, other than pressing the push button. It will be seen that there are three push buttons for the operation of the elevator bucket, one for the purpose of stopping the elevator bucket at any point and the other to reverse the elevator bucket.

There is a main switch in the engine room, which can be opened and closed by means of two push buttons in the control room. By this means the main switch can be opened or closed by the operator from the control room, making it unnecessary to operate the main switch by hand, although this is possible. In the control room there is an emergency switch operated by a push button. By pushing this button, every motor on the barge is instantly stopped. This is a very desirable "safety first" feature.

The generator is mounted on the engine bed and is direct connected to a four-cylinder, 125 horsepower gasoline engine, operating at 280 revolutions per minute. Distillate is used for fuel, only ten gallons being required per hour when the barge is operating at full capacity. Each barge

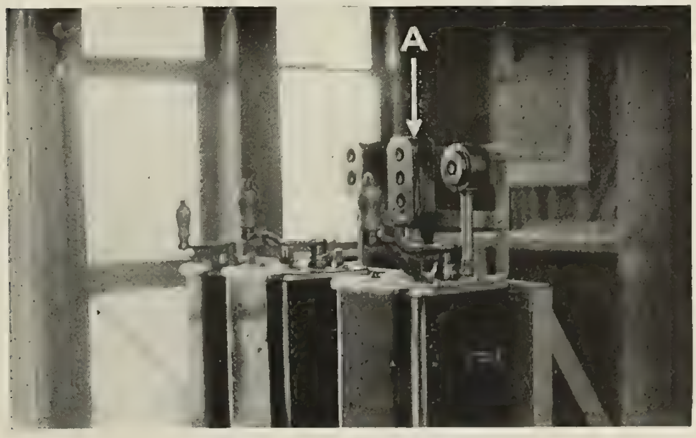

Fig. 3.—Control Room

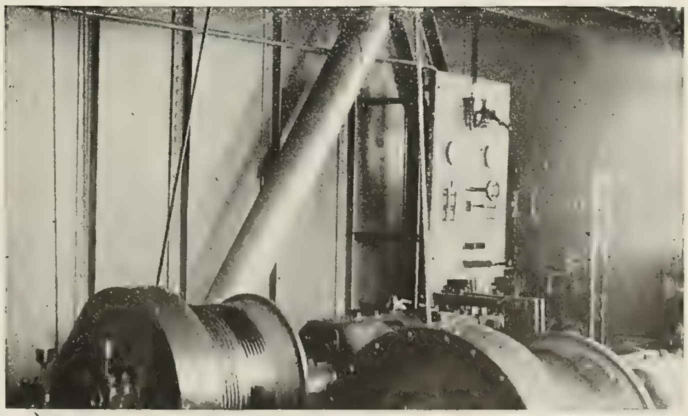

Fig. 4.—Engine Room, Showing Main Switchboard

has a capacity for delivering 100 tons of coal per hour into the bunkers of steamers.

In connection with these barges there is operated a traveling gantry crane electrically driven. The rails on which the crane runs have a gage of 200 feet. The length of travel along the bulkhead is 550 feet, current for operating the motors being obtained by a third rail system. This gantry bridge is equipped with a grab bucket capable of picking up two tons. This is used in discharging coal from cars. There is an extension out over the water by means of which the coal can be delivered direct from cars to the barges, or from the storage pile to the barges. This gantry crane is also used for handling crushed rock and sand from barges to cars or to storage yard.

New Mooring and Maintenance Tenders in Service in Mexican Waters

Of the two duplicate steel mooring and maintenance tenders recently designed by Whittelsey and Whittelsey, naval architects, of New York, and built by Kyle and Purdy, City Island, New York, the *Toteco,* owned by the International Petroleum Company of New York, has been in service in Mexico continually for about eight months, and the *Tacomonte,* owned by the Atlantic Gulf Oil Company of New York, has recently arrived and gone into service in the same waters. Both vessels are classified by the American Bureau of Shipping.

As these vessels are required for almost constant service for the maintenance of sea loading stations, including repairs to pipe lines, mooring buoys, etc., their design and construction are very rugged throughout and the machinery and equipment are laid out with the idea of simplicity and accessibility in order that the operation and any necessary repairs may be carried out with the facilities at hand. This service requires accommodations for rather a large mooring and maintenance crew, provided for in the forecastle, aside from the ship's crew, which is housed in the deck house.

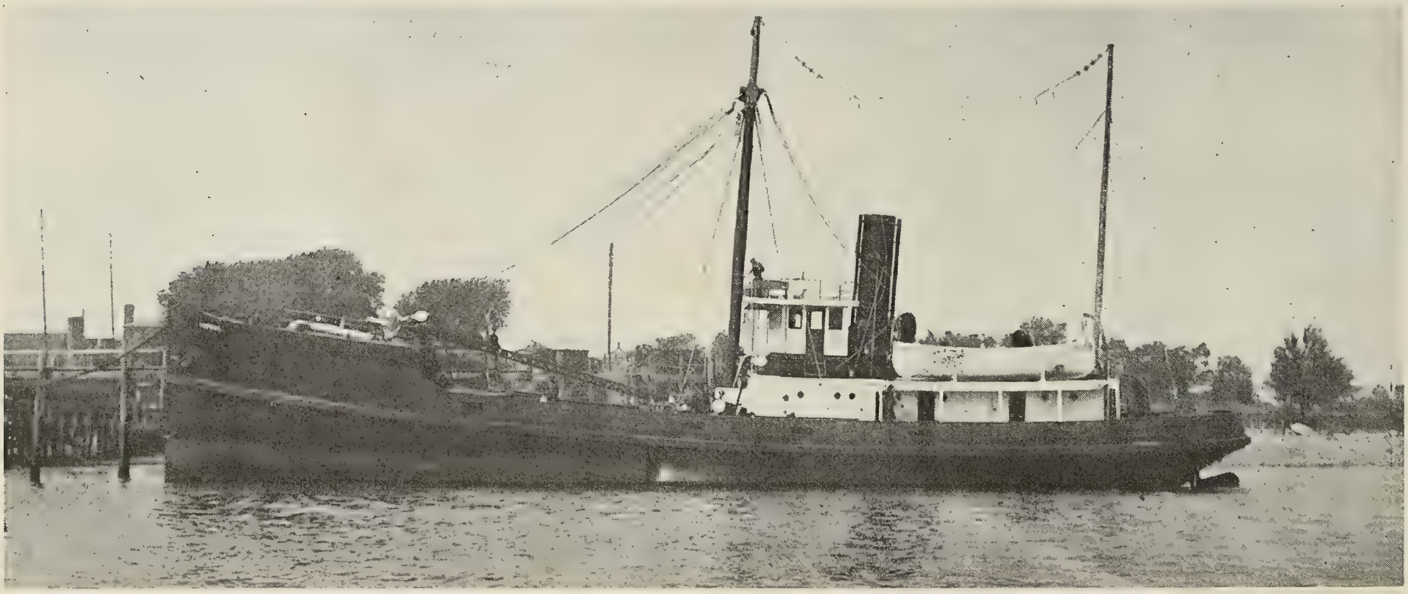
The principal dimensions of the vessel are as follows:

Length overall	133 feet 8 inches
Length on load waterline	126 feet 9 inches
Beam, molded	32 feet 0 inches
Depth	14 feet 6 inches
Draft (mean)	10 feet 6 inches
Draft (maximum)	11 feet 0 inches

The hull is of steel, with steel decks and deck houses and a wooden wheel house. Propulsion is by a four-bladed propeller driven by a surface condensing compound engine with cylinders 18 and 38 inches in diameter and 26 inches stroke developing 500 indicated horsepower at 105 revolutions per minute. Steam is supplied by a two-furnace Scotch boiler having 2,000 square feet of heating surface and equipped with the Todd fuel oil burning system and forced draft. The main condenser has 1,000 square feet of cooling surface and the engine room auxiliaries comprise a hot well, Reilly feed water heater, two vertical feed pumps, fire and bilge pumps, centrifugal circulating pump, sanitary pump, fresh water pump, air pump, injector, syphon and fuel oil set, all steam driven.

For handling heavy weights there is a steel derrick operated by twin Lidgerwood hoists. The falls, of Durable wire rope, have a capacity of 15 tons on a seven part line. The deck machinery includes a Hyde steam windlass and steam steering gear. Adjacent to the galley is a 1 ton Brunswick, steam driven, direct expansion, refrigerating machine. Electricity for lighting is supplied by a 10 kilowatt General Electric steam driven generator and a 2½ kilowatt Cutting and Washington wireless set is provided.

On her maiden voyage from New York to Tampico the *Toteco* averaged a speed of 9.3 knots, which is about a knot faster than anticipated in view of the fact that the vessel was fitted with a towboat type wheel.



International Petroleum Company's Mexican Sea Loading Station Tender Toteco

Motorship Teneriffa: Length, Between Perpendiculars, 425 Feet 5½ Inches; Beam, Molded, 55 Feet; Depth, 38 Feet 6 Inches; Draft, Loaded, 29 Feet ¾ Inch; Displacement, Loaded, 15,025 Tons; Deadweight Capacity, 10,875 Tons; Indicated Horsepower, 3,100; Speed, Designed, 11¼ Knots

Norwegian Motorship Teneriffa

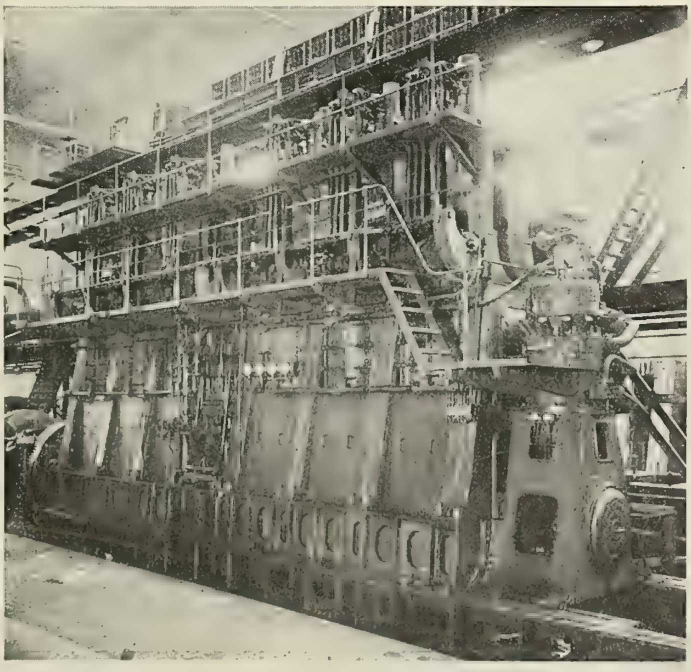
Twin Screw Cargo Ship of 11,000 Tons Deadweight Built by Burmeister and Wain

By Our Special London Correspondent

THE motorship *Teneriffa,* the first of three oil engined vessels being built by Burmeister and Wain for Wilhelm Wilhelmsen, the well known Christiania shipowner, ran her trials in May. She is a standard vessel similar to many which Burmeister and Wain has built for other owners, having a deadweight capacity of about 11,000 tons. The length is 425 feet, the beam 57 feet and the speed is 11¼ knots on a fuel consumption of 10 tons daily.

The *Teneriffa* is a pure cargo vessel, with accommodation for about a dozen passengers. The machinery equipment is of the well known Burmeister and Wain standard design comprising two sets of six cylinder four cycle engines developing 1,550 indicated horsepower at 120 revolutions per minute and having six cylinders 630 millimeters bore and 960 millimeters stroke.

The control of the engine is, as usual, effected by a small reversing and two starting throttle levers. On actuating the former a servo motor is brought into operation which lifts the push rods off the camshafts, moving the camshafts fore and aft and bringing the astern cams below the push rods; afterwards the latter are brought into contact with their cams. The engine is then in a position to run in the astern direction and by moving both of the starting and throttle levers forward, starting air is admitted to all six cylinders. A further movement of these two levers causes the fuel pumps to be brought into operation and the starting air is cut off.



One of the 1,550 Indicated Horsepower Diesel Engines Installed in the Teneriffa

The engines will run down to a minimum speed of about 60 revolutions per minute which is sufficient for all maneuvering purposes. The air injection compressor of the three stage type is driven off the forward end of the main crank shaft supplying air at a pressure of 68 atmospheres.

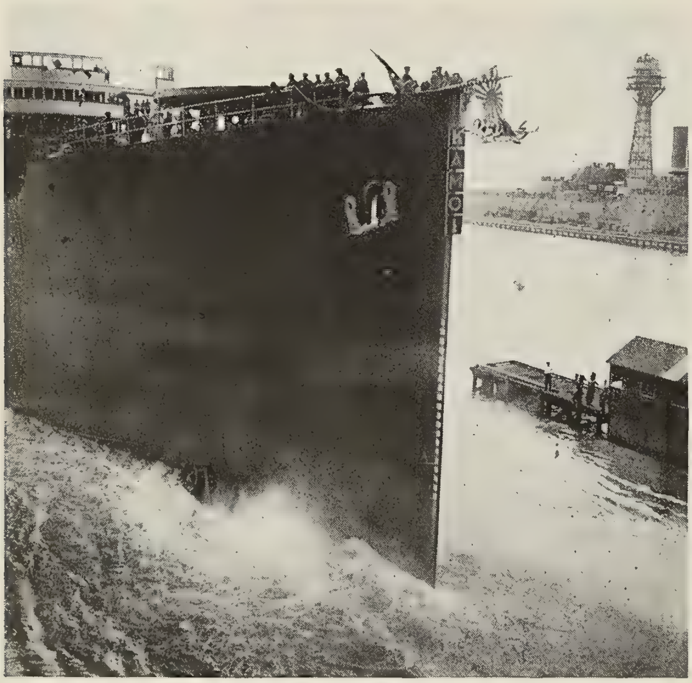
Fuel is carried in the double bottom, the total capacity being 1,800 tons while 15 tons of lubricating oil are allowed for.

The auxiliary plant is electrically operated and three Diesel driven dynamos of 90 horsepower running at 300 revolutions per minute are installed in the engine room for this purpose. They supply power to the three lubricating pumps, the piston and circulating water pumps and the other auxiliaries in the engine room. In addition, the electrical plant comprises 12 three-ton cargo winches, the windlass and an electric hydraulic steering gear. There is a single electrically driven air compressor installed in the engine room in addition to a small emergency set for the same purpose, which is steam driven and is of course only brought into operation in case of complete loss of air on the ship. A donkey boiler is fitted which supplies steam to this engine, in addition to generating steam for heating the cabins.

During the official trials of the *Teneriffa,* which were held over a measured mile course on May 3, the vessel displaced 4,802 tons on an average draft of 10 feet 4¾ inches and developed an average of 3,383.8 indicated horsepower at 138.4 revolutions per minute, giving the vessel an average speed of 12.29 knots. During the consumption test, the main engines developed 3,254.49 indicated horsepower at 134.6 revolutions per minute with a fuel consumption of 0.2973 pound per indicated horsepower per hour, including the consumption of the auxiliary engines producing the necessary current for the auxiliary machinery, steering engine and electric lights. The fuel oil used had a calorific value of 18,450 British thermal units.

Japanese Fuel Ship Kamoi Launched by New York Shipbuilding Corporation

THE twin screw, fuel supply ship *Kamoi,* launched on June 8 at the yards of the New York Shipbuilding Corporation, Camden, N. J., and christened by Madam Saburi, wife of the Charge d' Affaires of the Japanese Embassy, Washington, D. C., and daughter of the famous Marquis Komura, is the first electrically propelled ship of the Imperial Japanese Navy. On a length of about 500 feet and a designed draft of 28 feet the vessel has a displacement of 20,000 tons and a deadweight carrying capacity of about 13,000 tons. She is designed to carry 10,000 tons of oil; provision also being made for alternately carrying about 2,000 tons of bunker coal.

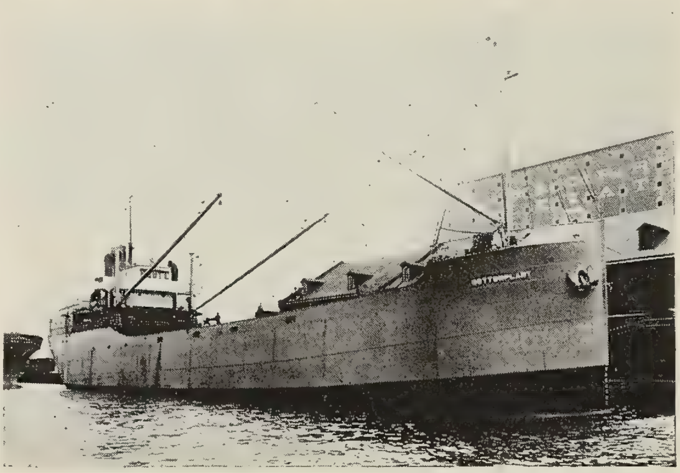


Launching of the Kamoi

The vessel is electrically propelled and is expected to achieve a speed of 15 knots with 8,000 shaft horsepower. The boilers are of special design and are coal fired; provision being made, however, for auxiliary oil firing.

Great Lakes Type Freighter Converted to Oil Burner

THE S. S. *Cotton Plant,* a Great Lakes type freighter owned by the Pacific Lumber Company of San Francisco, Cal., has recently been converted from a coal to an oil burner for use in the lumber trade on the Pacific Coast. Installation of the oil burning equipment, consisting of a complete Bethlehem-Dahl mechanical system, was carried out by the Baltimore Dry Docks Plant, Baltimore, Md., of the Bethlehem Shipbuilding Corporation, Ltd.



S. S. Cotton Plant Converted to Oil Burner

The *Cotton Plant* was built for the United States Shipping Board in 1919 by the Great Lakes Engineering Company at Ecorse, Mich., and was recently purchased by the Pacific company. The following are her principal dimensions:

Length	253 feet 4 inches
Beam	43 feet 7 inches
Depth	24 feet 5 inches
Capacity	4140 deadweight tons
Speed	10 knots
Boilers	2 Scotch, 13 feet 6 inches by 11 feet
Engine	1 three-cylinder, triple-expansion

New Airplane Compass.—A satisfactory type of airplane compass has been invented by Doctors Paul R. Heyl and Lyman J. Briggs of the Bureau of Standards, of the Department of Commerce. Flying tests with this instrument have been made, and the air service is now engaged in putting a number of models into service. The instrument weighs only 13 pounds, while the weight limit set by the air service was 25 pounds.

The new compass depends for its action not on a magnetic needle, but upon a revolving coiled wire. This principle is by no means new, but it has remained for the Bureau of Standards to apply it in such a way as to make the device practically operative under the very severe conditions prevailing in actual flight or airplane stunts.

The problem of perfecting a satisfactory aircraft compass was given the Bureau of Standards about a year ago. At the end of the war no completely satisfactory compass had been devised. Its importance to aviation is apparent when it is remembered that no airplane compass heretofore perfected has been able to keep up with the evolutions of a plane in all kinds of service.

Diesel Electric Schooner Yacht Alcyone

Three-Masted, 168-Foot Yacht Equipped with Winton-Diesel Westinghouse Electric Auxiliary Propelling Machinery

By H. C. Coleman*

WHEN Henry W. Putnam, of New York City, owner of the three-masted auxiliary schooner yacht *Alcyone,* found it necessary to replace the old reciprocating engine drive on his boat, he was so impressed with the many advantages of the Diesel-electric system of propulsion that he gave orders for the removal of the engines, boilers and auxiliaries and for the installation of two Diesel engines with electrical transmission of power to the propeller. As a result of his decision to adopt this most modern development in marine propulsive equipment, there passed down the lower bay in New York Harbor recently, on her sea trial, one of the finest equipped and easiest handled little vessels we have ever seen.

Fig. 1.—Auxiliary Schooner Yacht Alcyone

The *Alcyone* (Fig 1) is registered at 420 gross (262 net) tons and is 168 feet long overall, with a beam of 30 feet and draft of 15 feet. She has been completely refitted and overhauled. A large deck house had been added to the quarters amidships.

The propelling plant of the yacht consists of two six cylinder, Winton Diesel engines, direct connected to Westinghouse direct current generators, which supply a double unit motor, direct connected to the propeller shaft. Each engine is rated at 225 horsepower at 250 revolutions per minute. Each engine drives a 140 kilowatt, 125 volt, shunt wound, direct current generator and a 15 kilowatt, 125 volt compound wound exciter. The exciters are operated at 900 revolutions per minute, being driven by Morse chains from the main generator shafts.

The engine and generator, together with the generator bearing, are mounted on a rigid cast steel semi-bedplate, as shown in Fig. 2, making the unit convenient to handle and secure in the boat. The sets are placed abreast of each other in the vessel, with the exciters mounted outboard and supported on structural steel work, securely fastened to the ship frames. Fig. 3 shows the engine room looking forward from the motor room door.

The generator bearings are of the standard sleeve type with oil ring lubrication. Provision is also made for forced feed lubrication from the engine oiling system, as an auxiliary method of oiling the bearings.

The propelling motor is of the double unit type, consisting of two field structures and two armatures mounted on a common shaft, supported by two pedestal bearings. It is rated at 350 horsepower, 250 volts, 175 revolutions per

*Marine section, general engineering department, Westinghouse Electric & Manufacturing Company.

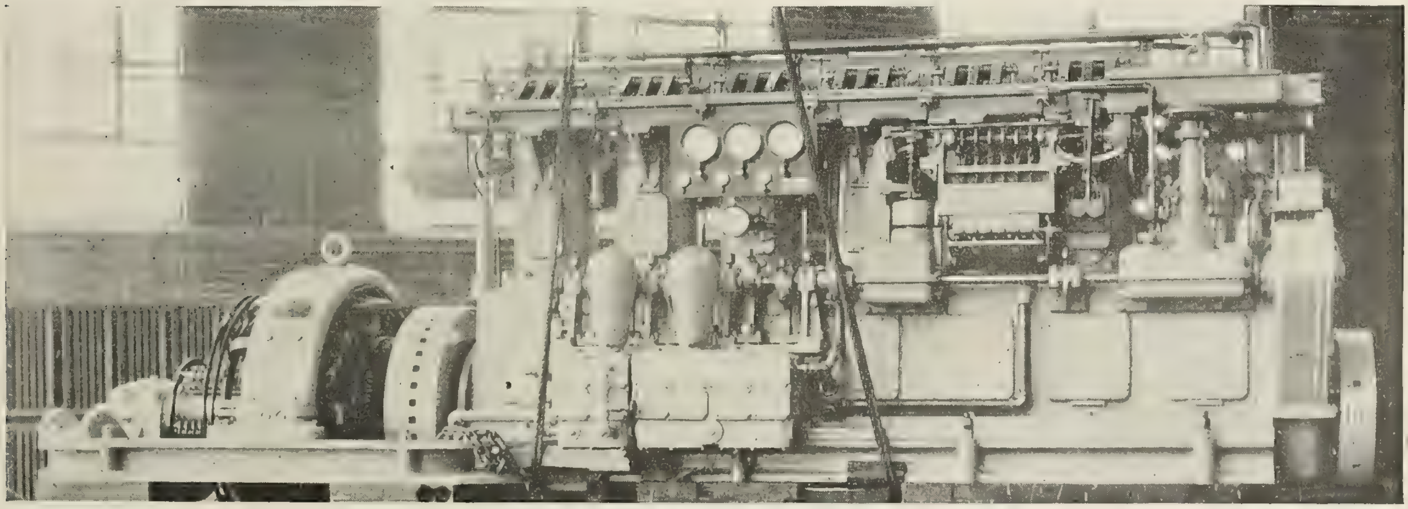


Fig. 2.—One of the Two 225 Horsepower Winton Diesel Engines Connected to a 140 Kilowatt Westinghouse Generator

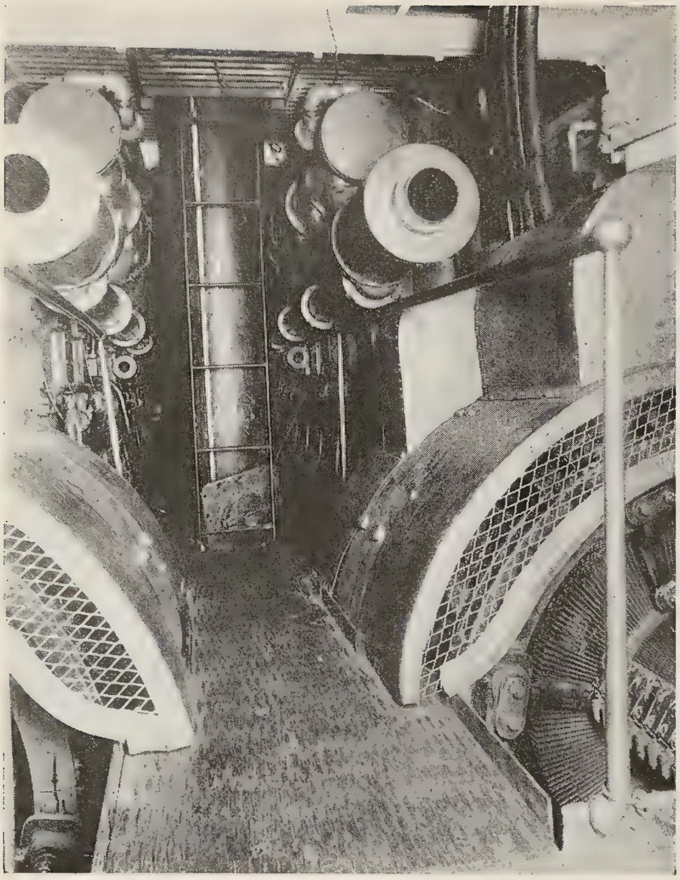

Fig. 3.—View in Engine Room, Looking Forward From Motor Room Door

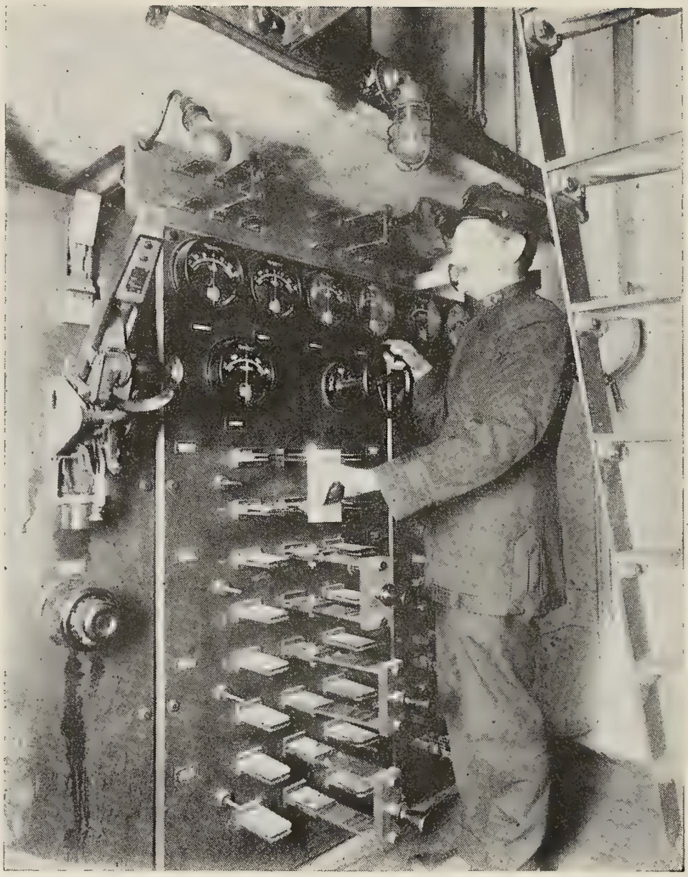

Fig. 4.—The Control Board for Propelling Equipment, Showing Chief Engineer Operating the "Master Controller"

minute, and is of the shunt wound, self-ventilated type. The bearings are duplicates of those used on the main generators. They are fitted with an auxiliary gravity feed oiling system, consisting of a small reversible geared oil pump, direct connected to the front end of the motor shaft and mounted on the bearing pedestal, and an oil reservoir to which the pump lifts the oil from the bearing overflow connections. A by-pass with pressure gage and valve for regulating the pressure is provided in the piping system.

The motor is located well aft where the lines of the vessel are very fine, necessitating the use of a double unit machine. The frame supporting feet are located near the horizontal centerline of the motor and are carried on steel beams secured to the ship's framing. The bearing pedestals are supported on yokes, the ends of which are mounted on the side beams which carry the motor field frames. The shaft is flanged and is bolted directly to the propeller thrust shaft.

The motor room is ventilated by a motor driven blower located in the engine room.

Control

The most interesting feature of the installation is the control, which must provide for ease of operation, responsiveness to the action of the operator and absolute reliability in the handling of the ship under all conditions. It must be simple and still provide for the maximum of flexibility of operation. It must protect the machinery against dangerous overloads, and still prevent damage to the ship, due to loss of power in an emergency. All of these requirements are admirably met by the control equipment which has been installed on the *Alcyone.*

Fig. 4 shows the complete control board for the propelling equipment, as installed on this boat. It is mounted fore and aft on the starboard side of the flat above the after end of the engine room.

The Ward Leonard scheme of control is used, whereby the starting, reversing and complete speed control of the motor is effected by adjusting the excitation of the separately excited, main generators. This makes the actual operating, or "master controller" part, so to speak, very small, simple and easy to handle, since only the generator field current has to

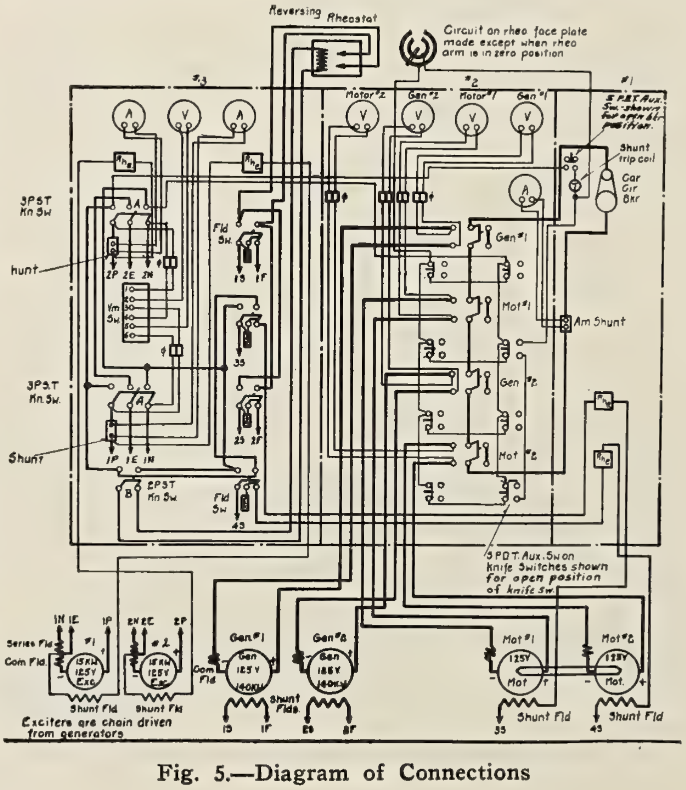

Fig. 5.—Diagram of Connections

be handled. This current is only about 1½ percent of that in the main armature circuits.

Master Controller

The "master controller" consists of a reversing rheostat located behind the switchboard and operated through chain and sprockets, from the main control hand wheel on the face of the panel, shown in Fig. 4. The same panel carries a double pole, double throw, knife switch, for each main generator and each motor armature. As will be seen from the diagram of connections, Fig. 5, the two generators may be connected in series with the two motor armatures also connected in series, by closing the switches to the left side. This is the running condition for full power operation. By closing the proper switch to the right side, either generator or either motor armature may be cut out of the series circuit, allowing for operation on the remaining units, connected in series. These switches are electrically interlocked with the circuit breaker so that any movement of them with the reversing rheostat in any position, except the "off" position, will trip the breaker; also the breaker will not remain closed, if the motor switches are both in the short-circuit position.

Convenient to the main control hand wheel is an ammeter, showing the operator the load on the motor, either ahead or astern, the instrument dial being marked accordingly. Above, on the same panel are two generator voltmeters and two motor voltmeters. All instruments have black dials with white scales and pointers, making them very easy to read in such a location.

Circuit Breaker

On the adjacent panel is the carbon circuit breaker which is set to open only on extreme overloads. It is not possible in ordinary maneuvering to obtain loads sufficient to trip the breaker and jeopardize the safety of the ship; as for instance in docking. This panel also carries two motor rheostats with concentric handles. With these, the fields can be adjusted so that the two armatures divide the load equally, as shown by equal readings on the two motor voltmeters. Then the two rheostat handles are clutched together, and operated as one thereafter.

Rheostats and Switches

The third panel carries the instruments, rheostats and switches for the two exciters, which may be operated either singly or in parallel on the excitation bus; also the motor and generator field switches and the reversing rheostat disconnecting switch. Each exciter is capable of supplying excitation to the complete propelling plant, thus leaving the other unit as a spare or as a source of power for auxiliaries. Above the main panel are two double throw switches, by means of which either main generator or either exciter may be connected to the auxiliary power bus. All switches and meters are plainly marked with suitable name plates, with white letters on black background.

After the main knife switches, field and exciter switches and circuit breaker have been closed, the operator has complete control of the maneuvering of the ship in the one main control hand wheel. The motor responds immediately to the movements of this hand wheel, and the complete operation of going from "full ahead" to "full astern" consists only in moving this hand wheel through 180 degrees. Since no circuits are opened, burning and consequent wearing of contacts, always present to a greater or less degree in other forms of control, are eliminated, which makes for reliability and low maintenance cost.

The reversing rheostat provides for 30 economical running speeds, equally apportioned between zero and the maximum, either ahead or astern. Also operation can be had from either main generator and both units of the motor at full power on the generator, in case one generating set is out of commission, or for a cruising speed. In this case, the motor field strength is reduced by the double rheostat, causing the motor to speed up, until full power is absorbed from the generator. The value of this arrangement for cruising is seen from the fact that the vessel will make a speed of 8.5 knots and has a cruising radius of 6,450 miles on one engine, while she makes a speed of 10.5 knots and has a cruising radius of 3,915 miles on both engines.

It is interesting to note that the same propeller and shafting as were used on the old steam engine drive were retained for the electric drive. Also very few alterations had to be made to accommodate the motor and generating sets. This is an example of how easily the steam driven ships may be converted into much more economical Diesel electric driven boats.

Trials

The equipment on the *Alcyone* operated to the satisfaction of all concerned on her trials. During her sea trials, a four hour full power run was made. The average propeller speed for this run was 160 revolutions per minute and the average boat speed 10.5 knots. The temperature of the machines at the end of the day's run, which included maneuvering in addition to the full power run, showed that considerable reserve capacity was available in the apparatus, if needed for emergency use. During the maneuvering trials it was demonstrated that the yacht could be stopped from full speed in less than double her length.

The *Alcyone* is the third schooner yacht to be equipped with this type of drive. The first two were the *Guinevere*, equipped with a 550-shaft horsepower drive, and the *Elfay* with a 90-shaft horsepower drive of the same type.

The engines of the *Alcyone* were made by the Winton Engine Works, Cleveland, O., while the electrical propelling equipment was built by the Westinghouse Electric & Manufacturing Company. The installation was made at the Tebo Yacht Basin of the Todd Shipbuilding and Dry Dock Corporation, under the supervision of Tams and King, naval architects, of New York.

The Reconstruction Hospital

ONE of the outcomes of the Great War has been an intelligent study of both the mechanical and therapeutic means of bringing maimed men back to physical health and usefulness. In this connection the ground has just been broken at 100th street and Central Park West, New York City, for a Reconstruction Hospital dedicated to the rehabilitation of men injured in the industries.

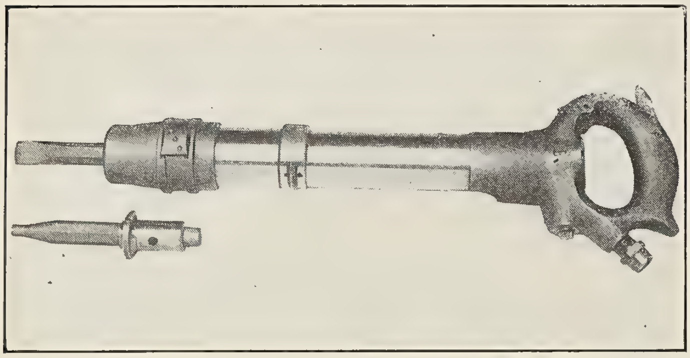
As seafaring men and shipyard workers are engaged in hazardous occupations where a physical disability disqualifies them from employment at their regular work, it is to the advantage of society as well as to the men who are crippled, to have a hospital where such restoration is made possible.

Seafaring men are particularly helpless when injured, as they often lack either the friends to help them or the knowledge of where to go to get aid. In the old days they were often seen limping around the waterfront, a burden to themselves and useless to the trade in which they had been trained. An institution devoted to the physical and mental restoration of men in such unfortunate circumstances can do a great deal of good.

Shipping Board Contract.—The Emergency Fleet Corporation has just entered into a contract with the Texas Company for the movement of between 500,000 and 1,000,000 cases of oil to East and South African ports. This movement will be based on monthly shipments and extend over a period of a year under the managing agency of the Mallory Transport Lines, Inc.

Pneumatic Tool for Removing Rivets

A pneumatic tool for removing rivets, known as the Thor No. 90-S rivet buster, has just been placed on the market by the Independent Pneumatic Tool Company, Chicago. This is a substantial tool, as shown in the illustration, being similar in design to the Thor riveting hammer. It can be operated by one man instead of three and used in close quarters. The tool is well adapted for cutting off and backing out rivets of all sizes.



Easily-Operated Thor Pneumatic Rivet Buster

The operation of this tool by one man instead of three results in a considerable labor saving. Rivets can also be cut in more difficult corners and there is less possibility of damaging the steel plates.

On account of the blows being rapid but not so severe the plates do not buckle at rivet holes, thus wasting expensive material as is often the case with the old style heavy three man buster. The Thor machine is designed to cut the rivet off smoothly at the surface of the sheet without disfiguring or spoiling the material.

The chisels and backing out punches are provided with individual safety retainers and can be quickly changed in the hammer from cutting off to backing out without disassembling the small retainer from the shank.

Auxiliary Steam Yacht Completes Cruise Around the World

THE former flagship *Aloha* of the New York Yacht Club, owned by Commodore Arthur Curtiss James of New York, has just completed a cruise around the world, arriving at Newport, R. I., on June 1. She began the long cruise from New York on September 15 last and followed the route through the Panama Canal to Honolulu, China, Japan, Philippine Islands, India, Java and Ceylon, and passed through the Suez Canal to Marseilles, France.

The last leg of the cruise from Marseilles was made over the northern route, a distance of 3,900 miles, in 22 days, which was considered a very creditable record in view of the bad weather encountered on the way across. The yacht behaved remarkably well on the entire trip and when she was docked at Newport showed practically no effects of her long voyage.

During the war the *Aloha* served in the Navy as the flagship of Rear-Admiral Cameron McR. Winslow. She was built for Commodore James in 1910 at the Fore River Plant, Quincy, Mass., of the Bethlehem Shipbuilding Corporation, Ltd., and is equipped with two watertube boilers and one triple expansion steam engine, with cylinders 12 inches, 19 inches and 30 inches diameter by 24 inches stroke for auxiliary power. The yacht is 218 feet 4 inches in length overall and 35 feet 5½ inches beam, molded.

Webb Institute Celebrates Annual Commencement

Distinguished Speakers Address Graduates—Advice Applies Equally Well to Those Who Are Learning by Experience

THE WEBB INSTITUTE, which is devoted exclusively to naval architecture and marine engineering, held its twenty-sixth annual commencement on June 10. In the absence of Commander Stevenson Taylor, president of the institution, who was in Europe at the time, Captain W. M. McFarland, vice president, acted as master of ceremonies.

Captain McFarland said it was a matter of great regret to him that Commander Taylor could not be there for he considered that the commander's work at the institute was of equal beneficence to that of Mr. William Henry Webb, its founder. Captain McFarland then read a cablegram from Commander Taylor which follows:

"I regret my absence from commencement today, the second time only since the first graduating exercises in 1897. My heart is with you all, trustees, officials, guests and students, particularly with those who now commence assuming responsibilities to which doubtless they look forward with pleasure. God speed them and bless all."
"STEVENSON TAYLOR."

Stevenson Taylor

Walter M. McFarland

THE CHAFFEY MEMORIAL PRIZE

Announcement was next made that the alumni had raised and presented to the Institute over $1,000.00, the interest on which was to be awarded annually to the student showing the highest degree of mental, moral and physical fitness. The prize this year was given to J. Byron Blood, who later read the valedictory address.

Captain McFarland concluded his remarks with the expression that it is a source of great satisfaction that a sound engineering education is a splendid foundation for a success in many fields and even though the present outlook in naval architecture and marine engineering is anything but bright and some of the graduates would probably have to enter other lines, he was confident that the passage of pending shipping legislation would encourage American citizens to build and operate vessels under the American flag.

A MAN TRAVELS BY HIS MIND

Commander Richard D. Gatewood, Director of the Division of Construction and Repair, United States Shipping Board, said in part:

"You gentlemen of the graduating class from this day forth start out to sea. Some of you actually will go out to sea. All of you, however, will start out upon that other sea of commercial life in which there are so many rocks, so many narrow shoal places, so many currents and so very few charts.

"We live by our visions, and the ambitious, the venturesome, the progressive among us, using the light of imagination and guided by reason and judgment, discern dim objects on the horizon of the sea of life toward which we feel impelled to move. But *then,* when we satisfy those desires, when we find the something greatly coveted, the horizon is still as far away as ever, and other shapes are always looming there calling our restless *minds.*

"It is for this that teachers have been training your *minds* these many careful years. They haven't trained your five physical senses, they've trained your *mind.* Surely you know that you cannot perceive absolute truth through the five senses. If men had tried to do that, the earth would still be flat, the sun would revolve around the earth and sink each night into the sea, the moon would be a silver disk in the sky a few inches in diameter. The greatest things of all, love and truth and duty and loyalty and courage, we can't know by our senses. We know them by our *mind.* The truth of the multiplication table is in no way dependent on our senses, is it?

"From today you will not travel any longer together, but let me ask you to be good travelers, to study the men you meet along the way and know that they must not be judged by their weaknesses, but rather by their power to lift their heads above others in time of stress and peril. Cultivate high ideals and hold fast to them whatever comes. Hold fast to the spirit of this Institute, hold fast to the spirit of the profession, the love of duty that is stronger than the love of life.

"Will you cultivate the art of traveling, the spirit of patient observation, the spirit of progress? I ask you because your careers will be watched with great interest. Word will come back here where you start. Will it be a good voyage you are about to make? *A man travels by his mind.*"

STICK-TO-IT-IVENESS

Mr. Alfred W. Kiddle, president of the Engineers' Club, stated that "the great thing in life is continuity of purpose founded, of course, on good conscience and directed by lofty ambition. Therefore, whatever particular field of endeavor within the great engineering profession, or indeed, in any of the other learned professions or in business, perhaps, that you may select in which to devote your faculties and your

labor, I enjoin upon you to determine for yourself as soon as may be possible a definite purpose or aim and rigidly adhere thereto, for work without an object leads to no achievement, and life without an aim is like a ship at sea without a port or destination.

Webb Appreciative Fund

Mr. Joseph Husson, president of Webb Alumni Association, spoke of a "quarter of a million dollar fund" that had been subscribed by the graduates in appreciation of a four-year education in naval architecture and marine engineering together with meals and room during the school term of those four years, absolutely without cost. Competitive examinations are held each year in September. The Webb Institute was endowed in 1891 and opened in 1895 by William H. Webb, one of New York's most famous shipbuilders in the days when American clippers ruled the seas.

Dolphin, Largest Diesel Yacht, Delivered to Owner

The Diesel cruising yacht *Dolphin,* built by the Newport News Shipbuilding & Dry Dock Company from designs of Cox & Stevens, New York naval architects, for Mortimer L. Schiff, was delivered to her owner on Saturday, June 3, having been only three months under construction. The *Dolphin* is claimed to be the largest Diesel motor yacht built in this country, being 180 feet in length, 24 feet beam, 14 feet depth of hold and equipped with two 500 horsepower Winton Diesel engines.

Maiden Voyage

The yacht left the builders' yard on Saturday morning, June 3 and arrived in New York harbor at two o'clock Sunday morning, her average speed from the capes to the lightship being 14½ knots without forcing the engines.

The *Dolphin* will be a notable addition to the yachting fleet as she is a sturdy craft with excellent sea-going qualities and accommodations that are most unusual both in the size and attractiveness of the various large rooms on deck as well as the living quarters for the owner and guests.

(Photograph by M. Rosenfeld, N. Y.)

Diesel-Engined Cruising Yacht Dolphin

Shipping Board Sells Diesel Engines.—The Material Sales Division of the United States Shipping Board Emergency Fleet Corporation has just consummated the sale of 2 McIntosh & Seymour 900 horsepower Diesel engines to the Munson Steamship Lines. It also has for sale the following Diesel engines: 2 Bolinder 320 horsepower; 1 McIntosh & Seymour 750 horsepower; 4 McIntosh & Seymour 750 horsepower; 8 Scandia Pacific Oil Engine Company 825 horsepower; 2 Scandia Pacific Oil Engine Company 825 horsepower; 2 McIntosh & Seymour 900 horsepower—1 right hand and 1 left hand.

Steamship Cynthiana Recently Built by Irvine's Shipbuilding and Dry Docks Company, Ltd., Middletown Shipyard, West Hartlepool, for Furness, Withy and Company, Liverpool

The vessel is of the shelter deck type, built to Lloyds' highest class, the dimensions being 435 feet 6 inches in length by 55 feet beam extreme by 30 feet 6 inches depth molded. She has three complete decks and a top-gallant forecastle, six hatches, grain divisions throughout, and water ballast in cellular double bottom, fore and after peaks and two large deep tanks, placed respectively forward of the boiler room and aft of the engine room. Propulsion is by a triple expansion engine with cylinders 29, 49 and 80 inches in diameter by 54 inches stroke supplied by Richardsons, Westgarth & Company, Ltd., Hartlepool. Steam is supplied at 180 pounds per square inch by four Scotch boilers working under Howden's forced draft and arranged for burning either coal or oil. On trial the vessel made a speed of 12½ knots.

Adjustments of the Compass

Causes of Deviation of the Compass and Methods of Compensation

By C. H. Peabody, Dr. Eng.

THE magnetic compass points more or less to the north; the angle which the needle makes with the true north, that is, the geographic north, is known as the variation. In the northern states and the North Atlantic the variation is to the east; it may amount to fifteen degrees. Charts showing the magnetic variation are issued by the United States Coast Survey, variations to the east being marked plus and those to the west minus. The navigator of a wooden ship, with no iron near the compass, needs only to allow for the variation in order to steer a true course. Thus, if the variation is 10 degrees east and if the true course is 55 degrees northeast, the navigator will give the steersman the magnetic course as N. 45 degrees E.; that is, the magnetic course will be northeast. This comes from the fact that the compass card has 32 points each equal to 11 1/4 degrees, the ship's course is then north four points east, which comes out northeast as given. But compass cards are now divided into degrees as well as points and the courses are commonly given in degrees. The latest naval practice is to divide the compass card into 360 degrees numbered from north right around by the east and south. Thus, S. 45 W. becomes 225 degrees.

In some localities the variation may be very large; for example, in northern Canada near Baffin's Bay the compass becomes very unreliable which adds to the difficulties of Arctic navigation.

Iron Must Be Kept Away from the Compass

It is very important that iron should be kept away from the compass on a wooden ship; if for any reason it is impossible to do this, then some adjustment of the compass may be necessary. Such adjustment is commonly simple, but being unusual may be perplexing even to a compass adjuster; reference to this matter will be made later.

But ships, and especially steamships, are likely to be built of steel which affects the compass variously and intelligent adjustment becomes necessary.

For steel ships the same precept holds, that steel and iron must be kept from the immediate neighborhood of the compass, so far as possible. It is well that the wheelhouse should be built of wood and no loose iron and, in particular, no magnets should be kept in the wheelhouse. The shafting leading to the steering engine (or to the rudder) should be made of composition. Even the quartermaster must be considered and not allowed to carry a large clasp knife or other iron or steel.

Magnetism of the Ship

All the steel delivered at the building slip is likely to be magnetic in some degree, and the processes of working the steel into the ship, especially hammering, develops magnetism, so that the ship in a sense becomes one huge magnet. But again, we must keep in mind that steel or iron near the compass has the greater influence; a steel cargo boom near a compass may have more effect than the smokestack at a distance; such a boom must be stowed in its supports when compasses are adjusted.

The navigating compass is often on deck or on the bridge in such place as is at once convenient for taking observations and as little influenced by magnetism as possible. On a steel ship no place entirely free from magnetism can be found, but there is always a choice.

The magnetism we are now considering is called "permanent magnetism," because it is not changed by moving the ship around, nor by sailing to a distant port. It is liable to decrease more or less slowly but that matter will be treated by itself.

The whole effect of permanent magnetism may be likened to that of two magnets at the level of the compass; one magnet may be taken as fore-and-aft; that is, either forward or abaft of the compass; the other magnet may be taken as athwartship; that is, either to port or starboard. The permanent magnetism of the ship may consequently be compensated by two magnets that can be adjusted near the compass.

Compensation of Ship's Magnetism

An evident way of compensation is by the use of large bar magnets which are soldered up in copper cases to avoid corrosion. Now the north end of the compass needle is that which points to the north; and any magnet may have its similar end marked *N* or north. To test a magnet bring one end near the compass; its north end repels the north end of the compass needle. Sometimes the magnet or its case is painted red at the north end and blue at the south end. We have for a reminder that *r* is found in "north" and in "red," while *u* is found in "south" and in "blue."

Fig. 1

In all cases, powerful magnets or other magnetic material should be brought near magnets only by intention and deliberately; "near" in this case means near enough to give intended effect and not "nearer."

Suppose that the ship has been brought on a correct magnetic north and south course, as shown by Fig. 1; and that the compass needle makes an angle with that course, which angle is known as the deviation of the compass. A bar magnet may be laid down athwartship as shown with the north end to the starboard; it will tend to correct the deviation and it can be moved toward the compass until the deviation disappears. This operation will correct the athwartship magnetism of the ship.

The ship may then be brought to a correct east and west magnetic course, as shown by Fig. 2. A fore-and-aft magnet

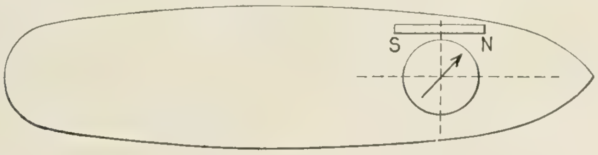

Fig. 2

may be laid down and brought up toward the compass until it corrects the fore-and-aft magnetism of the ship.

Semi-Circular Deviations

The deviations just discussed are known as semi-circular deviations. To explain this term let us admit that the fore-

and-aft magnetism could be represented by a single long magnet forward of the compass with its south end up and the north end at a long distance below. This south end will act as a single point of attraction to the north end of the needle, as shown in Fig. 3, and it will draw the needle toward the east, producing a deviation. If the action begins with the magnet *S* in the north and south line, no deviation will be produced. As the magnet is carried around, the deviation will increase until the magnet is nearly but not quite east of the compass. Going on, the deviation will decrease until it disappears when the magnet is south of the compass. A semi-circular motion thus produces a complete cycle of deviation; the other half circular motion from south to north will produce a similar cycle of deviation to the west. A similar action takes place when a ship swings all the way around from north to east, to south and then to west and north.

Fig. 3

Bar magnets may be placed forward or aft of the compass or on either side; or both forward and aft or on both sides. Some binnacles are four sided with facilities for fixing as many bars as may be needed. The Ritchie compasses have fore-and-aft and transverse trays in the binnacle, into which magnets can be laid in the proper number; the trays can be raised or lowered to complete the adjustment. The Kelvin compass has small bar magnets in the compass bowl, with screws for adjusting them. In any case the method is essentially the same. The methods all are tentative and any error can be at once detected and corrected.

Quadrantal Deviation

Thus far we have been dealing with permanent magnetism which changes slowly, if at all; but any soft iron bar which lies in a north and south direction immediately acquires magnetism, and it loses it progressively as it swings round toward the east or west. When such a bar lies in the line of the compass needle it has its maximum magnetism, but it does not deflect the needle. When it swings to the east, the south end draws the needle and gives it an easterly deflection which becomes a maximum at about 45 degrees; the magnetic effect

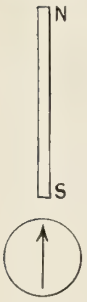

Fig. 4

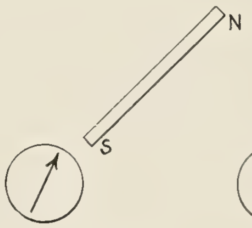

Fig. 5

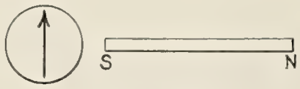

Fig. 6

decreases to zero as the bar swings so as to lie directly east as shown in Fig. 6; it then produces no deviation. As the bar swings toward the southeast the end near the compass acquires north magnetism which draws the south end of the needle to the east and produces a westerly deviation of the north end of the needle. Going on, the bar produces an easterly deviation when it lies southwest of the compass, and a westerly deviation when it lies northwest of the compass. This deviation, due to horizontal iron, is called quadrantal deviation.

Magnetic Effect of Ship's Deck Beams

If two bars are fastened to a frame at right angles with each other they will tend to counteract each other's effect. The more powerful bar will produce quadrantal deviation of its own kind but the deviation will be less. Any system of bars at right angles will in like manner give a resultant effect. The effect of any bar will depend on its length and size and on its proximity to the compass. The deck beams beneath a compass usually have the dominant effect. If a ship heads to the northeast, the deck beams will lie as shown in Fig. 8 and will produce an easterly resultant quadrantal deviation. The compensation is made by cast iron balls set in slots in a bar carried athwartship on the binnacle as indicated by Fig. 9. These balls have north magnetism at the north hemisphere and south magnetism at the south hemisphere however they may lie; this has been indicated by hatching the southern hemisphere; the actual balls are painted one color and give no such an indication. In Fig. 9 the balls have no resultant influence on the compass needle because individually they have equal and contrary influence. As the ship swings to the east the port ball, presenting its southern hemisphere to the compass, tends to draw the head of the needle to the west, and the starboard ball presents its north hemisphere and has a similar effect on the south end of the needle. This influence increases with the angle until it reaches a maximum when the ship heads to the northeast as indicated by Fig. 10. The balls thus have a quadrantal effect contrary to that of the beams as shown in Fig. 8.

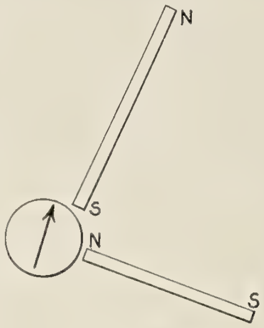

Fig. 7

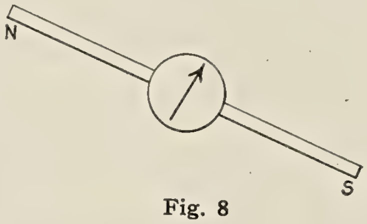

Fig. 8

Fig. 9

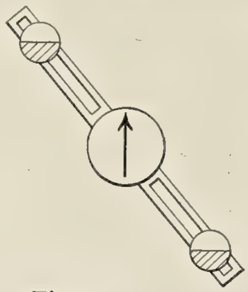

Fig. 10

Correcting Quadrantal Deviation

The quadrantal deviation is corrected after the semicircular deviation has been completed. The ship is put on a quarter bearing, for example it may head northeast; the compensating balls are put in the outer ends of the slots and are moved toward the compass until the quadrantal deviation disappears.

Actual Compensation of a Ship's Compass

To recapitulate: the ship is put on a principal bearing, such as north, as shown by Fig. 1, and a magnet is placed to correct the deviation then shown; the ship is turned through 90 degrees as shown by Fig. 2 on an easterly bearing and another magnet is placed to correct the deviation on that bearing; this completes the compensation for permanent magnetism. The ship is then put on a quarter bearing, as

shown by Fig. 10 and the quadrantal deviation shown is compensated by the balls.

In practice it is customary to test each compensation by reversing the course of the ship. For example, beginning on a northerly bearing and correcting the deviation as directed, the ship is immediately swung through a half circle and put on a southerly bearing; if there is no deviation on this southerly course, that step is complete. But, if there remains a small deviation on this southerly course, it must be reduced.

The first step is to see if the pin on which the needle is supported is eccentric; if so, it should be corrected; usually this point is looked after before the compensation is undertaken. If there is a deviation when the needle is known to be straight and when the compass card is concentric with the compass bowl, the custom is to correct half of it by moving the proper magnet. The ship is then turned around to a north bearing and an observation is made to see if there may be a deviation on that bearing. Perhaps there may be equal and contrary residual deviations on the opposite bearings; in such case the deviation must be recorded and allowed for in the navigation of the ship.

In like manner, if the ship is set and compensated on an easterly bearing, it is swung round to a westerly bearing and the residual deviation is divided between east and west bearings should there be any left. So also after the quadrantal deviation has been made on a quarter bearing, say N. E., the ship is swung round in succession to S. E., S. W. and N. W. to test the compensation; should there remain deviations on some or all of these points an attempt may be made to distribute the deviation; such a distribution is likely to be made only when the quadrantal deviation is very large.

The magnetic influence of horizontal soft iron is greatest near the equator and decreases toward the poles; but as the corrective influence of the balls varies in like manner an adjustment of quadrantal deviation at any latitude should be good for any other location.

It is customary to cast the arms for the quadrantal balls athwartship onto the binnacle for compasses of merchant ships. Warships sometimes have the arms given a little freedom so that they may be given a small angle with an athwartship line. This is to make it possible to refine the compensation and allow for the effect of diagonal members that may come near the compass. Such compensation is not conveniently made by the process here described and no further attention will be given to it.

Magnetic Effect of Vertical Soft Iron

Near the equator vertical soft iron has little or no magnetic influence, but as a ship goes north the vertical iron has greater and greater influence. In the northern hemisphere the lower end of a vertical bar has north magnetism; in the southern hemisphere this is reversed and the magnetism becomes south at the lower end. At any place the magnetism of a vertical bar remains constant and cannot readily be distinguished from permanent magnetism.

In our discussion of semi-circular deviation the effect of vertical iron has been ignored; in effect it has been allowed to go in with the effect of permanent magnetism. If a ship's service is in the middle latitudes of one hemisphere, this practice leads to no difficulty but, if the ship sails to the equator and yet more if she sails to another hemisphere, there should be a separate correction for vertical soft iron.

Compensating Magnetism of Vertical Iron

Commonly a compass is placed amidships and the structure of the ship is symmetrically arranged port and starboard, so that the effect of all the vertical iron is equivalent to that of a single bar on the ship's axis. The resultant effect of vertical iron on a compass in the wheel house is like that of a bar abaft the compass with its upper end on a level with the compass. A compensation can therefore be made by placing a proper bar directly forward of the compass; perhaps on the wall of the wheelhouse. This bar is known as Flinders' bar, named for Captain Flinders of the Royal Navy, who first detected and corrected deviation on certain wooden naval vessels which had iron pillars under the deck beams.

The convenient way of setting Flinders' bar is to wait till the ship comes into port at or near the magnetic meridian, which is located on magnetic charts. An investigation will show that the fore-and-aft compensation of the ship is overdone; that is, the ship on an east or west bearing will show a deviation contrary to that found on such a bearing when the ship was compensated. This deviation can be released by moving back the proper magnet from the compass. The number of degrees may be recorded for action after the ship returns to the home port or to a like latitude. After the return the ship will show a residual deviation on an east or west bearing. A proper soft iron vertical bar may be placed forward (or aft) of the compass to correct this residual deviation. A convenient way is to use a bundle of small rods and add or take away rods till the compensation is complete. When once this compensation has been made it will remain permanently.

It is not necessary to return to the home port to set Flinders' bar. At any port the compass may be taken ashore to some place free from local magnetism. The compass may be set so that the needle reads north; then a bar of soft iron may be brought near to a position such as it will conveniently occupy aboard, and the adjustment may be made by causing a deviation equal to that found aboard but in the contrary direction.

Influence of Iron Below the Compass

There now remains the consideration of the influence of iron or steel below the level of the compass. The resultant influence may be likened to that of a vertical magnet directly under the pin on which the needle is supported. When the ship is in quiet water such a bar cannot produce deviation; but when the ship rolls such a bar would swing from side to side and might give a trivial deviation. Should the time of swinging of the compass needle and its card be the same as the time of rolling of the ship, a troublesome oscillation of the card might be set up. To obviate this difficulty it is customary to provide a vertical permanent magnet under the compass that can be raised or lowered by a chain or other device. When the ship is rolling and the card is oscillating the magnet may be raised or lowered until the trouble disappears. Sometimes such a magnet may be found to be upside down, in which case it is reversed in order to make the compensation.

How to Prepare a Chart of Residual Deviations

After a ship's compasses have been compensated for semicircular and quadrantal deviations, with or without Flinders' bar and the vertical magnet just mentioned, it is customary to swing ship and prepare a chart of residual deviations.

The ship is brought in succession to regularly distributed bearings; there should be at least eight and preferably sixteen such bearings. If convenient, each of the 32 points of the compass may be used. The ship should be held two or three minutes on any bearing and then the true magnetic bearing should be determined and the reading of the compass taken; this is to allow for the lag of the compass, which is slow in coming to a fixed reading.

It is desirable to place the ship exactly on the desired true magnetic bearings and read the accompanying deviations; it is then easy to make a table of correct and compass bearings for each point of the compass so that the navigator may readily give compass bearings to the steersman, or may make proper correction to his observations. But, if the ship is brought near the proper bearings, a diagram may be made

from which a table can be interpolated; or the interpolation can be made arithmetically.

Usually, when compensation has been skilfully made the residual deviations are small and are easily allowed for. If the deviations are large and especially if they are irregular, the compensation should be repeated.

The construction and use of compass diagrams cannot conveniently be represented in this article; details may be sought in text-books.

Loss of Magnetism

Thus far we have considered that steel has permanent magnetism; but hard steel bars that are specially magnetized are liable to lose magnetism slowly even if provided with keepers. The steel worked into a ship is magnetized by hammering and other work done on it; the amount and kind of magnetism depend both on the amount of work and the direction in which the ship lies on the building slip. When possible the ship should lie in a contrary direction in the fitting slip; the work of fitting may then relieve some of the magnetism.

After the ship has gone into service the magnetism slowly decreases and the movements among waves at sea help along that effect. Ships are likely to have their compasses over adjusted after some time in service; the navigator should have this in mind to avoid inconvenience or even disaster. The magnetism so lost in service is known as sub-permanent magnetism.

Retentive Magnetism

If a ship lies in an approximate north and south position in port for several days, it is likely to acquire retentive magnetism amounting in some cases to two or three degrees. The captain of a certain ship coming out of Baltimore was accustomed to make an allowance for such retentive magnetism when coming out. Such an error might easily lead to grounding of the ship, if uncorrected. After some hours at sea retentive magnetism may entirely disappear. Retentive magnetism may be detected by taking the bearing of some convenient point on arrival at the dock and again just before sailing; any change is likely to be due to that cause.

It has been tacitly assumed that a ship may readily be placed on any magnetic bearing or any desired succession of bearings; the methods of accomplishing such a purpose have been purposely reserved for consideration to avoid confusing the obvious methods of compensation with the detail that may now be stated separately. There are several methods that may be employed as convenient.

Methods of Placing a Ship on Magnetic Bearings

At some docks magnetic bearings are marked by lines painted on adjacent buildings or by some other method. Such a device is more convenient for checking the condition of compasses than for making compensation.

If a ship at anchor swings entirely round with the tide, or if it can readily be made to swing round, opportunity can be taken to compensate the compasses or to note and record residual deviations. The inconvenience is that it takes a considerable time and that the swinging is irregular and may be too rapid at certain stages of the tide. The swinging may be controlled in part by springs on the cable.

A very convenient way of locating the various magnetic bearings, such as north, east, etc., is by taking bearings of some distant object such as a church steeple or any easily identified point, for which the true magnetic bearing may be known or can be obtained. Bearings can be taken by aid of a metallic ring that fits on the compass bowl and carries sight vanes. The sight vanes may have simple vertical slots or there may be one slot to peep through and a wire in a wide slot to aid in setting on the object in question. The object chosen must be far enough off so that the bearing will not be sensibly changed by the swinging of the ship; four or five miles is usually enough. If the bearing is unknown it may in some cases be found by sending a compass ashore and placing it so that it, the ship and the steeple (for example) are in one line. If the water is very quiet, it may be possible to get the bearing by aid of a compass in a small boat that can be placed in line with the ship and the steeple. Or, if the ship swings completely round and if bearings are taken at regular angular intervals, the true magnetic bearing can be found by taking the algebraic sum of all the apparent bearings.

Reciprocal Bearings

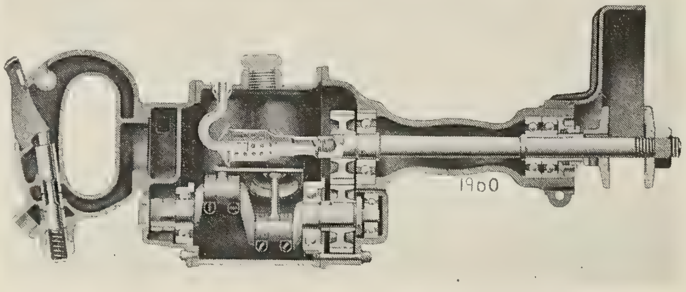
If it is convenient to send a compass ashore, the method of reciprocal bearings will be found rapid and easy. An observer aboard may take a bearing of the compass ashore and at the same time an observer at the shore compass may take a bearing of the compass on the ship. The shore compass should be free from local magnetic effect and will give a true bearing, which is opposite to the true bearing from the ship. Suppose the shore compass gives S. W. for the bearing of the ship compass; the true bearing of the shore compass will be N. E., or N. 45 degrees E.; suppose the observer aboard reads the bearing N. 50 degrees E., there then will be an easterly deviation of 5 degrees. It may be convenient to employ a tug to push the ship around; the tug, and especially its smokestaff, is liable to have magnetic effect and must be kept away from the compass under observation.

The most common way is to take the ship outside the harbor and steam it around onto desired bearings which are identified by taking observations on the sun. The observation most conveniently made is the altitude of the sun above the horizon by aid of a sextant; but by aid of prepared tables the azimuth of the sun can be taken or interpolated for the date and hour of the day. By the azimuth of the sun we mean its angular distance from the true or geographic north. Allowing for the magnetic variation the correct magnetic bearing can readily be identified, to which the ship may be brought by steaming around slowly. The idea is simple enough, but the application together with the use of tables may be best learned from a competent compass adjuster.

This article has purposely been written in a sketchy manner to avoid complexity and garrulity. Perhaps the reader may be able to make the compensation of a compass under simple conditions, perhaps it may aid in understanding compensations as made by an expert or perhaps it may lead to reading more ambitious presentations of this important and interesting matter.

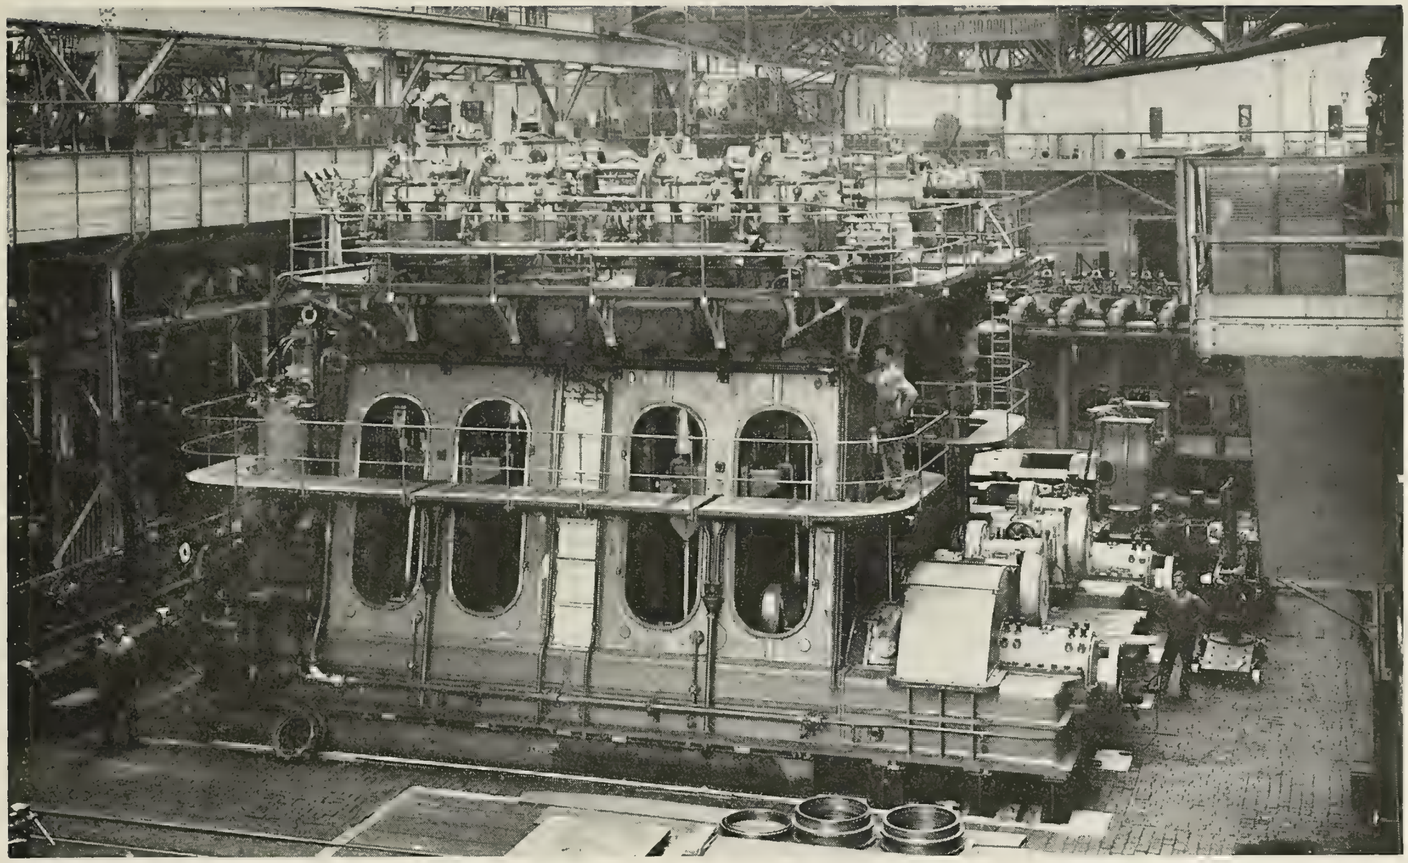
Oil Separator for Air Grinders

To permit air grinders to operate for long periods without replenishing the supply of lubricant, the Chicago Pneumatic Tool Company, Chicago, Illinois, has designed an oil separator which is applicable to "Little Giant" air grinders.



Oil Separator Applied to "Little Giant" Air Grinder

The oil separator consists of a hollow perforated cylindrical steel shell attached at one end to the grinder spindle while the other encircles and revolves around the vent tube.



Two 2,000 Brake Horsepower Sulzer Diesel Engines Erected in the Builders' Shop Preparatory to Installation in a 11,500-Ton Ship

Four Cylinder Two Cycle Sulzer Engine

Designed to Develop 2,000 Brake Horsepower at 100 Revolutions Per Minute—Turbo Scavenging Pumps Used

By Our Special London Correspondent

SHIPOWNERS, recognizing the advantages of motorships over steamers in present circumstances, are continually demanding of the builders that oil engines with higher powers should be developed. In addition there is a more general request for single screw ships which the average shipowner prefers, at any rate in moderate powers. Two main tendencies are therefore to be noted in European marine engine design: first, the production of motors with larger specific cylinder output, and secondly, the construction of slow running and consequently long stroke engines specially adapted for the slow speed of propeller rotation required in these vessels for maximum efficiency.

The greatest advance in the development of high powered engines has been made by Doxfords, whose four cylinder opposed piston engine with cylinders 580 millimeters bore and stroke of 1,160 millimeters now develops approximately 4,000 indicated horsepower or 1,000 indicated horsepower per cylinder. This is essentially a motor for installation in single screw ships running as it does at 77 revolutions per minute. Not to be outdone in this direction, the builders of four cycle engines are showing similar activity. Burmeister and Wain, which has already standardized a 3,200 indicated horsepower eight cylinder set running at 115 revolutions per minute for twin screw vessels, has now produced a long stroke design running at 85 revolutions per minute for single screw ships. An order has just been placed for the largest engine of this type yet constructed which will develop 3,200 indicated horsepower but at the lower speed of revolution.

New Sulzer Developments

Sulzer Bros. is also progressing along the same lines and has just completed the two largest sets of the single piston two stroke type which have yet been built for marine work. An illustration of these engines erected on the test bed is given and they will shortly be installed in the 11,500 ton motorship *Camramh* now under construction for a well known French shipowning firm, the Chargeurs Reunis.

A still larger set developing 3,500 brake horsepower in six cylinders is under construction, the diameter of the cylinders being about 36 inches and the stroke just under 48 inches. This latter engine is for installation in a large ship for the North German Lloyds and it is an indication of the ideas of the designers that plans for the construction of a 5,400 brake horsepower six cylinder Sulzer engine have been prepared. Two of these sets will shortly be laid down for installation in a large liner and it may be noted that the cylinder diameter is 900 millimeters and the stroke 1,550 millimeters—dimensions far in excess of any that have yet been used. It may be added that the overall length is 63 feet and the total height 25 feet.

Returning to the 2,000 brake horsepower engines, these are designed to run at 100 revolutions per minute developing

1,700 brake horsepower at 85 revolutions per minute. The cylinders have a bore and stroke of 680 millimeters and 1,200 millimeters, respectively, and it will be noted that the scavenging pumps are not direct coupled. Sulzers have in fact now standardized a system for all engines over about 1,000 brake horsepower by which the scavenging air is supplied from separate electrically driven turbo scavenging pumps. The object of this arrangement is to give additional shaft horsepower for given cylinder dimensions, while there is a slight reduction in weight and the designers consider that the method is generally more convenient. A small saving in overall length is also effected. A single three stage air compressor is driven at the forward end of the engine while at the same end are lubricating oil and circulating water pumps.

Cast Iron Framing Supports Cylinders

Although originally Sulzers adopted the steel column construction for supporting the cylinders and this has later been taken up by numerous Diesel engine builders, it is not used in the latest Sulzer motor. The cylinders are supported on heavy cast iron framing with large doors on the front which are removed in the illustration showing that easy access is available to the crank chamber.

The usual Sulzer system of port scavenging with a super charge of scavenging air admitted via a camshaft controlled valve through a series of auxiliary ports above the main scavenging ports is employed, which the makers claim enables them to maintain a high thermal efficiency; this seems to be borne out by the fact that on trials a fuel consumption of 0.398 pound per brake horsepower hour was attained.

Single Valve Cage in Cylinder Head

In each cylinder cover are arranged the fuel inlet, the starting and the relief valves. By a very neat design, these are all incorporated in one cage, so that only one hole has to be bored centrally in the cover, allowing a very strong construction to be adopted with ample and unrestricted cooling passages. A peculiarity of the engine is that the controls for maneuvering and reversing are located at the top of the cylinders although this is of course not essential. The builders, however, consider it advantageous since most of the running gear is located at this level.

Reversing is carried out by the provision of two cams and rollers for each fuel and starting valve respectively, the ahead cams being brought in contact with their rollers or the astern cams with the astern rollers as desired by the operation of the control levers.

A refinement of some value on high powered Diesel engines is the control of the amount of injection air admitted to the fuel valves at varying speeds.

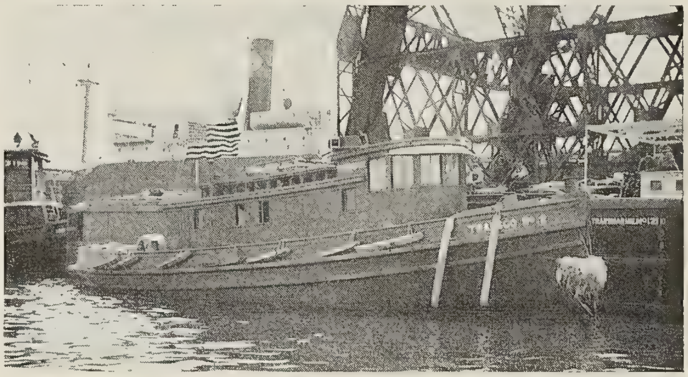
Diesel-Engined Tug for New York Barge Canal Proves Economical

With the completion of the *Transco No. 2,* the first of three Diesel-engined tugs to be placed in service this year on the New York State Barge Canal by the Transmarine Corporation, an opportunity is given to compare the relative advantages of Diesel-engined and steam driven tugs.

The *Transco No. 2,* which was built by the C. Hiltebrant Dry Dock Company, Port Ewen, New York, is 67 feet 6 inches long and 17 feet 6 inches beam. Propulsion is by a heavy duty, four cycle, reversing gear type, Nelseco Diesel engine supplied by the New London Ship and Engine Company, Groton, Conn. The engine has eight working cylinders, 9 inches diameter and 12½ inches stroke, and develops 240 horsepower at 350 revolutions per minute.

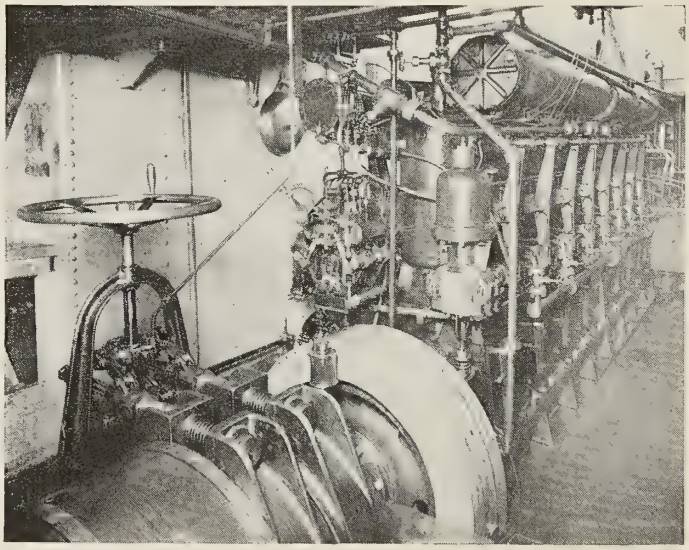
Trials of the vessel were conducted on May 14, consisting of a run on the Hudson River from Kingston to Albany where she was to enter the service of the Transmarine Line. On this run a speed of 11.3 miles per hour was attained on an average fuel oil consumption of 10½ gallons per hour and an average lubricating oil consumption of 0.45 gallon per hour.

On May 16 the vessel took a tow of five barges at Albany and proceeded up the canal. Meeting an eastbound tow at Little Falls, the tugs were changed and the *Transco No. 2,* taking the eastbound fleet, arrived at Pier 6, East River, New York, about 6:00 P. M. on May 23. A day later she left New York with a tow of five barges bound for Buffalo.



New York Barge Canal Tug Fitted with Diesel Type Propelling Engine

On steam tugs of the size suitable for use on the canal, it is necessary to stop for fuel about once every 24 hours. On actual test it was found that the cost of fuel for operating the *Transco No. 2* with her tow averages about 60 cents per hour; while steam tugs of similar horsepower, with the cost of coal at the present price, runs about $4.00 per hour. The time saved by avoiding the frequent stops for taking fuel and disposing of ashes is considerable and the fact that the tug is ready for operation at full load in one minute after word is given are features of great importance as well as the fact that no time is lost due to low steam pressure when cleaning fires.



240 Horsepower Nelseco Diesel Type Engine on Tug Transco No. 2

With this type of Diesel-engined tug, operating at something like 15 percent of the fuel expense of a steam tug and with approximately 250 percent more power available than in the steam tug, not only can higher towing speeds be obtained but also the barge fleets can be more effectively controlled when maneuvering.

System in Shipbuilding

By O. D. Treiber*

This article describes a method of controlling the productive elements in a shipyard where, due to the many varieties of work performed, an intelligent and practical system of management is of the utmost importance.

IT is no easy matter to control the activities in a large shipyard in such a manner that an adequate return in production is secured for the money paid to about forty-five classes of workmen which make up the twenty-five to thirty departments comprising a modern plant.

Such a control is highly essential, however, in order that the thousands of operations necessary to the construction of a modern ship may be properly coordinated with a view to attaining the maximum efficiency. Proper control is also desirable as a means of following the progress of the work at all times, thus insuring its completion within a time allotted and permitting the preparation of an accurate financial statement at any time or stage of the construction period.

The shipyard in which the work has been systematized to accomplish the above results in a sound, practical manner is conducting its business on a solid basis and is undoubtedly assured of steady work regardless of how keen competition may become.

The following system was developed by the author and successfully applied in the administration of a yard in which ships aggregating a total cost of ninety million dollars were constructed.

In developing this system the aim was to devise a method of control which would be simple and effective, which would be economical in installation and operation, flexible enough to expand and contract with the business in hand without confusion and which could be gradually introduced in an established yard without disrupting the organization or work under way during the time of its inauguration.

Principal Plant Divisions

Under the system of administration hereinafter described, the plant is divided into four principal divisions known as the sales, accounting, material and production divisions. In view of the fact that this article is intended to deal principally with the production problems met with, the sales and accounting divisions are not discussed and the material division, which has such an influence on production, is taken up only in so far as its functions affect the production division.

Organization

As the organization of a plant is usually built to suit the ability and capacity of the executive and departmental heads, to which is entrusted the carrying out of the firm's policies, no fixed rule can be established which will be applicable to all cases.

The system which follows, however, is such that it may be applied to any form of organization.

Of great value, in any event, is the construction of an organization chart defining graphically the duties, authority and responsibility of all executives, department heads, foremen and assistant foremen. A chart of this nature will insure that every person in the organization knows to whom and for what he and all others are responsible and will prevent the overlapping of authority which is so often the cause of many operations being neglected because of no definitely placed responsibility. By this means a great deal of misunderstanding and shifting of responsibility, with attendant confusion, is eliminated and a great deal of the trouble that makes systematic production difficult avoided.

Material Division

The material division is charged with the purchase and follow up of all material, receiving, storing and disbursing, material ledger accounts and the adjustment of excessive, deficient and damaged material accounts. It should be supervised by one man who has no other responsibility and can give his entire time and thought to perfecting his organization so that it will function correctly and efficiently.

The activities of the material division are divided among several departments, as follows:

A purchasing department which places the orders for all material.

A follow-up department charged with taking care of deliveries, cancellations and replacements, changes in routing and the adjustments of differences in material accounts.

A receiving department which receives all material and dispatches it to the proper store, checking the material delivered against the invoice and purchase order and reporting any discrepancies to the ledger and follow-up departments.

A store department which is responsible for the proper storage and care of material and also for its delivery to the production division when required.

A ledger department which is held strictly accountable at all times for records showing the status of material ordered, the kind, grade, size and quantity of material on hand, where it is stored and what portion is reserved, with specific information relative to the job for which such portion is reserved and the date it will be required.

The ledger department is the principal department in this division. It is the only place from which material is issued to the workmen or from which information about material may be obtained. The ledgers should be kept in one office centrally located in the plant and there should be a ledger for each class of material. The system is such that this work can be done by one man or divided among a number, determined by the volume of business in hand.

Procedure Followed in the Material Division

Bills of material are prepared in the drawing office and sent to the planning department where notations are made against each item stating whether it is to be made in the plant or purchased already finished and the date it will be required. These bills of material are then sent to the ledger department of the material division where each item is checked in the ledgers. If the material is found to be on hand it is so indicated on the bill of material in a column provided for that purpose and a note made in the ledger that the material is reserved, giving the bill of material number, job number, amount required and the date it will be needed by the production division. If the material is to be purchased it is so indicated on the bill of material and is posted in the ledger as material to be purchased, notation also being made showing the bill of material number, job number, amount and the date required. These bills of material are then blueprinted and copies sent to the purchasing department, receiving department and to all the departments in the production division that will be concerned.

Fig. 1

The purchasing department places purchase orders for the items specified in the bills of material. The dates that the materials will be required, which are noted on the bill of material, are guides for placing orders so that such material will be available when needed and at the same time guarding against the accumulation of material in the plant that will not be needed for a long time and tying up capital with a possibility of loss through depreciation in value. Copies of purchase orders are sent to the ledger department and receiving department. At the ledger department the purchase order number, date it was placed and the date the material should arrive are posted in the ledgers.

The purchase order is then placed in a calendar file so that it will be brought automatically to the attention of the follow-up department in order to insure prompt deliveries.

Should the follow-up department engage in correspondence relative to material ordered, copies of such correspondence are given an identification number and placed in active file. The identification number is entered in the ledger and on the purchase order in the calendar file, so that complete information regarding material is available at all times from the ledger or the calendar file.

Material arriving at the plant is received by the receiving department, where it is checked against the invoice and the purchase order. Any differences between the invoice or purchase order and the material received are reported to the ledger and the follow-up departments for action.

The material is then dispatched to the proper sectional store and the invoice and purchase order sent to the ledger department where the receipt of the material is posted in the ledger with the place of storage. If the material checks with the invoice and purchase order, the ledger clerk removes the purchase order from the calendar file and the correspondence from the active file and places them in an inactive file for future reference should occasion require. The purchase order and invoice, which the receiving department used for checking the material, are then dispatched by the ledger department to the accounting department for payment.

Store orders are made in quadruplicate by the production division. One copy is retained by them and the other three are sent to the ledger department where the items are looked up in the ledgers to ascertain whether the material is on hand and, if so, in which store it is located. This location is indicated on the three copies by the ledger man who signs them, keeps one copy and sends the other two to the proper store where the order is filled. The storekeeper delivers the material and secures the signature, on these two orders, of the party receiving it. He then signs them himself and sends one copy to the ledger department, keeping the other as his order and receipt for the delivery of the material. The ledger clerk checks this returned copy with the one kept by him when he first endorsed the order and after checking off the material in the ledger sends the store order to the accounting department.

material, lack of inter-departmental coöperation, unbalanced department organization and indifference on the part of the workmen, due to lack of definite instructions as to what to do, when to do it and how to do it.

Responsibilities are also very often assigned to foremen for work which should not properly come within their jurisdiction and which it is impossible for them to supervise efficiently. The following method of administration is designed to overcome these losses with a view to maintaining harmony and efficiency in the plant.

Planning Department

All the activities throughout the plant which involve direct labor expense are directed, scheduled, rated, coordinated and controlled by the planning department which determines in advance when and how every operation that contributes to the production of a vessel will be done. This department is by far the most important one of all those in the production division.

In about the same manner that the detail plans for a design are prepared and made to coincide in the drafting room, so is the construction planned in the planning department, with a view to coordinating the work in all departments and insuring orderly progress.

This planning is done for all departments in one office, centrally located, by men who are rated as departmental executives. Their work actually directs and controls production. They are therefore held responsible for the efficiency of their respective departments and their authority is in keeping with this responsibility.

Special Equipment for Planning Office

To facilitate the work of the planning office a card rack is provided which is known as a calendar file. It is made as shown in Fig. 1 with pockets to take cards such as shown in Figs. 2, 3 and 4. These pockets are made in sections of six in a row, arranged to fit in slides on a large frame. The sections may be removed from the slides at the left and inserted again at the right, moving all sections to the left when one is taken out. Each vertical row of pockets is for one day and each section for one week, consequently there is one section to be removed each week. There should be twelve to fifteen sections representing that many weeks, but in some cases more sections will be of benefit. Vertically the rows are arranged for the different departments and foremen, as shown in Fig. 1.

A similar calendar file is provided for the office of each department or foreman with rows of pockets for a machine,

Fig. 5

group of machines, branch or section of the department, man, gang or squad.

Many of the departments will not need more than one row of thirty or forty pockets.

Application of the Planning System

For the purposes of the planning department the work entering into the production of a vessel is divided into two principal classes, manufacturing and assembling.

Manufactured jobs are those covering specific articles or items made in the pattern shop, foundry, machine shop, forge shop, boiler shop, joiner shop or sheet metal shop. These jobs represent such items as hawse pipe pattern, hawse pipe casting, fore foot casting, steering engine, ballast manifold, forged stanchions, boiler, clothes locker, berth with drawers, sheet metal vegetable locker, etc.

Assembling jobs are those done throughout the yard, assembling parks, building slips, fitting out wharf, pipe shop, copper shop, anglesmith's shop and plate and angle furnace shop. They represent specific portions of work to be done by a man, gang or squad and the work is such that the artisan will not be interrupted from the time he starts until the job is finished. In other words, the work can be completed by one man or gang without depending upon assistance from several different crafts.

These assembling jobs may be such as laying down, fairing up and scrieving in the forebody on the loft floor, to be complete in every respect including plate edges; laying out holes in tank top and bulkheads for bilge, ballast and fuel oil piping; installing boiler mountings; bending and fitting main steam pipes; setting up keel and bilge blocks; riveting bulkhead number 54, including clips, stiffeners, brackets and flanges of bounding bars to bulkhead; boring stern frame for stern tube, etc.

Assembling jobs are charted as shown in Fig. 5, the work of each foreman being listed on a separate sheet. Estimates of the time needed and the number of men required are indicated in the proper columns at the left. The period during which the work shall be done is next indicated by an X in the squares at the right under the dates the job should start and finish. The assigning of the jobs to a date or period is done so that the work in all departments will be undertaken in proper sequence and at such times as will meet the demand for efficiency and economy in production.

Manufactured items are charted as shown on Fig. 6, and assigned dates for completion similar to the assembling jobs. These dates must agree with the assembling charts which have already been made out. Duplicate cards as shown in Fig. 2, are then prepared for each manufactured job or item. One of these is filed in the planning office calendar file under the date the item should be finished and ready for assembling and the other is sent to the department that will do the work. When the item is finished, the shop card is returned to the planning department serving as a notice that the work is done.

The manufactured items are then subdivided into specific jobs for a machine, man, gang or squad, and these jobs written on cards as shown in Fig. 3, four cards being provided for each job. One of these cards is typed on the face of an envelope, which serves as the original, the duplicates being obtained by inserting them in the envelope with carbon paper between. On these cards the jobs are broken up into operations and the allowable time for performing each operation indicated at the right. The cards also show a description and sketch of the part to be made with instructions in detail, the date to start and finish, drawing number, bill of material number, machine number or department to which the job is assigned, rate, amount, location of material needed, and where the item is to be sent when finished.

One of these cards is filed in the calendar file in the planning office under the date the job is to start and on the row for the shop or department to which assigned. The other cards, including the one on the face of the envelope, are sent to the department assigned the work where they are filed in a calendar file under the date the job is to start and on the row for the machine, group of machines, department branch, man, gang or squad that will carry it out. Fig. 6

foreman then has his work laid out for him well in advance and assigns the jobs to the workmen in the sequence that they come in the file which conforms to the order laid out by the planners. No harm will result from doing these jobs ahead of schedule dates, but delays are likely somewhere in the plant if a job is not finished on schedule time. The foremen are held responsible for completing work on time and for advising the planner of any delays that seem likely to occur, the necessity for progress men being eliminated in this way. By the above means, the foreman in charge of the men has written instruction in the form of job cards of what to do, when to do it and how to do it. The foreman that cannot follow up these job cards or orders should be replaced.

After the assembling jobs are written on the charts as previously described, they are also written on job cards as shown in Fig. 4. The original is made on the face of an envelope, as described for the manufactured items, copies being provided for the foreman directly in charge of the work, for the planning department, and one copy for each workman. The original on the envelope is for the time-keeping department. These job cards show a description of the job with such instructions as may be necessary to have the foreman and workman understand exactly what is required. The card also shows the name of the foreman responsible for the work with his department symbol, the date to start and finish the job, the number of men required, compensation rate and time allowed to do the job, number of pieces, drawing number and bill of material number. Spaces are provided on the card for punching the starting and finishing time and date with a time clock, and for indicating the amount of time actually taken to do the job, amount of bonus, the workmen's names and numbers and for the signature of the foreman under a printed statement that the job has been completed according to instructions.

The job card for the planning department is filed in the calendar file on the row of the department responsible for the work and under the date the job should be started. The other copies, including the original, are dispatched, with material orders necessary, to the office of the department which will do the job and filed in a calendar file under the date the job should start. These calendar files do not need more than thirty or forty pockets, and for small departments the cards may be filed in an ordinary folder such as a letter file. In this manner the work is arranged for every department and the foremen know exactly what to do and when to do it in order to keep things moving according to schedule and prevent delays which are liable to upset the work of other departments. The foremen are held strictly responsible for completing work on time and for advising the planner immediately should delay from any cause seem likely.

Time-Keeping System

As the direct labor charges form a large percentage of the cost of work, no system will function satisfactorily unless means are provided for accurately keeping track of and following up these charges. The following, therefore, is an important part of the system.

A time card is provided for each man each day with his name and number printed thereon. It is put in a case at the entrance gate before the workman arrives. This card is a three part card made as shown in Fig. 7, so that it can be cut in three parts.

The first part is for the time-keeping department and shows the man's name and number, the symbol of the department in which he works and spaces in which to punch the time and date of entering and leaving the yard; also the job card number, actual number of hours worked during the shift, date, time of starting and finishing and the foreman's name under whose supervision he comes.

The second part is for the accounting department and shows the date, workman's number and department symbol, number of hours worked, rate, amount and the charge number or symbol.

The third part is for the planning department and shows the workman's name, number and department symbol, number of hours worked, rate, amount, number of job card to which the time is charged and the dates or periods the job was scheduled by the planning department to start and finish.

When the workman enters the gate at the beginning of a shift he removes his card from the case and punches the time with a time clock. He then turns the card in to his foreman or shop timekeeper, who fills out the blank spaces during the shift and returns it at the end of the shift. The workman then punches the card with the time clock as he passes through the exit gate and leaves it in a box for the timekeeping department which cuts the card into the three parts and sends each part to the department where it belongs. The parts for the timekeeping and accounting departments are cared for in a manner quite well known and not covered here. The part for the planning department is put into the job card envelopes in the calendar file, these envelopes having been returned from the foremen's offices when the job was assigned to the workmen as described below. The planning department, therefore, has a complete record of the time and cost of each workman on every job.

Fig. 7

Carrying Out the Work

The jobs on file in the offices of the foremen or departments are assigned to the workmen in the sequence in which they appear in the file, but not necessarily on the date as long as it is possible to do the job advantageously and causes no interference with other departments. However, care should be taken that they are started, and particularly finished, by the dates given as failure to do this might cause delay in some other department and have more or less bearing on the delivery of the vessel. The foreman in charge of the men assigns these jobs and is responsible for having them completed on time or for advising the planner of any possible delays in time to rearrange the schedule.

When a job is assigned the workmen's names and numbers are written on the cards and the starting time and date punched on them and also on the workmen's time cards and the foreman retains his copy as a memorandum of the work being done under his supervision. The original on the envelope is sent to the planning department where it is filed in the calendar file with the copy already in the file as described above and serves as a notice that the job is started.

The receipt of time cards should immediately follow and these are placed in the job card envelopes each day. These time cards are evidence that the work is progressing and will also quickly show up any excessive charges against a particular job.

Each day the job cards in the calendar file are moved one pocket or one day ahead. If there is a planners' copy of a job card in the file under the previous date that has not been inserted in an envelope, it is noted at once and in this way the progress in any and all departments automatically shows up.

Upon the completion of the job, the foreman inspects the work to see that it is done properly, then signs the workmen's job cards and his own. The workmen retain their job cards to present to the paymaster for payment and the foreman sends his copy to the planning department where it serves as a notice that the job has been completed. The job card envelope is then taken out of the file, the actual amount of time and money expended is totaled up from the time cards in the envelope. These totals are then written on the planner's copy of the job card and filed away for reference in planning and estimating the cost of new work. The totals are also written on the envelope sent in by the foreman and it is then dispatched to the time keeping department. After checking the figures and computing bonuses, the time keeping department reports to the paymaster the amount due the workman when he presents his job card.

Compensation

The character of work carried on in a shipyard is such that a uniform system of compensation, except that based on hourly or daily rates, is practically impossible. Hourly or daily rates are not conducive to economy and while piece-work prices can be established in many cases, there are others where such a basis is most difficult to apply. Hence, there are usually a number of methods applicable to work in different parts of the plant, the particular method in each case being determined by the operations involved.

Among the methods for compensation successfully applied with the system outlined are the direct bonus, time bonus, split time bonus, contract, piece work and piece work in berths.

Berthing is very well applied in the construction to bolting up, drilling and reaming, riveting, chipping and calking, packing, painting and cleaning. Berth means location or place and berthing is locating or assigning a specific place or part of a vessel to a man, gang or squad to complete in the sequence in which it is planned and in a manner that will not require any going back for small portions of the work carelessly left unfinished, as odd jobs are expensive after the workman has gone to some other part of the vessel or yard.

The standard form of job card is used for berthing and the workmen are held responsible for the completion of their berth.

The foremen directly over the men receive bonuses based on the amount of bonuses paid the men under their supervision and are penalized for passing any work that has to be done over in whole or in part. It is therefore in a foreman's interest to have his men attain the highest efficiency possible consistent with satisfactory work.

The planners are men of high standing in whom great confidence is placed, though perhaps not more than is usually placed in a department head of a large organization. These men should receive bonuses based on the earnings of the company because they exert a great influence on efficient and economical production.

The bonus for some work should be based on bonuses paid for other work upon which it is dependent. Such a job may be the lining up of boilers which is done by machinists while the work of putting the boilers in place is done by riggers who cannot clear away their gear until the boilers are permanently located.

The machinist has very little work to do, but he can cause a lot of delay if he is not on hand with the necessary tools when he is required by the riggers. When it is to the machinist's interest to have the riggers finish the job quickly, he is more willing to render as much assistance as possible and at least will be on hand to see that there is no delay on his part.

There is scarcely an operation in the building of a vessel to which some form of premium compensation cannot be applied. Where such is done, labor efficiency will take care of itself, provided a reasonable amount of care has been exercised in selecting men to build and maintain the organization.

The preparations of time estimates or rate setting for each job should be done with care and can, if desired, be assigned to a special group of men known as rate setters. The basis for figuring rates should be an analysis of information concerning operations, piece work rates or time studies which has been prepared from returns on previous work of similar nature.

A thorough knowledge of the work to be done is prerequisite as is also a reasonable amount of good judgment.

The records compiled in the planning office as previously outlined are the most accurate guides for making rates which become practically standard after the system has been used for a while. In fact the work of planning and rating gradually becomes a matter of reapplication from one contract to another by simply making such changes as are found to be advisable and which are necessary to meet the plans and specifications of the new contract.

Summing Up

The foregoing is a simple system that can be gradually introduced into any established organization without disrupting the personnel or interfering with production during its inauguration.

The department head may become the planner for his department and his assistant the executor of his plans; the sub-foremen become the assistants of the executor and the clerk of a department may become the planner's clerk in the planning office, caring for the job cards and time cards in the calendar file and such other routine as there is to do. The department timekeeper may remain in the same position looking after the time cards of the workmen and performing such other duties as may be required. The system is flexible so that where all the persons mentioned are not required the work can be arranged to provide for one man doing as much as the volume of business will permit. Where only a few men are employed in his department it would not be impossible for the planner to do all the work that the system

requires. It should be kept in mind, however, that the planner is the master of his craft.

In conformity with the above arrangement, the assistant superintendent would become the head of the planning department and the superintendent the production manager.

Conclusion

The chief advantage of the foregoing system is that it provides a method of positively controlling every activity involving direct labor expense and that it will reduce overhead in addition to insuring an orderly sequence of the work. With this method there is no such thing as "bluffing" along anywhere in the organization because, if a workman, foreman or department head cannot carry the responsibilities of his position, the fact begins to show very soon in the figures returned. Every workman on the payroll is contributing to production by doing work that has been previously planned, scheduled (assigned to a definite date), and rated and which is on record in the calendar file in the planning office.

The planners devote their time to planning their work ahead so that the material needed will be at hand when required and the work will go forward in the proper order and information of possible delays or excessive charges is obtained far enough in advance to allow corrective measures being taken to offset losses.

Reports are made out at regular intervals by the planner's clerks. These can be made in a number of ways to show the actual progress of the work in relation to the planning, the actual cost in relation to the estimated costs, the relative progress of the different departments and the efficiency in any detail that may be desired, extending, if necessary, to each job or man, gang, or squad.

With the information contained in the calendar file an ingenious clerk can compile statistics in reports or graphics that will show most anything that may be desired concerning the production in the plant.

There is actually a detailed cost account available for every job which has been prepared at no extra expense, which is accurate and which will locate leaks and show up inefficiency before there is a loss of any magnitude.

Knowledge of actual costs is most essential when preparing estimates, especially when the competitive bidding is keen and in making up a financial statement the expenditures on work under construction will mean a great deal when compared with the estimated labor costs.

By a physical survey of the plant, it is very difficult to detect the dropping behind of any department until it is really in bad shape and perhaps holding up work in other departments which is sure to cause a loss through workmen standing idle or working to a disadvantage while the department that is behind catches up with its work, if it can. The progress records show the slightest variation and give the department head and superintendent an opportunity to guard against loss from this cause.

There is no part of this system that is not an actual function in a plant without it, but by systematizing the supervision along sound business principles, duplication of effort and uncertainty of action are eliminated.

Activity Shown in Requests for Marine Exhibit Space

Thirty-Eight Companies Given Booth Numbers for Exposition to Be Held November 4-11—Twelve New Members Join Recently Incorporated Association

With America's maritime situation the prominent feature before the public at present, in connection with the ship subsidy bill awaiting definite action by Congress, it is interesting to note the steadily growing interest in the Marine Exposition scheduled for the week of November 4-11 at the Grand Central Palace, New York City. The latest announcement from the American Marine Association, under whose auspices the exhibition will be held, states that the incorporation of the association has now been completed, the corporate name being American Marine Association, Inc., and that 38 companies actively interested in the construction, repair and equipment of vessels have already signified their intention of taking part in the show and have been officially alloted space. It is also stated that 12 new members, many of them among the largest concerns in the marine industry, have recently been added to the membership of the association.

The early response on the part of exhibitors is considered as highly gratifying to the exhibits committee, the latter being composed of Gardner Cornett, of the Pneumercator Company (chairman); K. W. Heinrich, Bethlehem Shipbuilding Corporation; Frank J. Shipman, Texas Company; W. H. Raab, Todd Shipyards Corporation, and A. S. Hoffman of the Griscom-Russell Company. The official allotment of space and booth numbers made at a meeting of the exhibits committee held on June 1 are as follows:

American Manganese Bronze Company, 2; General Electric Company, 3, 4, 5, 6; C. H. Wheeler Manufacturing Company, 7; Pneumercator Company, 8; Victor Engineering Company, 12; C. A. Woolsey Paint & Color Company, 13; Peabody Engineering Company, 15; The Texas Company, 16; McCormick, McPherson & Lapham (San Francisco, Cal.) 17; Ashton Valve Company, 21; The Sperry Gyroscope Company, 22, 23, 24; W. & J. Tiebout, 29; Pantasote Company, 30; Lee & Simmons, Inc., 31; The Crandall Engineering Company, 38; The Babcock & Wilcox Company, 42; Simmons-Boardman Publishing Company, 51; Ellcon Company, 53; Northern Fire Apparatus Company, 55; Coen Company, 57; National Malleable Castings Company, 58; Scovill Manufacturing Company, 59; Griscom-Russell Company, 60; Diamond Power Specialty Corporation, 63; The Superheater Company, 66; Crane Company, 68; Bethlehem Shipbuilding Corporation, Ltd., 70, 72; The Sterling-Cooper Corporation, 71; Todd Shipyards Corporation, 84, 88; Westinghouse Electric & Manufacturing Company, 85, 87; Marine Decking and Supply Company, 96; Lunkenheimer Company, 99; Worthington Pump & Machinery Corporation, 100; Kingsbury Machine Works, 101; The H. E. Boucher Manufacturing Company, 108; B. F. Sturtevant Company, 111; Crane Packing Company, 305; The Stamford Foundry Company 327.

It is also announced that Valentine & Company, New York City, has also made a reservation of space and a number of other concerns have already signified their intention of exhibiting.

The Association is conducting a drive for new members, the results of which to date have been highly gratifying to all concerned.

The office of the association is in Room 1624, 15 Park Row, New York City. Telephone, Barclay 5458.

Figs. 1-6.—Arrangement of Turbines and Double Reduction Gears on S. S. Melmore Head, Showing Nodal Drive

Double Reduction Gears in the S. S. Melmore Head*

Successful Running of the Gears Secured by Tuning of Periodicities of the Rotating Masses of the System

By J. Wilkie

In the controversy which has centered round the problem of double reduction gears during the past few years, it has been exceedingly difficult to collect reliable information regarding the troubles which have been experienced with this type of drive. Excessive noise in the engine room, with hammering of the gears, would appear to have been all too common in gear-driven ships. When this is the case, heavy flaking of the gears in the neighborhood of the pitch line occurs, with grooving and deformation of the teeth and occasional fractures of the teeth, which clearly suggest fatigue of the material.

While this must have been the experience of many, there are those who assert that there is nothing wrong with double reduction gearing. If this is the case, one naturally wonders why it should be necessary to run many of our geared ships at reduced powers, and to design the gears for new installations at half of the original tooth pressures, thereby greatly increasing the weight and cost of gears.

With so much conflicting evidence, there is good ground for the appeals which have been made for giving all the facts available regarding the performance of double reduction gears at sea.

By the courtesy of the directors of the Ulster Steamship Company and the directors of Messrs. Workman, Clark & Company, of Belfast, the author is enabled to give a detailed account of the troubles experienced with double reduction gearing in the *Melmore Head,* together with a description of the methods recently adopted to overcome these troubles.

The *Melmore Head* is a single screw steamer of 2,500 shaft horsepower driven by double reduction geared turbines. This ship was built and engined by Messrs. Workman, Clark & Company, and delivered to her owners in September, 1918.

Fig. 1 shows in plan the arrangement of the turbines and gear, while Fig. 1a shows the relative positions of the pinions and wheels. The revolutions of the various elements are:

High pressure, and intermediate pressure turbines and pinions	3,600 per minute
Low pressure turbine and pinions	2,400 per minute
Second reduction pinions	560 per minute
Main shaft	70 per minute

The second reduction gears are designed for a working pressure of 1,000 pounds per inch width of tooth, and at 70 revolutions per minute the constant $P/\sqrt{d}$ is 274. The machinery is placed amidships, and the length of the main propelling shaft from the gear to the propeller is 144 feet.

In her regular service across the North Atlantic the *Melmore Head* makes the outward voyage in ballast and the homeward voyage loaded.

As several sets of gearing have been fitted to the original gear case at different times, these will be designated by numbers in order that the sequence of events may be clearly followed. Particulars of the various gear arrangements are given in Table I.

NOTE.—Figures are inserted where the parts have been renewed.

Gear No. 1

In erecting this gear in the shop every precaution was taken to ensure accurate alinement, and the same care was taken to ensure this alinement being maintained when the gearing was transferred from the shop and put in position in the ship.

The running of this gear on the trial trip was very unsatisfactory. The noise in the engine room was deafening, while at the gear case it was evident that the gears were hammering each other in a most alarming fashion. This hammering of the gearing was not confined to any one particular speed, but could be distinctly traced at all speeds up to the maximum.

It was confidently expected that after a short time at sea the general conditions in the engine room would improve, that the teeth would become properly bedded to each other and that the hammering would cease. Such a state of affairs, however, was never realized and each succeeding report from the chief engineer merely indicated that matters were getting worse. This was confirmed by personal observations on the part of the author. It has been his practice, until quite recently, either to meet the ship on her arrival in Belfast Lough or to accompany her to her coaling ports on the Clyde or Bristol Channel, in order to trace the various developments in the problem.

*Paper read at sixty-third session of the Institution of Naval Architects, London, April, 1922.

A careful examination of the gearing at the end of the first voyage showed a considerable amount of flaking of the teeth and grooving at the pitch line. By the end of the second voyage this had increased considerably, and in addition, a sharp protruding edge was being formed on the teeth of the second reduction gears. This was removed before the third voyage was started. During the second voyage, also, considerable trouble had been experienced through choking of the oil filters by steel particles from the gearing and, in addition, a slight fore-and-aft movement of the second reduction pinions was detected.

The outward portion of the third voyage was safely completed, although the choking of the oil filters and the movement of the second reduction pinions were increasing. When 400 miles of the homeward voyage had been covered, however, the movement of the pinions had become so violent and the consequent pounding of the gears and vibration of the gear case so severe, that speed had to be reduced, and Norfolk, Va., was made with very great difficulty. In this port, temporary thrust pads had to be fitted to the ends of the second reduction pinions to hold them in position. By this means it was possible to run the machinery at a speed sufficient to maintain steerage way on the ship while she was being towed home by another of the company's vessels.

Between September, 1918, and April, 1919, when this gear collapsed, approximately 25,000 miles had been covered at full power. Particulars of the speeds and revolutions are given in Table II.

Two reasons were put forward for the failure of this gear; these were inaccuracies in cutting and faulty alinement. As regards alinement, great care had been taken with this in the course of construction, and when the gear wheels were removed it was again checked by mandrils in the gear case bearings and found to be correct. This being the case, the whole cause of the trouble was attributed to inaccurate cutting of the gears. It was decided, therefore, that new gears of finer pitch (particularly in the case of the second reduction gears) should be put in hand, and that these should be cut by a different firm of gear cutters.

Gear No. 2

The gear wheel and pinions in this case were mounted in the gear case on board the ship. The alinement of all the parts was carefully examined, and all concerned (including the gear cutters) were satisfied as to the accuracy of the work. Had any doubt existed, this was removed by an examination of the tooth markings after the trials had been run.

The performance of this set of gearing on trial showed very little improvement on the performance of the first set. The noise in the engine room was still excessive, and the hammering of the gears was much in evidence. Nevertheless, the ship went on her fourth voyage at her originally designed speed.

While this gear lasted the rattle and roar in the engine room remained undiminished. The gears were examined at the end of each voyage and, although the wear on the teeth did not appear to develop as rapidly as in the first gears, signs of the old troubles with flaking and grooving were not wanting.

At the end of the fourth voyage the pressure of the oil supply to the gears was increased by raising the level of the gravity supply pipes to the top of the engine room casing. No appreciable change in the noise resulted from this alteration, however, and the fifth voyage was completed under the similar uncomfortable conditions of previous voyages.

The sixth voyage of the ship, and the third with this set of gearing, saw the collapse of Gear No. 2. On the passage up the St. Lawrence River, the second reduction gears stripped half-way across the face of each pinion and wheel shroud.

Between August and November, 1919, this gear had completed approximately 14,000 miles at full speed. Temporary second reduction gears were dispatched to Canada, and after these were fitted up the ship returned to Belfast at about half power.

An examination of the fractured teeth of this second set of gears showed that all the teeth had been broken off sharp at the roots without any sign of elastic deformation. From this it was concluded that the material had given way under fatigue stress and this was subsequently confirmed by tests carried out at the steel works. It appeared, therefore, from an examination of all the facts available that stresses of a nature or magnitude not anticipated in the original designs were being transmitted through the gears and that lower tooth pressures would have to be employed, if the gearing was to be made to work satisfactorily.

Accordingly it was decided to re-design the gear case and to limit the maximum tooth pressure to 500 pounds per inch width. This gear was actually completed, but, as subsequent developments proved, it was never necessary to have it installed in the ship.

Gear No. 3

As the demand for tonnage at this time was very great, a third set of second reduction gearing was installed to work in conjunction with the primary gears retained from Gear No. 2. With this arrangement the ship was to be kept in commission at reduced power until the new gear case was ready.

Three voyages (Nos. 7, 8, and 9, Table II.) were completed with this arrangement before any modifications were made. The average speed over these three voyages was 7.5 knots at 48.5 revolutions, giving a value of 132 for the constant $P/\sqrt{d}$.

The running conditions with this gear, even at reduced power, were not too satisfactory. While the engine room conditions were certainly tolerable, there was clear evidence of the former hammering action of the gearing taking place. The intensity of this action was, of course, greatly diminished owing to the reduced speeds of rotation of the wheels, at the same time a reduction of the constant from 274 to 132 had not produced that smoothness of running and absence of noise so essential for the preservation of the gear for any considerable time.

In the author's opinion the method of attacking the gearing problem by simply reducing tooth pressures was not satisfactory. It seemed to be more or less a shot in the dark supported by no sound argument, and was likely to prove a tedious and costly method of experiment.

From a careful study of the observations made from time to time on the *Melmore Head,* the writer came to the conclusion that the gear transmission system as a whole was dynamically unsound and that, if satisfactory running of the gears was to be obtained, some consideration would have to be given to the inertia effects of the various rotating masses and particularly to the effect of torsional vibrations of the propelling shaft, arising from propeller action in a variable wake.

Shortly after the third gearing arrangement was installed, Professor Smith was called in to investigate the problem on behalf of the builders and the writer became associated with him in carrying out the subsequent changes which were made from time to time.

The mathematics of the problem have already been put before you in Dr. Smith's paper on "Nodal Arrangements of Geared Drives." The writer will, therefore, confine his remarks to a description of the various changes made on the *Melmore Head.*

It had been observed at various times that the hammering effects in the gear appeared to be most severe at the low pressure side. The reason for this was believed to be that, because of its mass and the rigidity of its connection to the gears, the low pressure turbine was unable to keep step with the fluctuations in speed of the main wheel which resulted from torsional oscillations of the main shaft. Parting of the teeth would, therefore, occur with hammering when contact was resumed. It was decided, therefore, as a first experiment to adjust the shaft connecting the low pressure turbine to its primary pinion in such a way as to make the periodicity of the free torsional oscillations of the low pressure turbine about the main gear wheel equal to the periodicity of the free torsional oscillations of the propeller about the main gear wheel.

Gear No. 4

To carry out the idea of tuning the low pressure turbine and its driving shaft to the same periodicity as the propeller and propeller shaft, the pinion shaft A in Fig. 1 was removed and replaced by a hollow bored pinion shaft with an internal flexible driving shaft as illustrated in Fig. 2. The principal dimensions of this arrangement were A = 2 9/16 inches, B = 2 11/16 inches, C = 4 1/16 inches, D = 4½ inches, L = 7 feet 10 inches. The stress on the internal shaft was 9,900 pounds per square inch. The collars on the internal shaft were made a sliding fit in the bore of the pinion shaft and were introduced to prevent any possible whipping of the internal shaft.

As the primary wheel on this side of the gearing was badly grooved, it was decided to renew this wheel in addition to fitting the new pinion. *Otherwise it is to be particularly noted that no other change was made on the gearing and that the second reduction gears remained exactly as when originally fitted in arrangement No. 3 at the end of voyage No. 6.*

This arrangement was thoroughly tested on trials run at full power in Belfast Lough. The effect produced in the running of the gear by the introduction of this flexible drive was most encouraging. The hammering of the gears had entirely disappeared at the low pressure side, and instead, a pure rolling of the teeth was produced. The gear case which had previously vibrated considerably was now perfectly steady and generally the conditions in the engine room were comfortable. As was anticipated, of course, hammering was still evident at the high pressure side of the gears, due to the fact that no adjustments had been made on that side.

Although the trials of this arrangement had proved so satisfactory, it was decided to make the next voyage at a speed not exceeding 50 revolutions per minute. The reason for this decision was that the arrangement was purely experimental and of a temporary nature, and the stresses adopted for the flexible driving shaft were unusually high. This voyage—No. 10 in Table II—was successfully completed and at its conclusion a careful examination of the gears showed no grooving or pitting of the teeth. It may be argued, of course, that one voyage of approximately 7,000 miles is too short a period in which to draw any conclusions as to the condition of the teeth. With the first and second gears, however, there was no doubt as to what was happening to the gear teeth long before that distance had been completed.

Gear No. 5

As a result of the experience gained in the first experiment, it was now decided to tune both turbines and their driving shafts to the same periodicity as the propeller shaft. This time the stresses in the driving shaft were reduced from 9,900 to 7,500 pounds in order to provide a sufficient margin of safety for continuous working at full power. Stresses lower than 7,500 pounds were considered impossible in this ship, as the driving shafts would have become too long to be satisfactorily supported.

Pinion shafts A and B in Fig. 1 were replaced by hollow bored pinion shafts with extension sleeves and internal shafts as shown in Fig. 3. The principal dimensions of these shafts were:

	High Pressure Side	Low Pressure Side
A	2½ inches	2 13/16 inches
B	3 inches	3⅜ inches
C	4¼ inches	4½ inches
D	4½ inches	4½ inches
L	10 feet 10 3/16 inches	10 feet 10 3/16 inches

As the length of the high pressure driving shaft could not be made sufficiently long to completely tune this side of the system, it became necessary to increase the inertia effect of the high pressure and intermediate pressure turbines in order to tune them to the same periodicity as the propeller, and to obtain an approximate balance between the two sides of the driving system. This increase of inertia was accomplished by introducing a flywheel between the high pressure and intermediate pressure turbines. The position of the flywheel between the turbines was chosen with the idea of binding the three elements in such a way as to form approximately one rigid mass and thus avoid the possibility of independent vibrations being set up between those three units.

This flywheel with its shafts was a solid forging of 34-38 tons steel, the diameter of the wheel being 3 feet ½ inch, the breadth 9 3/16 inches, and the weight 2,720 pounds. The flywheel is shown in Fig. 4.

This arrangement of flexible shafts and flywheel was fitted up at the conclusion of voyage No. 10. It is again to be particularly noted that *no adjustments were made on the second reduction gears, these remaining exactly as when originally fitted at the end of voyage No. 6.*

Trials at full power were run with this arrangement, and the results were considered to be very satisfactory. The absence of hammering in the low pressure primary gear and at both sides of the secondary gears was particularly noticeable. One defect remained, however, which subsequently proved to be more important than was anticipated. Doubtless many of you were present when these trials were run in Belfast Lough, and you may have noticed a slight vibration at the high pressure primary gear.

When the new pinion and flexible shaft were fitted to the high pressure side, no change was made in the primary wheel. This wheel remained from Gear No. 2 and, as it was only slightly grooved, it was considered that it would run quietly with the new pinion and the flexible drive. On

the trials, however, this condition was not quite realized and a slight vibration developed at the high pressure primary gear.

With this one apparent defect remaining the ship set out on her eleventh voyage, the outward portion of which was completed at an average of 65.3 revolutions. The vibration at the high pressure primary gear had increased somewhat by the end of this outward voyage and, as it continued to increase during the homeward passage, speed was reduced and the voyage completed at an average of 52.7 revolutions.

Gear No. 6

An examination of the high pressure pinion at the end of this voyage showed that it had become grooved in exactly the same fashion as the primary wheel. It was evident, therefore, that to set a new and well-cut pinion to work in a worn wheel and expect quiet running conditions was a mistake, consequently both the high pressure pinion and primary wheel had to be renewed.

The flexible shafts were also withdrawn for examination at this time and it was found that the collar at the flexible coupling end of each driving shaft showed considerable wear. This necessitated a modification of the design and a bearing coupled to the forced lubrication system was fitted as shown in Fig. 6. This is the last modification that it has been found necessary to make on the gears of the *Melmore Head.* Fig. 4 shows the arrangement of the "nodal drive" as applied to the high pressure driving element and Fig. 5 shows the arrangement as applied to the low pressure driving element.

With this arrangement the ship has been in continuous service and is giving complete satisfaction. Up to the time of writing, voyages 12, 13, 14 and 15 have been completed. The average revolutions for the twelfth voyage and the remaining homeward voyages are low, due entirely to the poor quality of coal.

The condition of the gearing is perfect. So far, no "pitting" has appeared on the primary gears and only very light "pitting" along the pitch line of the secondary gears, which occurred prior to the carrying out of these experiments, and has not developed since. There is absolutely no trace of a beat in the gear case while running up to full power.

The second reduction gears have now completed approximately 50,000 miles, 16,000 before fitting the "nodal drive" and 34,000 miles since the experimental work commenced.

The writer would like to draw attention to the fact that all these changes in the *Melmore Head* have been carried out in the gear case originally fitted in the ship in 1918. No alterations have been made beyond those already described in the paper, and consequently the continued successful running of this gear is entirely due to the tuning of the periodicities of the various rotating masses of the system.

In conclusion, the writer wishes to express his indebtedness to the directors of the Ulster Steamship Company, and Messrs. Workman, Clark & Company for placing at his disposal valuable information regarding the *Melmore Head.*

Cement and Concrete for Shipbuilding Purposes—III

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

There are a number of coatings designed to protect concrete surfaces in oil tanks or elsewhere, on the ground that the oil disintegrates the concrete. An inspection made by the Bureau of Standards in 1917 of reinforced concrete oil tanks then in service indicated that such was not the case as far as mineral oils are concerned, and that these oils have no deleterious effect on concrete that is properly cured before contact with the oil. A series of tests subsequently made confirmed this with the possible exception of very light oils, but showed that certain organic oils do have a destructive effect on concrete. For marine service oilproof coatings should be of such a nature as to be unaffected by water.

Materials for Oilproof Coatings

Tests made of perilla oil indicate that it is unaffected by exposure to gasoline, kerosene, crude oil and vegetable oils.

Some oil proof coatings have shellac as a base, with alcohol as a thinner, with a pigment and possibly other materials. Such compounds, while oilproof, are not waterproof, and are therefore undesirable in marine service. These coatings are also apt to be brittle.

Concentrated sulphite pulp mill liquor is also marketed for this purpose. It has good adhesive power on concrete surfaces and gives an oil proof coating, but is softened by water.

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

The coating adopted by the Shipping Board for the oil tanks of their concrete tankers was a high grade of spar varnish, resistant to air, light and water. Very detailed specifications and test requirements were prepared and successfully met by several of the paint and varnish manufacturers. The method of application was:

First Coat—To be applied on concrete which has been treated with magnesium fluosilicate solution and which has been dried at least 24 hours with good ventilation. Thin the varnish by adding 20 percent of volatile mineral spirits and apply with brush or air gun at 60 to 70 pounds pressure, a thin coat covering all portions of the surface, allowing no varnish to flow down vertical surfaces. Allow to dry hard; at least 24 hours being necessary, 48 hours is better. In confined spaces, during the application and during at least the first 24 hours of the drying period, artificial ventilation shall be provided.

First Coat on Other Paints and All Second and Third Coats—Apply the varnish without thinning, with brush, or with air gun at about 40 pounds air pressure. The above remarks as to covering, drying period and ventilation shall govern in all cases.

After about two years of experimentation the coating was modified to require a layer of cheese cloth between the second coat of varnish and a third coat of varnish or of so-called gray enamel, which consisted of 55 to 60 percent of the varnish and the balance of white lead pigment. The application of the cheese cloth on large surfaces, however, was found to be impracticable and its use was abandoned. The varnish itself, as has been mentioned, is difficult to apply in the hold of a vessel, where, even with the most favorable weather conditions, it is hard to obtain sufficient

light and air for proper drying. It is also injuriously affected by alkali salts in the concrete.

The Tentative Standard Specifications require that concrete structures for containing light mineral oils, animal oils, certain vegetable oils, and other commercial liquids shall be given a special coating which shall be applied immediately after construction. Floors or other surfaces exposed to heavy concentrations of such oils or liquids shall be similarly protected. The treatment to be applied shall be approved by the engineer.

The writer is of the opinion that it is neither necessary nor advisable to coat concrete oil tankers as a protection from mineral oil or to coat oil tanks for carrying the oils usually met with except as a protection from water. Apart from the use of penetrating oils or other special applications, coating the surface with thin cement grout should suffice; and such practice has the approval of the Bureau of Standards for oils of about 35 degrees Beaume or greater density. The film of oil deposited on the surface affords some protection against water when the tanks are being used for ballast. Examination of leakage in way of rivets or seams of steel tanks carrying heavy mineral oil shows it to be of the nature of dark colored kerosene; so it does not seem unreasonable to extend the service of the grout coated oil tanks to carrying the lighter oils when necessary.

Materials for Hardening the Surface of Cement and Concrete

As has been stated in the article on deck coverings, cement and concrete surfaces under wear produce a fine powder, and the surface without special treatment is not as wear resistant as is desirable in some locations. This difficulty, which assumes some importance on concrete ships, can be overcome by surface hardening compounds.

Magnesium fluosilicate, either as such or under some trade name, has been used to a considerable extent for this pur-

pose. The Shipping Board used a 7½ percent solution, or 7½ pounds of the anhydrous salt to 100 pounds of water, which was made by diluting their standard specifications for this material, or other more concentrated solution, with fresh water. Their specification reads—

The material shall be clear, colorless solution of magnesium fluosilicate ($MgSiFl_6$) in water. The solution shall contain not less than 15 percent by weight of the salt $MgSiFl_6$ and shall not contain more than 1 percent of any other substance in solution, nor more than 0.2 percent of total chlorine.

The method of application, which was mainly for the purpose of neutralizing the free lime in the concrete, was:—

Apply with a wide brush or with air gun at low pressure, saturating the concrete surfaces, which shall be air dry before the application. Allow the concrete to dry before applying paint or varnish coats. Second application is made only where specified for hardening purposes. Apply 24 hours after the first application.

Some surface hardening compounds consist of a mixture of iron powder and ammonium chloride. It is sprinkled upon a fresh concrete surface and troweled in, or it is mixed with water, kept stirred and scrubbed upon concrete surfaces already set. The iron is supposed to rust and fill the pores of the concrete thus being a waterproofer as well as a hardener, and the ammonium chloride is to quicken the rusting action. Tests made by the Shipping Board showed that the treatment does make the surface harder; but the coating cracks with the concrete, so it is not valuable as a waterproofer.

Materials for Avoiding Trouble from Alkali Salts

Free lime in concrete comes to the surface and acts upon and saponifies the oil in protective coatings, thus destroying coatings of that nature. Avoidance of this trouble was the principal reason for the Shipping Board's use of magnesium fluosilicate solution. The results achieved, however, were of doubtful value. Zinc chloride is another surface application for this purpose.

Integral waterproofers of a siliceous character which are of benefit in this connection have been referred to.

Materials for Frost Proofing Cement and Concrete

The use of such materials in shipbuilding work is usually neither desirable nor necessary but it is well to know that they are available and that they have been the subject of favorable laboratory test as well as the test of actual use in construction on land. Salt has been used to a considerable extent and soda to some extent.

Their requirements are that they shall prevent the freezing and ensure the proper setting of the cement or concrete at the temperatures at which the work has to be performed; that they will not, in the amounts which have to be used, injuriously affect reinforcing steel or the tensile or compressive strength of the cement or concrete; and that they will not introduce any other deleterious factors.

The Tentative Standard Specifications state that salt, chemicals or other foreign materials shall not be used to prevent freezing.

Protective Coating Summary

In a consideration of protective coatings the steps taken in any progressive developments are of value as well as the final outcome. The following tabulation shows in a concise manner some of the Shipping Board's steps in developing coatings for the concrete oil tankers. Column A shows specifications as amended and adopted after about a year of research and test; and column B shows the requirements at the time of the breaking up of the Concrete Ship Section, when the work was turned over to the writer about a year later, with the construction well along. Column C embodies the writer's recommendations for such service.

It is well to note that antifouling oil paints or other oil paints cannot be used to make a satisfactory coating over bituminous paints. The oil and thinners in the former soften and blend with the latter and a very streaked and spotted coat results. When such a combination is exposed above water the outer coat checks and "alligators," due probably to being less elastic than the bitumen coating beneath it.

Asphalt Cement

This is a bituminous composition of the nature of bituminous enamel that is of value for filling in spaces which are subject to vibration, filling in between castings and steel plates which do not lie metal to metal, coating the bottoms of chain lockers, and other service where Portland cement would be apt to crack out or suffer damage. A bituminous priming coat should be first applied.

The Navy formula for the asphalt cement is:—

Ingredients	*Quantities required for* 100 *pounds*
Trinidad asphalt	15 pounds
Paving asphalt	51 1/5 pounds
Vulcanite special or Anchor Rock Brand asphalt	15 pounds
Rosin	1¼ pounds
Slaked lime	2½ pounds
Portland cement	17½ pounds

The asphalts and rosin are melted together, and when thoroughly mixed the Portland cement is added and the mixture well stirred. The fire is then drawn and the mixture is ready for use or storage.

Roman Cement

Roman cement is a natural hydraulic cement made by calcining and grinding a kind of cement rock which usually contains considerable iron oxide, thus giving the cement a red color, also manganese and more alumina than Portland cement. It is quick setting, hard and durable.

This material is of value on boiler room tank tops of oil burning vessels in place of the customary bituminous solution and enamel and is sometimes specified for such service. Spilled oil has a tendency to dissolve the bituminous coating and the fire hazard is also greater where such a coating is used.

Linoleum Cement

This material is of value to cement down linoleum or cork composition tiling and it is put on about ⅛ inch thick.

The Shipping Board Specifications for it are:—

This material shall be made as follows, using these exact relative proportions of ingredients:

Two ounces of real rubber shall be cut in one gallon of gasoline. This solution shall be added to a mixture of:

Thirty-two pounds of Grade A gum shellac cut in seven and one-half gallons of Clear Neutral Denatured Alcohol (No. 1 Internal Revenue Department Standard, 100 gallons grain alcohol and 5 gallons approved wood alcohol) to which solution has been added one hundred and twenty pounds of high grade Whiting.

The whole shall then be ground to an intimate mixture.

The whiting used shall contain no hydrated lime.

The Navy Department specifications for this material are somewhat similar to the above.

Smoothing Cement

Some compositions are required for evening off decks prior to laying linoleum and similar service. The Navy Department formula for such a cement is as follows:

Ingredients	*Quantities required for* 100 *pounds*
Venetian red, dry	10 pounds
Whiting	32 pounds
White lead, dry	16 pounds
Zinc oxide, American, dry	16 pounds
Litharge	16 pounds
Raw linseed oil	1½ gallons
Turpentine	¾ gallon
Japan drier	⅜ gallon

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

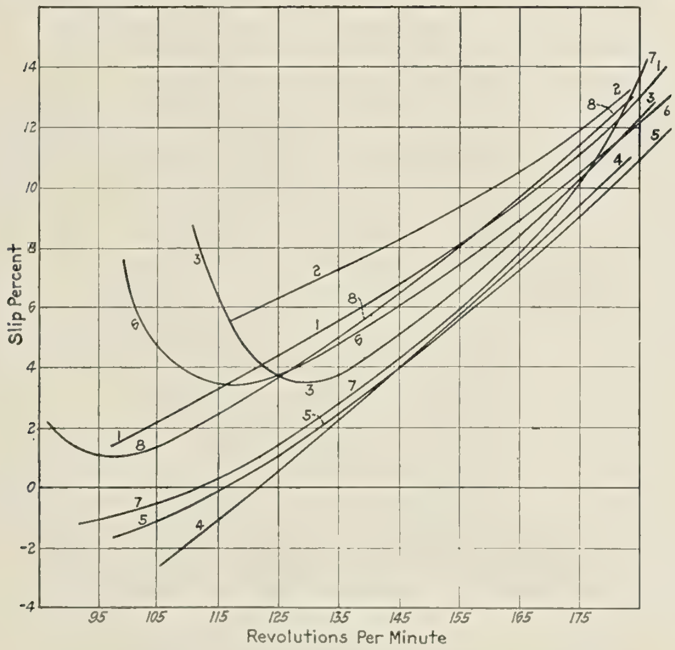
Unexplained Phenomena Developed in Tugboat Trials

Q. (1159).—The following data were obtained from the trial trips of eight boats (similar in all respects and constructed by a small shipyard) of a tug design about 100 feet long over all, 22 feet beam, 8 feet 3 inches mean draft, 260 tons displacement. Propeller 7 feet diameter, by 7 feet pitch, 4 blades. The trial trips were held in a depth of water of 28 to 32 feet, and over measured mile courses usually with a beam wind, over which six or more round trips were made to obtain the data.

In plotting the results obtained, especially the revolution-slip curve, a peculiar feature was noted on some of them, three became negative at slow speeds and three indicated a tendency to reverse, showing a minimum value for the apparent slip increasing either side of this for either an increased or decreased speed. This seemed peculiar, and it was thought that perhaps an error had crept in due to the wheelsman not having steered a straight course over the mile, but had see-sawed over the line.

What reasons would you assign for the characteristics of these curves as here shown, and why negative slip in some cases?

A. (1159).—On the basis of the information furnished, the writer has no explanation to offer relative either to the characteristics of the curves or the development of negative slip at the lower speeds in certain cases. It is possible that



Revolution-Slip Curves

with the aid of model tank effective horsepower curves and a fuller knowledge as to the conditions surrounding the trials of each vessel satisfactory reasons for the phenomena noted might be found.

It is suggested that any one or a combination of all the following might have been instrumental in producing the results obtained.

(a) Variations in propeller characteristics due to lack of uniformity in finish of blade faces.

(b) Inaccuracy in corrections for tide and wind on runs of opposite direction.

(c) Differences in displacement and trim at time of trials.

(d) Foulness of bottom and of propeller. These might easily have been important factors as the effect of fouling either on the vessel's bottom or on the propeller faces might render the relation between the vessel's speed and the revolutions of the propeller very uncertain.

Calculation of Lift of Valve

Q. (1158).—How would you figure the required lift of a valve to equal its diameter when the seat is mitered at a 45 degree angle?

A. (1158).—It is believed that the intent of the question is to ascertain the method of so figuring the valve lift that the flow of water past the edge of the valve disk will equal that through the valve seat. The following is based upon this understanding:

If there were no obstructions to the passage of the water through the opening in the valve seat, such as ribs and

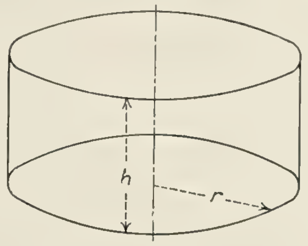


Fig. 1

bosses, and if no allowance were made for the effect of friction, change in direction of flow, etc., the problem would be simply that of finding the altitude of a cylinder such that its area of side is equal to the area of its base. In Fig. 1 let h = altitude of cylinder (valve lift) and r = radius of cylinder base (opening through valve seat). Then to meet the requirements of equal area

$$h \times 2\pi r \text{ must equal } \pi r^2$$

$$\text{and } h = \frac{\pi r^2}{2\pi r} = \frac{r}{2} = \frac{\text{diameter}}{4}$$

This merely expresses the generally accepted rule "valve lift equals ¼ diameter of valve opening."

In practice the valve is generally seated on a conical surface having an angle of 45 degrees, as you suggest. This surface is made as small as possible without unduly increasing the unit pressure exerted by the valve. On this account the above rule may be applied with substantial accuracy in practice, due allowance being made for obstructions in valve seat opening.

Uses of Specific Gravity

Q. (1162).—Of what uses to him are the specific gravity of the elements the marine engineer has to deal with? Give a simple rule, if any, for finding the weight, volume or specific gravity when only one or two of the three mentioned are known.

A. (1162).—Specific gravity of solids, liquids or gases, when known and used in conjunction with the weight of an

equal volume of water (for solids and liquids) and air (for gases) and the same temperature, determines the required unit weight of the substance in question. In other words, the two substances entering into the question must be at the same temperature and volume.

Example 1.—Required the weight of one gallon of fuel oil, the specific gravity of which is 0.9150. The weight of a gallon of water at 62 degrees F. (standard temperature) = 8.3356 pounds. Required weight = 0.9150 x 8.3356 = 7.627.

Example 2.—Required the specific gravity of fuel oil having a weight per gallon of 7.627 pounds at a temperature of 62 degrees F. As before with 8.3356 pounds as the weight of a gallon of water, we would have:

Specific gravity = 7.627 ÷ 8.3356 = 0.9150.

Example 3.—Required the volume of 10 pounds of fuel oil having a specific gravity of 0.9150 and a temperature of 62 degrees F.

$$\text{Volume} = \frac{10 \times 231}{0.9150 \times 8.3356} = 302.9 \text{ cubic inches.}$$

Where the volume of one gallon = 231 cubic inches, or basing on the weight of a cubic foot of water at 62 degrees F., which is 62.355 pounds,

$$\text{Volume} = \frac{10 \times 1728}{62.355 \times 0.9150} = 302.9 \text{ cubic inches.}$$

NEW BOOKS

Standard Seamanship for the Merchant Marine Service. By Captain Felix Riesenberg, C. E. Master Mariner in sail and steam. Size, 6 by 9 inches. Pages, 942. Profusely illustrated. New York, 1922: D. Van Nostrand Company.

This book is a very thorough work on the art of seamanship, covering not only the management of all types of vessels but giving a clear description and definitions of the different classes of ships, their construction and equipment. To present a book of this kind, an author must have a long practical experience on both sail and steam vessels. For this reason there are very few books on seamanship as compared with the works on navigation. The art has been passed along by word of mouth by those who have become expert in the knowledge of the sea by actual physical contact with its forces.

Captain Riesenberg, however, is a good seaman as well as an interesting writer and, still further, he acknowledges a long list of prominent marine men from whom he has drawn material for his work.

While the book will be interesting to anyone who likes the sea, it should be a great help to the ambitious sailor whether he be employed on the deck or in the engine room. One of the author's objects is to give the engine room force a clear idea of the management of a vessel and, at the same time, to give the man on deck a general knowledge of the engine room.

The principal value of this work lies in the opportunity it gives to the officer or sailor to use his spare time in perfecting his knowledge in the management of ships. When safety depends, as it does on shipboard, on incessant attention to manifold details, it is of the highest importance that those who have the ambition to command should have complete knowledge of their vessel and every piece of equipment on it. They should not only know but they should also have the ability to quickly apply their knowledge; for in times of emergency the question of safety or disaster often depends on instant action.

The diagrams and illustrations of equipment and fittings are particularly good and they should enable a quick grasp of the subject by the reader. Rules are given in a systematic manner covering the handling of a ship and the regulations required by the navigation laws. Ropes, block and tackle, stowage, boats, compasses, leads, logs, ground tackle, maintenance, weather and many other subjects are treated at length.

The Mathematics of Navigation

Reviewed by Charles E. Manierre

The Mathematics of Navigation. By Edward J. Willis, M. E. Size, 5⅜ by 8 inches. Pages, 38. Illustrations, 19. Richmond, Va., 1921: J. W. Fergusson and Sons.

This volume will interest those who are students of the science of navigation. It is also a book which astronomers will want in their libraries and which will appeal to engineers concerned with geodetic surveying. Much of its contents is quite new and cannot be found elsewhere. It has already received favorable comment from competent authorities in the United States and in all the large maritime countries of Europe; it has been approved as a reference book in Chinese nautical schools, and a German translation is now in process of publication and will soon appear on the list of Echardt & Messtroff, Hamburg.

The author has approached his subject by way of the calculus instead of by the usual methods of spherical geometry and trigonometry. This may account for his finding several new and useful equations. His position is that while it is necessary to work to five places of decimals to obtain an accurate position, it is only necessary to work to three places to correct an approximate position. His method for difference hour angle and difference latitude enables him to use a 20-inch slide rule as a substitute for much work now done by logarithmic tables.

As an example of the novelty of his methods, he describes a circle about the St. Hilaire assumed position, using difference altitude as a radius and locating the Sumner line as tangent to this circle and through a point determined as a difference longitude. Incidentally he develops a substantially new equation for the cotangent of the azimuth as an excellent substitute for the first and second of Napier's Analogies as used in Section 352 of Bowditch. It is true that Muir uses this equation in a somewhat different form for a different purpose though he did not develop it to this particularly useful result.

Mr. Willis has also found a rearrangement of the sin cos St. Hilaire problem in which the hour angle is the unknown quantity. This permits an excellent substitute for the usual chronometer error problem and for the long used sin cos longitude problem, and suggests a similar problem for the cosine of the azimuth, with altitude, declination and latitude as the known quantities. It is a form of equation which may be used in navigation and in other spherical trigonometry work for finding all unknown angles when three sides are given. There is also a new equation for cosine of the azimuth, particularly useful when the object is nearly east or west. Great circle sailing, the Mercator chart and a fix by simultaneous observations are all treated in a novel manner in a few pages which bring the book to its conclusion.

The propositions are clearly stated and the book is also unusual in its brevity. It is decidedly a case of quality and not quantity. The book will repay abundantly the study of those who nevertheless do not themselves contemplate making a change in their own form of working. On the other hand, anyone of sufficient mathematical training, who is in the habit of using daily the slide rule and Crelle's tables in solving other problems and who does not look with favor on logarithms, can adopt the method of the author with a minimum of effort.

PERSONAL MENTION

HUGH MACKENZIE, assistant general passenger agent of the Pacific Steamship Company since 1916, has been promoted to the newly created office of general passenger agent of this company.

J. J. EASON, formerly in charge of the repair department of the Shipping Board, is now associated with the Globe Marine Compositions Company, Inc., ship painters and manufacturers.

A. G. JACKSON has been transferred from the traffic department of the Shipping Board in Washington to take charge of Mediterranean and European affairs in New York, succeeding W. L. Bull.

REAR ADMIRAL J. D. BEURET, U. S. N., has been named by President Harding to succeed Rear Admiral D. W. Taylor, who recently resigned as chief constructor of the Navy. Admiral Beuret entered the service as a naval cadet in 1888 and graduated from the engineering division of the Navy in 1892. From October 1892 until December 1895 he studied at the Ecole des Mines and Ecole du Genie Maritime, Paris, and from this time until July, 1899, served as an assistant in the department of construction and repair at Mare Island Navy Yard. Leaving this post he became assistant to the superintending constructor at the Union Iron Works and remained here until July, 1901. For the next few years he held various posts in charge of the work of the bureau of construction and repair, becoming construction officer at the Navy Yard, Boston, in 1911. He held the position of inspector of hull material of the eastern district until May, 1913, following this with special duty in the department of justice. From December, 1914, until October, 1920, he was on the staff of the bureau of construction and repair and from then, until assuming his duties as chief of the bureau, was construction officer at the Mare Island Navy Yard.

Rear Admiral J. D. Beuret

HENRY J. MILLER was unanimously elected president of the Lake Torpedo Boat Company, Bridgeport, Conn., by the board of directors to fill the vacancy caused by the death of his brother, Herbert S. Miller.

W. L. BULL, head of the European and Mediterranean trades of the Emergency Fleet Corporation, has returned to the Mallory Transport Lines, having completed the special work undertaken for the Shipping Board.

GEORGE F. HILL has been appointed general agent of the North Atlantic and Western Steamship Company. Mr. Hill was formerly affiliated with the Erie Railroad at New York and later with the Norton Company of Worcester, Mass.

ANGUS MARSHALL, formerly general superintendent of the Alabama Dry Dock and Shipbuilding Company, Mobile, Ala., has resigned his position with this company to become vice-president and general manager of the Todd Shipbuilding and Dry Dock Company, Mobile, Ala. For 13 years prior to his association with the Alabama Dry Dock Company he acted as marine superintendent for the Texas Company and more recently as assistant manager of their shipbuilding plant at Bath, Me.

MEYER LISSNER, of Los Angeles, Cal., has been reappointed as a Pacific Coast representative of the Shipping Board. Mr. Lissner was born in San Francisco in 1871, received his education in the public schools at Oakland, Cal., and graduated from the Los Angeles Law School in 1899. Since 1899, until the new Shipping Board was formed last year, he was engaged in the practice of law in Los Angeles. In 1907, Mr. Lissner organized the Los Angeles City Club and was its president in 1911. He was president of the Good Government Organization and chairman of the First Board of Public Utilities in Los Angeles in 1909. He was also active in organizing the reform movement in California in 1910 and was chairman of the State Central Committee in that year. Mr. Lissner has always maintained an active interest in California's public service and was a delegate to the National Committees in 1912 and 1920. From 1914 to 1918 he was editor of the *California Outlook* and from 1916 to 1920 a member of the California Industrial Accident Commission. In 1921, on the formation of the new Shipping Board, he was appointed as a Pacific Coast representative.

Meyer Lissner

REAR ADMIRAL W. S. BENSON, U. S. N. (retired), former chairman of the United States Shipping Board, has been reappointed by President Harding as one of the Atlantic Coast representatives of the Shipping Board. Born in Bibb county, Georgia, in 1855, Rear Admiral Benson was graduated from the Naval Academy in 1877. In 1879 he was commissioned a midshipman and served on the *Constitution* for two years. In 1881 he was made an ensign and commissioned through succeeding grades to the rank of admiral (chief of naval operations), in 1916. Admiral Benson has served as commanding officer of several of the first class dreadnoughts and at one time was chief of staff of the Pacific fleet. From 1907 to 1908 he served as commandant at the Naval Academy and was commandant of the Philadelphia Navy Yard and supervisor of the third, fourth and fifth naval districts from August 1913 until April 1915, when he was assigned to duty as chief of naval operations. In the latter part of 1917, he was assigned to duty in London, after which he returned to the United States and remained until assigned to special duty in Paris. He remained abroad until June, 1919. In the following year, he was elected chairman of the Shipping Board for the unexpired term of John Barton

Rear Admiral W. S. Benson

Payne, who resigned to become Secretary of the Interior. Upon the formation of the new Shipping Board last year, Admiral Benson was appointed as a representative from the Atlantic Coast district.

W. L. Martignoni is representing Messrs. Pillsbury and Curtis, the naval architects of San Francisco, at the Sun Shipbuilding Company's yard where the passenger liner is being built for the Inter-Island Steam Navigation Company.

Captain W. A. Hindon has been made port captain of the United States Shipping Board, port of Boston, to relieve Captain John J. Coholon, resigned. During the war, Captain Hindon was on the staff of the commandant at the Hampton Roads Naval Base and also served as executive officer on several navy transports.

Arthur Stout has been made assistant to the general manager of the Todd Shipbuilding and Dry Dock Company's new plant at Mobile, Ala. Mr. Stout was formerly assistant general superintendent of the Alabama Dry Dock and Shipbuilding Company of Mobile and before this was with the United States Shipping Board, the Johnson Iron Works of New Orleans and the Marine Iron Works of Chicago.

Captain George F. Cooper, U. S. N. (retired), has joined the staff of Uttmarks Nautical Academy of New York and Boston. Captain Cooper will be in charge of the Boston school to relieve Captain L. Wessel. Captain Cooper had command of the U. S. S. *Louisiana* and was executive officer of the U. S. S. *Rhode Island* when these vessels were the "pride of the Navy." During the war, Captain Cooper was in command of several transports and later commandant of the eighth Naval District, the United States Naval Training Base and other activities at New Orleans.

Nathan A. Smyth, general counsel of the United States Shipping Board Emergency Fleet Corporation, recently resigned. Mr. Smyth joined the Emergency Fleet Corporation in July, 1921, intending to remain until January, 1922, but owing to the enormous amount of work on hand, decided to remain for another six months. Mr. Smyth was born in Quincy, Ill., but received his early education in New Haven, Conn. He graduated from Yale University in 1897 and from the Yale Law School in 1900. In 1901 he was admitted to the New York bar and has practiced in that state since that time. From 1902 to 1909 he was assistant district attorney of New York. During and immediately after the war he was assistant director general of the United States Employment Service Bureau, returning from this position to private practice. He was again called into the service of the Emergency Fleet Corporation as general counsel in 1921.

Joseph W. Powell, who recently resigned from the position of president of the United States Shipping Board, Emergency Fleet Corporation, has been elected a member of the board of governors of the Maritime Association, Boston Chamber of Commerce. Mr. Powell is generally regarded as one of the leading authorities of this country in shipbuilding and marine engineering. A graduate of the United States Naval Academy at Annapolis, Mr. Powell left the Navy after a few years' service to take up ship construction. He had charge of the Fore River Yard of the Bethlehem Shipbuilding Corporation and during the world war was elected vice-president of the corporation and organized and supervised all of the Bethlehem Corporation's shipbuilding operations. At the close of the war, Mr. Powell was called to Washington and accepted the position of president of the Shipping Board Emergency Fleet Corporation, serving in that executive capacity for a period of six months. Mr. Powell is deeply interested in the efforts being made to increase the business of the port of Boston and the other New England ports and as a member of the governing board will co-operate with the Maritime Association in its efforts to upbuild and increase New England's foreign trade through its own ports.

Sanford H. E. Freund, special counsel in charge of contracts, opinions, and recoveries of the United States Shipping Board has been appointed to succeed Nathan A. Smyth, general counsel for the Emergency Fleet Corporation, who recently resigned. Mr. Freund graduated from Harvard College in 1901 and from the Harvard Law School in 1903. Upon leaving the university, he became a member of the firm of Saltonstall, Dodge & Carter, attorneys at Boston where he remained until 1910, when he was appointed eastern attorney of the Chicago, Rock Island and Pacific Railroad Company. In 1912 he was chosen assistant general counsel for the Great Northern Railway Company and served in this capacity until 1918 when he entered the services of the Government as director of the clearance division, United States Employment Service. He left this position in 1919 to become assistant general counsel of the United States Railroad Administration, and later joined the legal staff of the Emergency Fleet Corporation.

OBITUARY

A. J. Frey, of Los Angeles, Cal., vice-president of the United States Shipping Board Emergency Fleet Corporation in charge of physical operations, died at the Johns Hopkins Hospital, Baltimore, Md., on June 13. Mr. Frey was one of the greatest ship operating organizers that the country has ever produced and Albert D. Lasker, chairman of the Shipping Board, when notified of his death, stated that the best work of the Board has been done in physical operations during the period that Mr. Frey was on active duty. For sixteen years prior to 1918 Mr. Frey was with the Pacific Mail Steamship Company, for the last eight years of which term he was assistant general manager. In May, 1918, he joined the United States Shipping Board Emergency Fleet Corporation at San Francisco and succeeded District Manager Pillsbury in charge of the ship construction division of the southern Pacific district. This position he held until July, 1920, when he entered the service of the Los Angeles Steamship Company as general manager. He resigned from this position in order to become associated with the Shipping Board. He was later made vice-president of the Emergency Fleet Corporation and continued in active charge of operations until he succumbed to the sickness which resulted in his death.

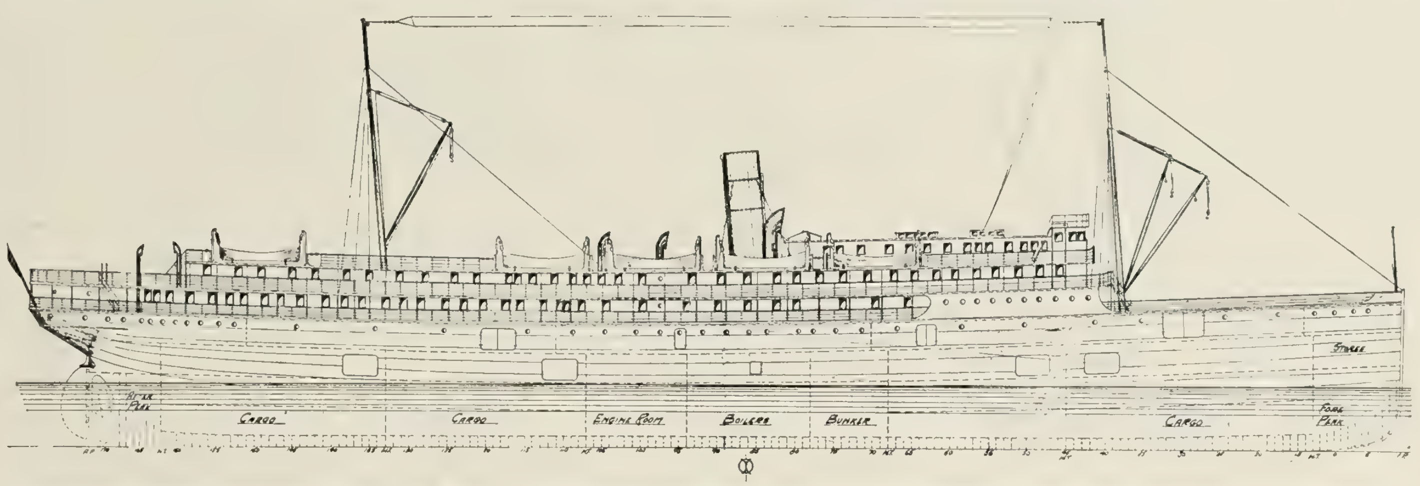
A. J. Frey

Herbert S. Miller, president of the Lake Torpedo Boat Company, Bridgeport, Conn., died recently at his home in Bridgeport.

Sir Ernest Manifold, Raeburn, K. B. E., who succeeded Sir Ashley Sparks as director general in this country of the British Ministry of Shipping, died in New York on June 1. His work here was the settlement of counter claims between the Shipping Board and the British Government as a result of the world war.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry



Outboard Profile Showing Type of Ship to be Contracted For By The Savannah Line For Atlantic Coast Service

Ocean Steamship Company, Savannah Line, Issues Plans and Specifications for Two Passenger and Freighters

Vessels Will Be Built of Steel, Driven by Reciprocating Engines Turning Single Screws—To Accommodate About 228 Passengers—Bids June 29

THE Ocean Steamship Company, of Savannah, E. R. Richardson, vice-president and general manager, Pier 35, North River, New York City, received bids for the construction and delivery of two steel, single screw combination freight and passenger steamships, until 12 o'clock noon (Daylight Saving Time), on June 29, to be opened at 3 P. M. on the same date. It is expected that the ships will cost approximately $1,000,000 each. The first ship is deliverable September 1, 1923, and the second ship, October 1, 1923. The vessels are to be similar in type to the company's steamers *City of St. Louis* and *City of Montgomery*.

DIMENSIONS

The specifications provide for a ship having an overall length of about 400 feet, length between perpendiculars 382 feet, beam molded 52 feet, depth molded to hurricane deck 35 feet, depth molded to main deck 27 feet, depth molded to lower deck 18 feet 6 inches, depth molded to orlop deck 10 feet 6 inches, load draft with 3,500 gross tons deadweight including cargo, coal, passengers, crew and stores, about 18 feet 6 inches. Maintained sea speed, loaded, not less than 12½ knots.

GENERAL DESCRIPTION

The vessel will be a steel hull, single screw, passenger and freight ship of the hurricane deck type, being schooner rigged with two steel pole masts. There will be a complete steel orlop deck in the cargo holds, steel upper between deck, steel main deck, steel hurricane deck, wood promenade deck and wood boat deck.

The propelling machinery will be an inverted, direct acting, triple expansion, surface condensing engine, having cylinders 26 inches, 43 inches and 72 inches diameter by 48-inch stroke with a working steam pressure of 200 pounds and the engine designed to develop 2,900 indicated horsepower at not exceeding 75 revolutions per minute. The air and two bilge pumps will be worked from the crosshead to the main engine, the other pumps to be independent.

BOILERS

There will be four, single-ended cylindrical return tube type main boilers, 14 feet 9 inches diameter by 11 feet 6 inches long, fitted for burning coal under natural draft. Diamond flue blowers and connections will be installed on all four main boilers.

CONDENSER

The condenser will be of the independent circular type. There will be about 4,100 square feet of cooling surface, the tubes to be of brass ¾-inch outside diameter by 17 BWG thick and the tube plates of rolled brass 1-inch thick. The propeller will be a right-hand true screw of about 16 feet diameter with cast iron hub and four manganese bronze blades.

ENGINE ROOM EQUIPMENT

The feed water heater will be of the Reilly multicoil type of sufficient size for heating the feed water to a minimum temperature of 200 degrees F. and two spare coils will be furnished.

(*Continued on page* 464)

Quarter Million Dollar Job Awarded To Dravo Co.

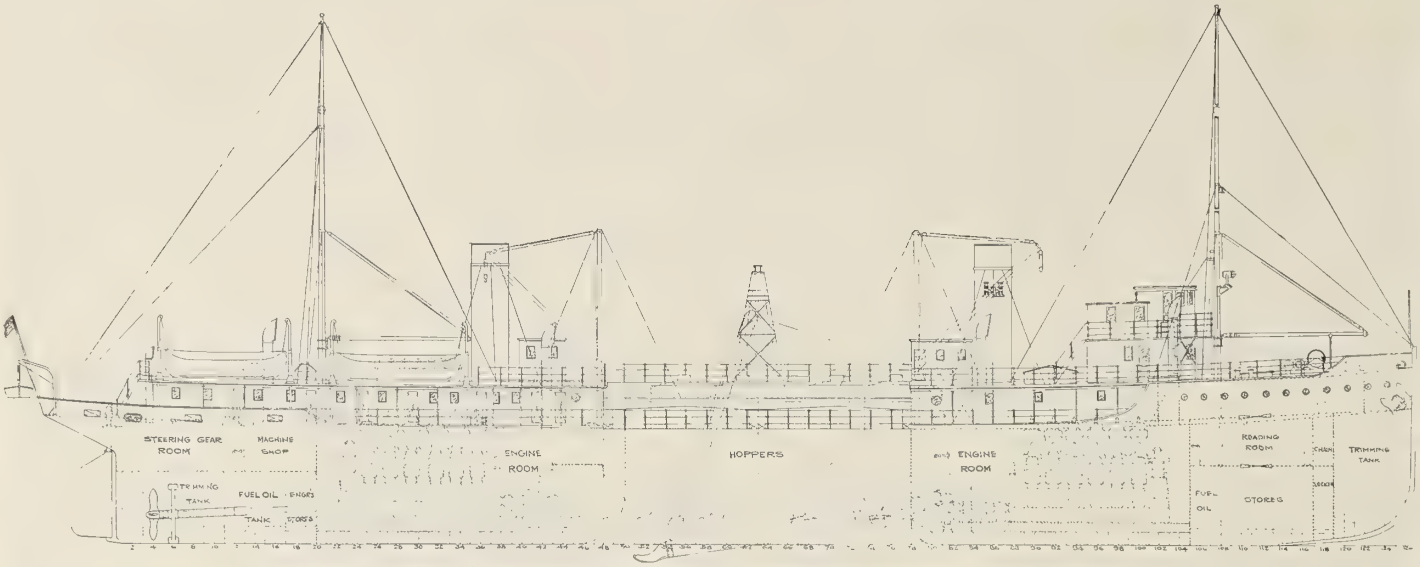
The Dravo Contracting Company has been awarded a contract by the Gulf Coast Lines, covering the design and construction of a new car transfer steamer, to be named *G. H. Walker*, at a cost of $250,000. The steamer will be constructed to handle complete train service between Mexico and the Southwest, and New Orleans and the East, across the Mississippi River, between Anchorage, La., and Baton Rouge, La.

The *G. H. Walker* will have a molded length of 340 feet, beam over guards of 90 feet, molded beam of 56 feet, depth of 11 feet, and will be of steel construction throughout. Complete trains will be handled by the boat at a single crossing. The Dravo Contracting Company plans to complete the boat on its Neville Island docks and send it South under its own steam, by way of the Ohio and Mississippi Rivers. It is intended to ship a cargo of 2,000 tons of steel products to New Orleans on her.

Two Stern Wheel Tugs Are Being Designed By New York Architects

PLANS and specifications are being prepared by Cox and Stevens, naval architects, New York, for a shallow draft stern wheel river towboat. The principal dimensions are: Length over all, 90 feet; beam, 20 feet and depth 4 feet. The propelling machinery consists of a 200-horsepower C. O. engine having a double roller chain drive and reduction gear. This boat is for the Kelley Axe Manufacturing Company of Charleston, W. Va.

A similar towboat, fitted with a 60-horsepower engine for the Peoria Grain and Barging Company of Springfield, Ill., is also being designed by Cox and Stevens. This boat is for service on the Illinois river.



Outboard Profile of Diesel-Electric Hopper Dredges to Be Built for Government

Three Million Dollars to Be Spent for Construction of Four Diesel-Electric Seagoing Dredges

War Department Issuing Plans and Specifications for 268-Foot Ships of Modern Design and Equipment—Will Have Capacity of 1,250 Cubic Yards—Bids Open August 2

The engineers of the war department, Washington, D. C., have prepared plans and specifications for the construction of four Diesel-electric, seagoing hopper dredges, each having a capacity of 1,250 cubic yards and which, it is expected, will have a total cost of approximately $3,000,000 to $3,250,000.

The specifications and plans will probably be in the hands of bidders by June 29 and the bids are to be opened August 2. The ships are to have an overall length of 268 feet 5 inches, length between perpendiculars 254 feet, beam molded 46 feet, depth 22 feet 6 inches, draft loaded 19 feet 6 inches, speed 11½ knots.

Propulsion

Each vessel will be equipped with three engines of the McIntosh & Seymour type of 1,000 brake horsepower on the four-cycle system. The engines will be direct-connected to 700 kilowatt generators for both propelling and dredging. They will produce a direct current of 500 volts. The two propulsion motors for the twin screws will develop 800 horsepower. They will run between 90 and 110 revolutions per minute on direct current and will be fully enclosed.

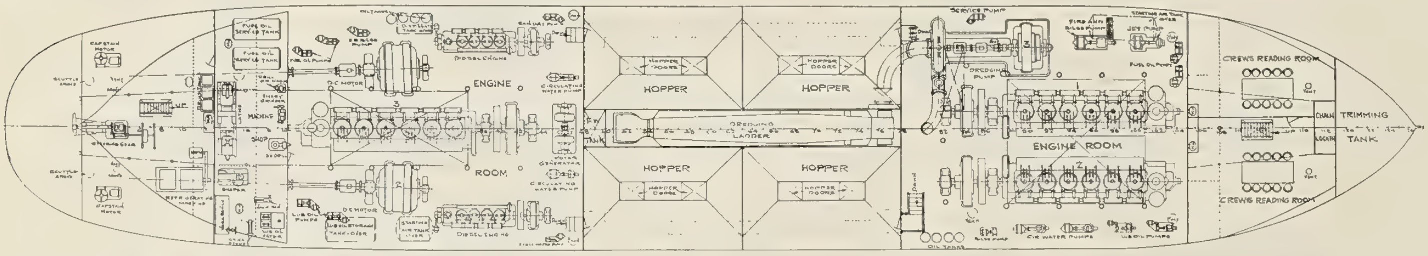
The dredging motor will develop 750 horsepower at 150 revolutions per minute and it will be directly connected to a 26-inch volute centrifugal, single suction, dredging pump.

Electric Control Throughout

The Ward-Leonard system of electric control will be installed so that the engines may be worked either from the pilot house or the engine room. It is thought that in actual use the engines will probably be controlled from the pilot house when dredging and in the engine room when the vessel is being navigated.

Approximate Cost

It is expected that the cost of these ships will range from approximately $750,000 to $800,000 each.



Hold Plan of Hopper Dredge Showing General Arrangement of Propelling Machinery and Auxiliaries

Ocean Steamship Company, Savannah, Issues Specifications

(*Continued from page* 463)

There will be two bilge pumps, 3 inches diameter by 21-inch stroke, one fitted at each side of the air pump. There will be two 2½-inch Metropolitan double-tube injectors and one auxiliary surface condenser consisting of not less than 450 square feet of cooling surface to be fitted with an independent, direct-acting, combined air and circulating pump. Steam pumps will include two feed pumps, 14 inches diameter steam cylinder, 9-inch diameter water cylinder, 24-inch stroke; two fire and bilge and ash ejector pumps, size 12 inches by 8½ inches by 12 inches, of the vertical duplex type; one ballast pump, size 7½ inches by 9 inches by 10 inches; one sanitary pump, size 12 inches by 8½ inches by 12 inches; one fresh water pump, size 6 inches by 6 inches by 6 inches and the main circulating pump will be of the centrifugal double suction type, 14-inch suction, driven by an independent, direct-acting, single cylinder engine, 8 inches diameter by 10-inch stroke. Two ash ejectors will be fitted in the fireroom, one on the port side and one on the starboard side.

There will also be one 4-ton service one one 4-ton spare refrigerating machine of the Brunswick or equal type on the ammonia brine system.

On the promenade deck there will be 40 rooms with 16 beds, 64 berths, accommodating a total of 80 passengers.

On the hurricane deck there will be 42 rooms with 4 beds, 80 berths, accommodating 84 passengers, making the total first-class passengers 164.

On the hurricane deck there will be 12 rooms with 24 berths, accommodating 24 passengers.

On the main deck there will be 8 rooms with 16 berths, accommodating 16 passengers, making the total number of second-class passengers 40.

Tenders Received For Three Freighters To Enter Coast Route

A REQUEST for bids for the construction of one, two and possibly three coastwise freighters for the Eastern Steamship Lines, Inc., of Boston, Mass., was recently sent to several shipyards on the east coast. The plans and specifications were prepared by Theodore E. Ferris, naval architect, 30 Church street, New York City, and bids were scheduled for opening on Wednesday, June 14. It is believed the ships will cost close to $300,000 each. They will be built of steel and driven by reciprocating engines turning a single screw.

Type and Dimensions

The ships will be of the hurricane shelter deck type having an overall length of 233 feet 3 inches; length between perpendiculars 221 feet 6 inches; beam molded, 38 feet; load draft, 17 feet; 1,400 deadweight tons and developing a speed of 11½ knots. The vessels will be schooner rigged having two steel pole masts with cargo derricks. There will be four hatches, four steel bulkheads and complete double bottom.

Propelling Machinery

The propelling machinery will consist of one triple expansion engine, 17 by 28½ by 48 by 36-inch stroke, developing 1,100 indicated horsepower, turning a single, four-bladed propeller at 98 revolutions per minute.

Boilers

Steam will be supplied by two oil burning, single ended Scotch boilers fitted with heated forced draft. The boilers will be of the two-furnace type, 11 feet 6 inches inside diameter, 11 feet long, having 2,972 square feet of heating surface and delivering steam at 190 pounds working pressure.

Engine Room

The engine room equipment will include one main condenser having 1,875 square feet of condensing surface, one main circulating pump of the centrifugal type with about 8-inch suction; one main air pump, one auxiliary feed pump, one fire, bilge and general service pump, one sanitary pump, one ballast pump, one fresh water pump, one scuttle butt circulating pump, one ice machine condenser circulator pump, two oil service pumps, one oil transfer pump, one feed water heater to handle 20,000 pounds of water and one 2-inch injector.

Plans and Specifications Out for Steel Freighter

Plans and specifications have been issued for the construction of a steel freight steamer for the Catskill Evening Line to run between New York and Hudson River points. It is understood that bids are to be received by J. W. Millard & Bro., naval architects of 17 State street, New York, who designed the vessel and drew the specifications, until July 15, 1922, decision on the contract to be reached probably by August 15.

The boat will be 192 feet extreme length, having a beam molded at deck of 40 feet 4 inches. She will be driven by a triple expansion reciprocating engine, steam being supplied at 180 pounds working pressure, by a coal burning single ended Scotch boiler.

$491,904 Is Low Tender for Construction of Twelve Sea Scows For New York Street Department

WITH a unit price of $40,992 and a total of $491,904 for 12 boats, W. H. Gahagain Company, of Brooklyn, N. Y., was low bidder for the construction of side dumper sea scows for the City of New York at the opening of bids by the Board of Purchase in Room 526, Municipal Building, Manhattan, on Monday, June 5. The bids submitted were as follows:

The specifications provide for a side dumper scow, length inside fenders 134 feet; breadth outside to outside of side planks 37 feet; depth molded to center, top of deck plank to bottom of bottom plank 14 feet; depth at sides, top of deck plank to bottom of bottom plank is 13 feet 8 inches; completely equipped for use by the Department of Street Cleaning.

	Unit Price	Total Price
W. H. Gahagain, Brooklyn	$40,992.00	$491,904
Atlantic Gulf & Pacific Co	44,491.67	533,900
Merchant Shipbuilding Corp.	49,000.00	588,000
Gildersleeve Shipbuilding Co.	60,000.00	180,000 (Total for three)

American Shipyards Building 208,310 Tons on June 1

Steel tonnage under construction and contracted for in the United States on June 1 this year totaled 122 vessels aggregating 208,310 tons, according to the American Bureau of Shipping.

Of this tonnage, the records of the bureau show, 20 ships of 155,205 tons are of the seagoing type and 102 vessels aggregating 53,105 tons are non-seagoing, including tugs, ferryboats, car floats, yachts, etc. This work is shown to be well scattered over practically all of the yards of the North Atlantic coast and the Great Lakes.

The bureau reports work contracted for and under way on June 1 as follows:

Yard.	Seagoing. Craft.	Seagoing. Tons.	Non-seagoing. Craft.	Non-seagoing. Tons.
American Bridge Co	..	......	19	5,950

Bids Asked for Construction of Steel Maneuver Boat Hull

Sealed proposals in duplicate for furnishing and delivering a steel maneuver boat hull for dam No. 1, Levisa Fork, of the Big Sand River, will be received at United States Engineer Office, Room 415, Custom House, Cincinnati, Ohio, until July 1, 1922, and at the United States Engineer Office, 1122½ Fourth avenue, Huntington, West Virginia, July 1, 1922, and thereafter until 10 A. M. (central standard time), July 10, 1922. Prospective bidders may obtain blue prints upon application.

Eight Hulls Building at Yard of Federal Shipbuilding Company

The Federal Shipbuilding Company, of Kearny, New Jersey, announces the moving of its general sales offices from 71 Broadway to 26 Beaver Street, New York City.

Contracts at the Federal yard at present include the following:

Hull No. 68—1 10,000 deadweight tonnage steel freight steamer, length 425 feet, beam 56 feet, depth 30 feet.

Hull Nos. 69-70—2 steel oil barges for Gulf Refining Company, length 158 feet, beam 37 feet, depth 11 feet 6½ inches.

Hull No. 71—1 steel drill boat for War Department, sub-contract from Dravo Contracting Company, length 157 feet, beam 52 feet, depth 12 feet 9 inches.

Hull Nos. 72-73—2 steel passenger and freight steamers for Merchants & Miners Transportation Company, length 350 feet, beam 52 feet, depth 27 feet 3 inches.

Hull Nos. 74-75—2 steel car floats for the Long Island Railroad, length 292 feet, beam 43 feet 8 inches, depth 11 feet 6 inches.

Military Ceremonies Mark Renaming of Madawaska to U. S. Grant

When the *Madawaska* was lowered from the 30,000-ton floating drydock at the plant of the Morse Dry Dock Company, Brooklyn, N. Y., June 3, General Grant's granddaughter, Princess Cantacuzens, Countess Speransky, renamed the vessel the *U. S. Grant.* The Secretary of War, John W. Weeks, the Assistant Secretary of the Navy, Colonel Theodore Roosevelt, General Robert E. Bullard and staff from Governor's Island, Colonel L. H. Pash, Colonel W. H. Hart and Colonel E. A. Simmons were among the officers who attended the ceremony. A company of infantry was also present and music was furnished by an army band. Colonel Pash acted as master of ceremonies.

The *Madawaska*, which has been reconditioned for the Army Transport Service, on the trans-Pacific run, is a vessel of 9,410 gross tons. She is 490 feet long, 45 feet beam and has a depth of 31.1 feet. She has been refitted with watertube boilers of the Babcock and Wilcox type and a complete new refrigeration system installed.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Repairs to Damaged Steamer, Portland.—The schooner Ecola recently went on a Portland drydock for repairs.

Freighter Cleaned and Painted.—The Sailer, freighter of Java Pacific Line, drydocked for cleaning and painting.

Steamer Construction, Baltimore, Md.—Weems-Williams Line, Baltimore, Maryland, to build combination passenger and cargo steamer.

Miscellaneous Repairs, Chester, Pa.—The Innoko, American steamship, was placed in drydock for miscellaneous repairs at Sun Shipbuilding Company, Chester, Pa.

Coast Guard Cutter Overhauled, Seattle, Wash.—U. S. coast guard cutter Arcata underwent general overhauling at Seattle, after which she returned to her station.

Norwegian Steamer Repaired, San Francisco, Calif.—Steamer Niels Nielsen, Norwegian vessel, after arriving at San Francisco from the Orient, was drydocked for repairs.

Motorship Drydocked, Seattle, Wash.—The motorship Kennecott, in the service of the Williams Steamship Company, went to Seattle, Wash., to be drydocked before loading at Tacoma.

Steamer Taken from Layup, Boston, Mass.—Boston floating hospital, laid up for winter at Charlestown bridge, was moved to Atlantic Works, East Boston, for scaling and painting.

Contract Award, Portland, Ore.—Lowest bid for repairs to Iowan, reported in collision with Welsh Prince, was $53,500, with no delivery time guaranteed; contract awarded on bid of $57,000.

Repairs to Steamer, Mobile, Ala.—The contract for repairs to the American steamer Nyanza, now at Pinto Island, was awarded to the Alabama Dry Dock Company, repairs to cost about $45,000.

Tanker Repairs, Chester, Pa.—Tanker J. W. Van Dyke, of Atlantic Refining Company, was drydocked at Chester, Pa., at Sun Shipbuilding Company's yards.

Miscellaneous Repairs, San Francisco, Cal.—Pacific Mail liner Golden State was awarded to Moore Shipbuilding Company, having submitted lowest bid.

Schoolship Drydocked.—United States steamship Newport, schoolship of the New York State Nautical School, was drydocked preparatory for its annual cruise.

Conversion to Suction Dredge, East Boston, Mass.—Extensive alterations to whaleback steamer Bay View, to convert to suction dredge, were made at Simpson's Drydock in East Boston. Vessel has been sold to Cleveland interests and will return to lakes.

Barge Launched, Hoquiam, Wash.—Largest lumber barge ever built on harbor at Hoquiam, Wash., was launched at Shilman Shipyard for fleet of W. R. Osborn, Aberdeen. It has capacity of 150,000 feet and fleet operated by Osborn can now handle 1,500,000 feet.

Conversion to Oil Burner, Mobile, Ala.—The Nika, wooden steamer purchased at Mobile by F. M. Stark, of San Francisco, converted to oil burner and placed in Pacific coastwise lumber trade. Mr. Stark is negotiating for purchase of another wooden ship for same business.

Repairs to Steamer, New Orleans, La.—Marine Iron Works was awarded contract for making necessary repairs to Swedish steamship Italia of New Orleans & South America Company. President Walker, of Marine Iron Works, superintended all general repairs and overhauling required.

Steamers Repaired, Newport News, Va.—Famous old James river steamers Brandon and Berkeley, for years operated between Norfolk and Richmond by Old Dominion Steamship Company and idle for last two years, have been sold to New York-Cape May Steamship Company. Boats to be repaired before going into service.

Construction Considered, New York.—Clyde Line has under serious consideration construction of two new cargo and passenger ships, service from New York to Charleston and Jacksonville. Vessels probably to be similar to company's steamship Lenape, about 425 feet long, driven by turbine engines, speed about 15 knots.

Vessel Conversion, Hoboken, N. J.—Standard Oil tanker Montrolite converted at Tietjen & Lang plant of Todd Shipyards Corporation, Hoboken, New Jersey, from a turbine to reciprocating engined ship. Steamship L. J. Drake of same company was also at the yard undergoing similar conversion. Estimated total cost for both, $100,000.

Ferryboat Launched, New York.—The ferryboat Poughkeepsie, for the Poughkeepsie-Highlands run, was launched Monday, May 29, from the ways of the Mill Basin Shipyard of the Atlantic, Gulf & Pacific Company, at Jamaica Bay. Her dimensions are: length, overall, 140 feet; beam, over guards, 52 feet; draft, at launching, 8 feet 3 inches; draft, loaded, 9 feet 6 inches.

Contracts Placed, Southern Yards.—United States steamship Johancy was sent to plant of Newport News Shipbuilding and Dry Dock Company; the Meanticut, to Warwick Machine Company; the Braddock, to Newport News Iron Works; the Hinckley, to Southern Shipyard; and Eastern Crown to the Newport News Shipbuilding and Dry Dock Company.

Twenty-seven Hulls Under Construction, Pittsburgh, Pa.—Twenty-seven hulls, having total of 5,477 gross tons, are under construction by Dravo Contracting Company, of Pittsburgh, Pa. List includes four steel sand and gravel barges of 320 tons each, three steel cargo barges of 215 tons each and four steel cargo barges of 135 tons each, awarded the company in April.

Motor Yacht Sold, New York.—Motor yacht Sachem was sold by A. M. Andrews, of New York, to Harry S. Leyman, of Cincinnati, Ohio. Vessel is a 90-footer and was fitted out at Tebo Yacht and Basin Company of Todd Shipyards Corporation. The transaction and incidental work were handled by Henry J. Gielow, Inc., naval architects and marine engineers of New York City.

Car Transfer Steamer Construction, Pittsburgh, Pa.—Dravo Contracting Company was awarded contract by Gulf Coast Lines, covering design and construction of new car transfer steamer, to be named G. H. Walker, at cost of $250,000. The vessel will have molded length of 340 feet, beam over guards of 90 feet, molded beam of 56 feet, depth of 11 feet, and of steel construction throughout.

Shipyard Activities, West Coast.—The Logan, army transport, was placed on Hunters Point drydock for general repairs, cleaning and painting; the Everett, of C. R. McCormick Company, went on Bethlehem ways; Dutch steamer Salaier was at Hunters Point; steam schooner Hartwood had her keel renewed, a new tailshaft and propeller installed, and Union oil tanker Los Angeles went on Bethlehem ways for general repairs.

Largest Diesel Yacht, New York.—The Diesel cruising yacht Dolphin, built by Newport News Shipbuilding & Dry Dock Company from designs of Cox & Stevens, New York naval architects, for Mortimer L. Schiff, was delivered to her owner on Saturday, June 3. Three months under construction. Claimed to be largest Diesel motor yacht built in this country, 180 feet long, 24 feet beam, 14 feet depth of hold, and equipped with two 500 horsepower Winton Diesel engines. Average speed 14½ knots.

Steamer Overhauled, Hoboken, N. J.—W. & A. Fletcher Company, Hoboken, N. J., was awarded contract for reconditioning steamship Philadelphia, formerly of the American Line and recently sold to New York and Naples Steamship Line. Reconditioning contract, including hull, engine and boiler work, involved expenditure close to $100,000. Transfer of vessel to new ownership and preparation for active service were under supervision of George G. Sharp, naval architect, engineer and marine surveyor, 30 Church street, New York City.

Japanese Fuel Ship Launched, Camden, N. J.—The Kamoi, launched on June 8 at yards of New York Shipbuilding Corporation, Camden, New Jersey, is a fuel supply ship ordered by the Imperial Japanese Navy. On length of about 500 feet and designed draft of 28 feet the vessel has a displacement of 20,000 tons and deadweight carrying capacity of about 13,000 tons. She is electrically propelled, designed to carry 10,000 tons of cargo oil and is expected to achieve 15 knots with 8,000 shaft horsepower. Boilers, special design and coal firing, provision made for oil burning.

SHIPYARDS AND DRY DOCKS

Steel Dry Dock Loose, New Orleans, La.—Steel drydock of Jahncke Shipyard Company broke loose from fastenings at Jahncke wharf and carried downstream with it the steamship Nyanza. Ten tugboats were still at work following morning opposite Port Chalmette. It was found the dock had become submerged, its base being fully thirty feet under water. It required combined efforts of crews of ten tugboats to pump the water out of various compartments of the dock before they towed it upstream.

PORT IMPROVEMENTS

Harbor Improvements, Canada.—Montreal is to receive a loan from the Canadian Government of $5,000,000 for construction of new terminal. Quebec is to spend $1,500,000, to be loaned by the city's harbor commissioners.

Grain Elevator, Owen Sound, Ont., Canada.—G. H. Thompson is interested in a syndicate which plans to build reinforced-concrete and steel grain elevator, 1,000,000 bushel capacity, on waterfront, $400,000. J. H. Tromanhauser, 69 Adelaide street, E., Toronto, engineer.

Additional Docks, Orange, Tex.—The Orange Wharf and Dock Commission employed architects to prepare plans and specifications for additional facilities to be constructed to the municipal docks under the $250,000 bond issue which was sold. Plans and specifications available shortly.

Contract Awarded.—McCaw, Tomlinson & MacDonald, Winnipeg, Manitoba, were awarded contract for dredging the intake and ship channel in the Niagara River, near Chippawa, by the Hydro Electric Power Commission of Ontario, 190 University avenue, Toronto, at price of $500,000.

Channel Improvements, New Jersey.—House passed bill authorizing appropriation of $2,150,000 for improving channel in Newark Bay and the Hackensack and Passaic rivers, and $10,400,000 for establishing a channel thirty feet deep and 400 feet wide through Raritan Bay, Arthur Kill and Kill von Kull, between New Jersey and Staten Island.

Harbor Improvements, Corpus Christi, Texas.—The Senate Commerce Committee have unanimously agreed to incorporate in the rivers and harbors bill a provision committing the Government to an ultimate expenditure of $1,394,000 for the construction of a deepwater harbor at Corpus Christi, Texas. The entire project calls for an expenditure of $5,000,000.

Sheds and Wharves to be Raised, New Orleans, La.—Millions will be expended in raising wharves and sheds at New Orleans to meet standard grade prescribed by United States War Department and Mississippi River Commission and concurred in by Louisiana State Board of Engineers. Work started on six sheds and wharves cost approximately $1,-000,000. After those are completed other sheds and wharves will be raised to standard grade.

New Bunkering Port, Houston, Tex.—Provisions for bunkering Shipping Board vessels at Houston were included in fuel oil contract recently entered into by Shipping Board and the Mexican Petroleum Company. The new acquisition is considered by operators as a marked advantage to the port, as it will enable Shipping Board vessels coming into Houston to lift cargo and take on bunkers at the same time. The bunkering will be handled for the Mexican Petroleum Company by the Houston Oil Terminal Company. The contract is effective until December 31 of the present year.

Dock to be Rebuilt, Norfolk, Va.—The entire south pier of the Merchants Transportation Company at foot of West Main street, Norfolk, Va., is being rebuilt. The work will be in progress during entire summer. The new pier is to be about 600 feet long and of frame construction with galvanized iron covering. New piles will be driven wherever necessary. Work is to be done by construction department of the company. This department is maintained for work on the many terminals at all ports served by the company. During reconstruction the north pier will be used for freight and passenger traffic. The exact cost of the work has not been determined.

GOVERNMENT WORK

Extension to Pier, Pensacola, Fla.—The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans extension to landing pier at Pensacola, Fla. Specification 4645.

Water Front Development, Pensacola, Fla.—Bureau of Yards and Docks, Navy Department, Washington, D. C., plans water front development at Pensacola, Fla. Specification 4644.

Contract Awarded, Providence, R. I.—J. S. Packard Dredging Company, 1004 Turks Head Building, Providence, R. I., was awarded the contract for dredging in harbor at Block Island, at price of $4,318, by the United States Engineer.

Dredging, Philadelphia, Pa.—The American Dredging Company, 410 Marine and Merchant Building, Philadelphia, Pa., has been awarded the contract for dredging on Liston Range, in Delaware River, 1,476,600 cubic yards excavation, at $0.18 per cubic yard scow measurement, by United States Engineer, 815 Witherspoon Building, Philadelphia, Pa.

NEW INCORPORATIONS

Castle-Lodge Steamship, New York, capital $125,-000, incorporated at Delaware.

Lodge Navigation Company, New York, capital $500,000, incorporated at Delaware.

Mandalay Steamship Corporation, capital $500,000, chartered under laws of Delaware.

The Fall River Steamship Company, capital $40,-000, chartered at Dover, Delaware.

China-America Line, filed application in Albany for increased capital from $150,000 to $1,000,000.

Phoenix Stevedoring & Trucking Corporation capital $100,000, incorporated at Dover, Delaware.

Phoenix Steamship Corporation, increased capitalization from $150,000 to $699,000, under the laws of Delaware.

Foreign Exploration Syndicate, of Manhattan, capital $100,000; incorporators, W. L. Crist, C. P. Stewart and E. Harding.

Ames Terminal Company, Washington, Delaware, capital $150,000, incorporated at Delaware to construct and operate terminals.

Franklin Lighterage Company, Manhattan, capital $5,000, incorporated at Albany; incorporators, J. van Pelt, J. McDonald and L. Kircher.

The Federal Stevedoring Company, capital $5,000 chartered at Albany; incorporators, S. & F. Barbarine and R. A. Flinn, of Manhattan.

The Navigation Steamship Company, Manhattan chartered at Albany for $250,000; incorporators, I. Olsen, M. E. Graef and L. W. Larslen, L. R. Bachner, attorney, 27 Cedar street.

The Northwestern Development Corporation, capital $1,500,000, to operate a steamship and transportation line between Portland and Seward, Alaska, headquarters to be at Vancouver, Washington; incorporators, A. J. Kaiser, L. C. Stringer and H. H. Dickson.

The New York-Naples Steamship Company, capital $250,000, organized under laws of Delaware; President, Mortimer B. Foster; George Ferguson, vice-president, and L. E. Schwartz, secretary and treasurer. Will handle operation of American Line ship purchased recently by United Italian Line.

Todd Shipbuilding and Dry Dock Company, Mobile, Alabama, capital $750,000, incorporated at Mobile; incorporators, William H. Todd, Arthur E. Goddard, John D. Riley, Dennis H. Lanman, of Brooklyn, New York, and Angus Marshall, Joseph H. Lyons and Harry T. Hartwell, of Mobile, Alabama.

Los Angeles General Steamship Agents, Los Angeles, Calif., incorporated recently and has taken over the agency of various steamship lines, including Struthers and Barry, Pacific-Argentine-Brazil, Swayne & Hoyt, Inc., Mexican States, Pacific-Caribbean-Gulf, Furness-Prince and Pacific Australian; incorporators, J. McMillan, C. G. Krueger and Walter Wheaton.

FOREIGN ACTIVITIES

New Motorship Ordered, Liverpool, England.—It is understood the Ocean Steamship Company, Liverpool, has ordered a 10,000-ton deadweight motor ship, about 400 feet long and to be delivered before end of 1922. She is to be equipped with a 3,000 indicated horsepower Burmeister and Wain long-stroke slow-speed Diesel engine, this being by far the largest motor of such a type yet built.

Engine Works Purchased, Glasgow, Scotland.—The shipbuilding firm of Swan, Hunter & Wigman, Richardson, Ltd., Wallsend-on-Tyne, has purchased the North British Diesel Engine Works at Glasgow, the best equipped plant in Britain for building large Diesel units. With the plant of their associated company, Barclay, Curle & Co., and their own plant at Walker, the firm now occupies a leading position as builders of oil engines.

Steamer Launched, Belfast, Ireland.—The passenger and mail steamer Diogenes of the Aberdeen Line has been launched from the new yard of Messrs. Harland & Wolff, Ltd. The launching of this ship was the first official ceremony at the new yard. The Diogenes is a sister ship of the Sophocles and is 500 feet long, 63 feet wide and 35 feet 3 inches deep, with a gross tonnage of 12,300 tons. She is for the owners' Australia trade.

Italian Fabricated Ships.—Six fabricated steel steamers are being built at yards of Cantiere Navale Triestino for Italian Cosalich Line. The fabricated steel was purchased in the United States from the Emergency Fleet Corporation. The first of the series, the Lucia has reached New York on her maiden voyage and is a ship of 8,610 deadweight tons, equipped to burn oil and driven by triple expansion engines of 2,300 horsepower, which give her a speed of 12 knots.

Engines for Steamships, Hamilton, Ohio.—Hooven, Owens, Rentschler Company, Hamilton, Ohio, closed contract with Federal Shipbuilding Company, Kearny, New Jersey, for furnishing two four-cylinder, triple expansion, 2,700 horsepower engines to be installed in new combination passenger and freight steamers which the shipbuilding company is building for Merchants' and Miners' Transportation Company, Baltimore, Maryland.

Four Ships, Great Lakes.—Recent contracts placed on the Great Lakes for new ships include two steel ore freighters to be built by American Shipbuilding Company of Cleveland for Pittsburgh Steamship Company; one steam freighter to be built by the Toledo Shipbuilding Company for the Kinsman Transit Company and one steel bulk freighter for the Franklin Steamship Company, of Cleveland, to be built by the American Shipbuilding Company. Vessels will be 600 feet long for cargo carrying, and propulsion will be by reciprocating engines.

Turpel Shipyard, Victoria, B. C.—It is reported that S. and E. Turpel, formerly connected with the Turpel Shipbuilding Yard and Marine Railway, at Victoria, B. C., are re-establishing the yard and marine railway on the old site, in the upper harbor. The original plant, absorbed by the Foundation Company during the war for building wooden steamships for British government under orders from the Imperial Munitions Board, had been in existence for about 35 years. The marine railway is said to be in course of construction and it is intended to operate a general ship repairing plant and to build small ships.

Trial Trip of Steamer, Belfast, Ireland.—The twin screw steamer Diomed, 10,180 tons, built by Messrs. Workman, Clark & Co., Ltd., Belfast, passed successful trials. The ship was constructed to order of Messrs. Alfred Holt & Company, Liverpool. Her dimensions are 489 feet by 62 feet by 30 feet. There are seven large cargo holds, the cargo gear being of the latest type, and the large number of winches and derricks are specially arranged for the expeditious handling of cargoes. The machinery was built by Messrs. Workman, Clark & Company, and consists of two sets of Brown-Curtis double reduction geared turbines, giving speed of 14½ knots.

Steamer Construction, Port Arthur, Ont.—The Port Arthur Shipbuilding Company, Port Arthur, Ont., has laid the keel of the steamship Mathewston. She will be a steel bulk freight steamship for Great Lakes service, for the Mathews Steamship Company, Toronto. The vessel will be 550 feet long, 58 feet wide and 31 feet deep, with a capacity for over 400,000 bushels of grain. Propelling machinery will consist of triple expansion engines, cylinders 25½, 41 and 67 inches diameter, by 42-inch stroke, supplied with steam by three Scotch boilers, each 13½ feet diameter by 11 feet 2 inches long, at 185 pounds working pressure, equipped with interchangeable furnaces. She is being built to the highest class for the Great Lakes, of the American Bureau of Shipping.

Motor Passenger Liner, England.—The Adda, large motor passenger liner under construction for the African service of Elder Dempster & Co., Ltd., was launched on May 25 from Harland and Wolff's Greenock yard. The ship's dimensions are as follows: length, 450 feet; breadth, 57 feet; molded depth to awning deck, 34 feet 6 inches. Her gross tonnage is about 7,800. There will be three complete decks. Passenger accommodations will be very spacious and luxuriously furnished. Berths are to be provided for 225 first, 74 second, and 32 third-class passengers. Propelling machinery will consist of two Burmeister and Wain type engines built by Harland & Wolff at Glasgow. They will each develop 3,000 indicated horsepower at 115 revolutions per minute.

Three New Motorship Contracts, Denmark.—An order has been placed by the Svendborg Shipping Company for a single-screw motorship, which will be one of the largest of its type equipped with Burmeister and Wain machinery. It is to be constructed at the Odense Shipyard, Denmark, and will have deadweight capacity of 5,100 tons. The new vessel will have the following dimensions: length between perpendiculars, 331 feet 3¾ inches; breadth, molded, 44 feet; depth from the shelter deck, 28 feet 11 inches. She will be of the open shelter-deck type and will have a speed of 10½ knots when fully laden. The same company has also ordered from the Odense yard two 7,770-ton deadweight, twin-screw motorships with a length of 378 feet 2 inches each, and the machinery will be constructed by Burmeister and Wain, Copenhagen.

Diesel Motorship, Copenhagen.—May 6, a new Diesel motorship was launched at the Copenhagen yard of Burmeister & Wain and was named Thalatta. She is being built for the Norwegian African & Australian Line, Tensberg, Norway. The ship is a sister vessel to the M. S. Teneriffa, which was recently delivered to the Mexican Gulf Line. The Thalatta is built to highest class of British Lloyds and intended for ordinary cargo-carrying trade, the main dimensions being 425 feet 5½ inches by 55 feet by 38 feet 6 inches, and her deadweight capacity being about 11,000 tons. The ship is being fitted with two Burmeister & Wain Diesel engines, developing in total 3,100 indicated horsepower and capable of giving the loaded ship a speed of 11¼ knots. The fuel oil consumption for 24 hours is about 10 tons. Cooling plants for the stores and a few but especially well equipped passenger rooms are arranged.

STEAMSHIP INTERESTS

The Admiral Line has made a slash of 50 percent in charges for carrying automobiles, as a move to stimulate tourist traffic between points on California, Oregon, Washington and British Columbia coasts. The line is now operating five passenger and freight steamers between Puget Sound and Californian points and two between Portland and California. Under the new rates, automobiles are handled under the baggage service.

The New York & Porto Rico Steamship Line has reduced its passenger fares between New York and ports of Porto Rico. The company's sixteen-day cruise around the island, which for years has been a popular vacation feature, is reduced from $180 to $150 for minimum accommodations and the one-way fare from New York to San Juan is now $65 instead of $75. These reductions are permanent.

The Luckenbach Steamship Company inaugurated from San Francisco, with the sailing of the freighter *Pleiades,* a monthly service in the Pacific Coast-Gulf service. The company is now operating four vessels in the service.

Owing to a prospect of good business in the fall, the Furness-Prince Line proposes to resume its Pacific coast European service in August or September. The Furness-Prince Line boats have been going to the Far East for several months.

The Atlantic Fruit Company has cut its passenger rate from New York to Porto Rico. The fares have been reduced approximately 20 percent with the former minimum of $75 reduced to $60. The Atlantic Fruit Company operates a weekly service to San Juan, Ponce, Mayagues, Arecibo and Aguadilla.

TRADE PUBLICATIONS

MICARTA GEARS AND PINIONS.—To fill the demand for a silent gear drive the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., has developed a non-metallic gear material known as Micarta which is described in a recent catalogue issued by this company. General technical data on the cutting of gears from this material are contained in the bulletin, as well as tables of pitch, tooth thickness, horsepower ratings, etc.

MERCHANT SHIP AUXILIARIES.—A bulletin containing engineering data pertaining to marine motors and controllers for engine room auxiliaries and deck machinery has been issued by the General Electric Company, Schenectady, N. Y. Concise information is given on horsepower, voltage, speed, weight and approximate dimensions of standard type marine motors; and special attention devoted to the question of lubrication, moisture proof windings, non corrodible fittings, water tightness, etc. The cost of equipment is not given in the bulletin because of the fluctuating condition of the market, but will be supplied from the company's offices.

VELOCITY STAGE TURBINES.—A line of velocity stage turbines, especially designed for high pressure and high temperature steam is described in a catalogue issued by the DeLaval Steam Turbine Company, Trenton, N. J. The turbines are built in sizes up to 1,200 horsepower and are designed to be directly coupled to high speed centrifugal pumps and blowers, small alternating and direct current generators, and by means of double helical speed reducing gears to large pumps and blowers, medium size generators, belt pulleys, rope sheaves and slow and moderate speed machinery.

BUSINESS NOTES

Mr. Adolph Starr, who for four years was associated with The Superheater Company in their marine sales and service division, has severed his connection with that company and has taken up the duties of Assistant Sales Manager for the Seminole Chemical Company, dealers in boiler cleaner, at 75 Vesey street, New York City. Mr. Starr, who has spent a great many years in various branches of the marine industry, is receiving the well wishes of a large number of friends in the marine field.

Mr. L. D. Howell, formerly of the marine department of the Westinghouse Electric & Manufacturing Company, at East Pittsburgh, Pa., is now attached to the marine division at the New York office of the same company in association with Mr. Norris R. Sibley.

The American Bridge Company announces the location of the Vice President's Department, Chief Engineer's Department, Eastern Division Contracting Department and Treasury Department, in the Empire building, 71 Broadway, New York, N. Y. (telephone, Whitehall 3290), which became effective on June 24.

The American Abrasive Metals Company of 50 Church street, New York City, the manufacturers of feralun, alumalun, vulcalun and bronzalun anti slip treads announce their appointment by the Carborundum Company of Niagara Falls to act as United States sales representatives through whom will be marketed the carborundum anti slip tile.

The Titan Iron and Steel Company, Inc., Newark, N. J., manufacturing mechanically puddled wrought iron, has announced the appointment of W. Woodward Williams as vice-president.

The Lake Torpedo Boat Company, of Bridgeport, Conn., announced that at a meeting of the Board of Directors on May 12, Henry J. Miller was unanimously elected president of the company to fill the vacancy caused by the death of his brother, Herbert S. Miller.

WE GUARANTEE that of this issue, 5,800 copies were printed; that of these copies 4,198 were mailed to regular paid subscribers, 129 were provided for counter and news company sales, 231 were mailed to advertisers, 29 were mailed to employees and correspondents and 1,213 were provideed for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 44,250—an average of 5,531 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

In the Laps of the Gods

AT this writing the fate of the shipping bill and, incidentally, our merchant marine, lies in the balance. Senator Joseph E. Ransdell, democrat of Louisiana, has just delivered a stirring speech in the Senate in which he showed the bitterness of organized foreign opposition to the pending bill. Many would have us believe that the opposition to the proposed subsidy comes from the Middle West but, if this is true, how does it happen that the Mississippi Valley Association, embracing a membership in 28 states, should address Senator Ransdell, declaring that "proof is now conclusive that the powerful shipping interests of England are determined, if possible, to prevent the enactment of the ship subsidy bill?"

The Mississippi Valley Association, at least, is tired of having the responsibility for the apathy or lack of action by Congress placed upon the Middle West. President Harding evidently entertains the same point of view, for he has made it plain that the bill should pass during this session and that the whole country is behind it. In other words, the "defeatist" propaganda whether started by foreign interests or, as is more likely the case, by Americans employed by foreign interests, should delude no one into the belief that America is not determined to pass this bill the provisions of which are so vital to our merchant marine.

Following Senator Ransdell's speech, President Harding let it be known that he is still determined that the ship subsidy bill shall be passed during the present session of Congress. It must be remembered that he only agreed to a postponement of action on the measure on condition that it would be taken up again before the summer was over. It is therefore our prediction that he will demand that the House shall take this matter up immediately after reconvening on August 15.

The same feeling of uncertainty existed in regard to the reconditioning of the *Leviathan* for a couple of months before the contract was signed. Chairman Lasker of the Shipping Board, however, constantly declared that this great ship would be refitted for service and, just as he was right in his judgment then, so he is now in regard to the shipping bill. He has full confidence that the bill will be passed at this session and he is not allowing himself to be worried over reports that the Senate leaders are trying to eliminate the subsidy legislation from their program.

Chairman Lasker knows that the shipping bill was prepared from the facts and findings of the most competent committees of marine experts ever gotten together in this country. He has had the most exhaustive studies made on the subject as the twenty-five hundred and odd pages of the recent testimony taken before the joint hearings of the Committee of Commerce and the Committee on the Merchant Marine and Fisheries will show. He knows that he is right in advocating ships built and manned by Americans for commercial purposes and for safety in time of war. But of still more importance he knows that the opposition has no arguments that will hold water and that its only hope of defeating the shipping bill is to delay action. This it cannot do unless the country has reached the zenith of its destiny and has started downward.

Economical Fuel Consumption

ONE of the greatest single steps taken by the Shipping Board to secure maximum economy in ship operation has just been started by Mr. Joseph E. Sheedy, acting vice-president of the Emergency Fleet Corporation. Mr. Sheedy has organized a committee under the chairmanship of Captain C. A. McAllister to study the proper basic fuel consumption of Shipping Board vessels, to review present fireroom practices and burning equipment and to recommend improvements in each.

Under present conditions it is absolutely imperative to reduce the cost of ship operation to a minimum and no single item of the operating costs amounts to as much as the fuel bill. MARINE ENGINEERING AND SHIPPING AGE has re-

peatedly hammered this point for a great many years particularly in the articles written by "Old Scotch." We therefore feel that we have had some influence in creating this committee whose work will undoubtedly be of great value to private shipowners as well as to the Shipping Board.

Senator Marconi Receives Highest Engineering Honor

THE John Fritz medal, America's highest engineering honor, was awarded to Senator Guglielmo Marconi in the auditorium of the Engineering Societies Building on Thursday, July 6. This medal, which is of gold, is awarded not oftener than once a year. It is accompanied by a certificate stating the origin of the medal, the specific achievement for which it is awarded and bearing the signatures of the sixteen members of the board making the award. The board is composed of four representatives from each of the four National Societies of Civil, Mechanical, Mining and Electrical Engineers.

It should be particularly gratifying to the marine profession that the award this year has been made to Senator Marconi. His invention, which was almost immediately applied to ships, has taken from the sea many of its perils and even when disaster has occurred it has been the means of saving large numbers of human lives. In the case of the *Titanic* disaster alone, it is not probable that a single soul would have been rescued, if it had not been for the wireless telegraph.

Radio has made it possible for ships at sea to give their location and condition to the shore and to other vessels; it has made it possible, through triangulation, for shore stations to inform a ship of its exact position and its proximity to dangerous shoals when fog or bad weather conditions prevent the taking of observations; it has made it possible to warn ships of approaching storms, and for them to keep in continuous communication with the entire world. Certainly no one has done more or has been of more benefit to those who live and travel the seas than Senator Marconi.

Cadet Engineers

THE White Star Line is finding it profitable to give engineering students from the Liverpool University a position on their liners during the summer vacation. This scheme, which was inaugurated by Mr. Willet Bruce, the company's superintending engineer, was started last summer and provides a position for an engineering student on each liner leaving Liverpool between July 1 and October 5.

The students either take watches with the regular engineers or are given duties connected with the running of the auxiliaries and the overhaul of deck machinery. The practical experience that they get in this way could not possibly be obtained on shore and those students who seize the opportunity ought upon graduation to have a far better chance of securing a desirable position with a steamship company.

On the other hand the steamship line that gives such an opportunity to engineering students not only secures enthusiastic workers for practically nothing but it also has the chance of picking the most efficient men for future employees. All American lines whose engineering staffs ashore and afloat are not 100 percent efficient might give some thought to such a scheme. Henry Ford has the same idea only in his characteristic big way he has established a school for 600 boys who are given practical training in his shop. The results of these instances of combined theoretical and practical training are for the future to disclose but, if Henry Ford and the White Star Line think it advisable to train their future personnel, other companies might do worse than follow their example.

Simplification and Standardization

DUE to the fact that ships are usually built one or two at a time and then to meet the particular requirements of a specific trade and route, an opportunity to take advantage of the savings that can be accomplished by quantity production of standardized vessels such as were built during the war will never be repeated.

However, there is an opportunity to do much in the way of standardization and simplification in the fittings and equipment that go into a ship. The Navy Department and several shipyards have developed a number of standards for which, in a great many cases, expensive dies, patterns and jigs have been made. The standards of one yard vary to a greater or lesser degree with the standards of another yard and, on account of the above-mentioned expensive dies and patterns, to say nothing of the personal opinions of the chief engineers of the various shipyards, it will be a difficult matter to interest the shipbuilding fraternity in harmonizing these standards and making them universal.

England, however, which is considered more conservative than this country and whose shipyards are much older than ours, is doing this very thing. The British Engineering Standards' Association has appointed committees consisting of men of the highest authority in their respective lines who have met at frequent intervals and examined drawings and sketches of proposed standards.

Not only have they done this, but they have also adopted a large number of standards during the past few years which have eliminated the manufacture of an unnecessarily great number of articles serving one purpose. This has been of substantial benefit to the shipbuilding industry in that country as a whole as it has prevented overlapping, and it is in line with the principle of industrial standardization that has been practiced successfully in other industries.

Mr. Herbert C. Hoover states in an article that appears on page 481 of this issue that the avoidance of waste in the industries is more important than great inventions. He has established in the Department of Commerce a Division of Simplified Practice which stands ready to cooperate and assist the industries to bring together representatives from all interested bodies in any industry for the purpose of effecting standardization and simplification. Is it not a worthy subject for the Society of Naval Architects and Marine Engineers, the American Engineering Standards Committee, the American Bureau of Shipping, the shipowners and shipbuilders to take up with the Department of Commerce in order that the cost of construction of ships between this and foreign countries may be decreased rather than increased?

Plans for American Marine Week Far-Reaching

To Be Great Convention of All Associations Interested in Developing a Real American Merchant Marine

THE big shipping event of the year, American Marine Week, November 4-11, with its Marine Exposition at the Grand Central Palace, New York City, with its convention of the Society of Naval Architects and Marine Engineers, with the meetings of the technical committees of the American Steamship Owners' Association and the American Bureau of Shipping, and with its banquets and smokers, will be the greatest get-together of the various interests in the marine field that this country has ever seen.

It is the primary purpose of American Marine Week to attract the attention of the whole country to our merchant marine. Shipping legislation is now pending before Congress which is of vital importance, not only to shipping, but also to the prosperity of every other industry. Therefore, this is a time when the cooperative efforts of all marine associations can be used to the best advantage.

American Steamship Owners' Association

Mr. Winthrop L. Marvin, vice president and general manager of the American Steamship Owners' Association, in speaking of the forthcoming event, said, "I believe that this movement is in every way deserving of the heartiest encouragement and I expect that the American Steamship Owners' Association will participate to an even greater extent than they did last year."

At the conclusion of the last American Marine Week, Mr. Marvin made the following statement in a letter to the editor of Marine Engineering and Shipping Age: "It is unquestionably the wisest and best plan to hold the annual marine exposition at the same time with the annual convention of the Society of Naval Architects and Marine Engineers. The exposition this year has been remarkably satisfactory from the standpoint of the shipping trade. Exhibits were well considered and skilfully arranged and they strongly appealed to the serious attention of the practical men of our maritime industries. We heartily felicitate the management of the exposition on the valuable results attained."

Society of Naval Architects and Marine Engineers

The annual convention of the Society of Naval Architects and Marine Engineers always has been an important occasion to the leading technical men in the marine profession. It is at these conventions that papers covering the developments in shipbuilding and marine engineering are read and discussed and there is no doubt that these meetings have been of tremendous benefit to the industry as a whole. In commenting on the desirability of holding the annual marine exposition at the same time, Mr. E. H. Rigg, naval architect, New York Shipbuilding Corporation, said last year: "The exposition unquestionably gave an opportunity to those directly interested in maritime affairs, as well as to the general public, whose interest in maritime affairs is undoubtedly much greater than before the war, to see a very full line of maritime equipment and fittings assembled under one roof and in such a way as to be both useful and interesting." There were many in New York for the purpose of attending one or the other of the concurrent meetings, so that advantages should have accrued to each participating organization.

In like manner, Mr. Hugo P. Frear, naval architect of the Bethlehem Shipbuilding Corporation, Limited, in speaking of the last American Marine Week gave his opinion that "the idea of holding the show in conjunction with the meetings of the Society of Naval Architects and Marine Engineers appeals to me and I think this arrangement should be continued so long as there appears to be an advantage in the combination."

American Bureau of Shipping

The American Bureau of Shipping will take part in the forthcoming American Marine Week by holding meetings of their board of managers and their technical committees. The bureau is the only American organization of its kind in this country and it is the official classification society for United States Government-owned ships. It can always be depended upon to support any movement that will aid in the development of an American merchant marine.

Maritime Association

The Maritime Association of the Port of New York, whose fiftieth anniversary will occur next winter, has been invited to participate. Mr. Charles H. Potter, president of that association, when interviewed by a representative of Marine Engineering and Shipping Age, declared himself as heartily in favor of the movement. He said that he would recommend participation by his organization at their next meeting.

The Sea-Going Engineers

The Ocean Association of Engineers will hold a big smoker during American Marine Week and they will see that every engineer on every ship in the Port of New York at the time is furnished with tickets admitting them to the marine exposition. Mr. Bert L. Todd, secretary of the association, declared "that he believed that American Marine Week will be a means of interesting the people in an American merchant marine and that it was deserving of support from all organizations connected with shipping."

The Masters and Mates

Capt. John F. Milliken, secretary-treasurer of the Neptune Association, which is composed of the licensed masters and mates of ocean and coastwise steam vessels, and also secretary-treaurer of the Ocean Officers' Conference, which includes the licensed deck and engine room officers and the radio telegraphers, declared that the Neptune Association would hold a big smoker during the week and that probably this smoker would be held in conjunction with the marine engineers. During the week the Ocean Officers' Conference will hold a meeting of its executive committee and officers.

Captain Milliken hopes that there will be an opportunity during American Marine Week for delegates from all marine associations to get together in a special meeting for the purpose of discussing our merchant marine problems and he believes that such a meeting would undoubtedly result in some very valuable suggestions.

National Merchant Marine Association

The National Merchant Marine Association, through its secretary, Henry C. Wiltbank, has notified the American Marine Association that its executive committee is in favor of cooperating in the event and that it will be glad to arrange the details for its participation.

American Marine Association

Steps are now being taken to complete final arrangements of the Second Annual Marine Exposition, to be held under

the auspices of the American Marine Association, Inc., November 4-11, 1922, at the Grand Central Palace, New York City. The various committees of the association are now actively undertaking the duties assigned to them, in order to assure a most successful gathering of the marine interests. Already space reservations for the November exposition presage an interesting and ambitious presentation of the varied phases of shipping activity, embracing shipbuilding and its allied branches, ship operation and the extensive group of supply organizations.

K. W. Heinrich to Direct Marine Association

In order properly to co-ordinate committee activities, the American Marine Association, Inc., has prevailed upon Mr. K. W. Heinrich, who has been identified with the Bethlehem Shipbuilding Corporation, Ltd., to accept the management and direction of the association. In this capacity, Mr. Heinrich will execute the recommendations of the various committees looking after all details in connection with the exposition and association affairs. It is certain that the cooperation of other marine organizations will be secured to such a degree, that the November Marine Exposition is certain to command national attention, both from its business aspects, as well as the influence it will exert in furthering the interests of an American merchant marine. Mr. Heinrich has had broad experience in exposition development as a result of his work with the Bethlehem Shipbuilding Corporation, Ltd., and this experience, in conjunction with his extensive knowledge of maritime affairs, is expected to give to the American Marine Association many benefits of direct contact with the industry and its allied ramifications.

Exhibit Space Reservations

The exhibits committee of the association has about completed its preliminary work and over the next few months it is confidently expected that definite space reservations will be had for the majority of the organizations that participated in the previous exposition, as well as many others who hitherto have not exhibited their products.

The membership committee has been industriously soliciting support from marine concerns, who are not in a position to exhibit, but who are contributing their moral support to the successful consummation of the aims of the association.

Shipbuilders to Be Represented

In an interview with J. L. Ackerson, president of the Atlantic Coast Shipbuilders' Association, a representative of Marine Engineering and Shipping Age has learned that the Atlantic Coast Shipbuilders' Association will be represented at the Marine Exposition by an official committee. Furthermore, this association will help in other ways to make the Exposition and Marine Week an unqualified success in every way. The Atlantic Coast Shipbuilders' Association is the leading organization in the American shipbuilding industry and is the active medium through which shipbuilders seek to secure united action on shipbuilding problems.

Steamship Kutsang on Her Trial Trip

The Indo-China Steam Navigation Company has just increased its fleet by the addition of the *Kutsang* built at the Wallsend Shipyard of Swan, Hunter & Wigham Richardson, Limited. The ship's name is Chinese and signifies "Increase in Luck." In spite of somewhat boisterous weather, the trials at sea were successfully accomplished and a speed of 13.6 knots on a draft of 23½ feet was averaged over a course of 40 knots along the coast off the mouth of the River Tyne. The *Kutsang* has an overall length of 434 feet, a beam of 54 feet and a depth of 31 feet. She carries 7,800 tons deadweight on a draft of 26 feet 3 inches, and has been built to Lloyds highest class. On the bridge deck are quarters for the officers and engineers together with commodious staterooms and a handsome dining saloon for first class passengers. On the boat deck is accommodation for the captain and for first class passengers, smoking room and ladies' room. Second class passengers are accommodated in the poop, and a hospital and dispensary are placed above the steering gear house.

Ship Subsidy Bill Stands on Its Own Merits

Educational Campaign Shows Basic Facts Underlying the Bill Irrefutable—Forms Keynote of Policy of Present Administration

By "Old Scotch"

"BOOZE" has been a trouble-maker ever since mankind has made use of it for purposes of exhilaration and to chase away gloom. Just as the stage was set for consideration of the subsidy bill, along comes a famous temperance advocate, a (per force of circumstances) reformed brewer, who spills the beans and starts a general alarm throughout the land because of his discovery that booze was being sold on board passenger ships operated by the Shipping Board. Without knowing anything about the motives which impelled this "nouveau" temperance advocate to jump in the breach at this critical time, it looks to a bystander very much as if there existed in his bosom a sentiment such as "If we can't make it on shore, we'll see that no one sells it on the ocean."

Sale of Liquor on American Ships Never a Secret

Everyone at all cognizant of maritime affairs knew full well that American ships, by competent legal authority, were "wet" beyond the three-mile limit. Nothing was done officially to suppress this fact from the public and anyone having the slightest interest in the matter would have been advised that such was the case. A former United States senator, who was one of the wheelhorses of the prohibition movement, made the announcement in the open Senate in January last, that he had recently returned from London on a Shipping Board vessel and that he saw liquor being sold on that ship. No one expressed any surprise, nor did the press make any more than passing comment on his statement. Yet when this ex-brewer made the same kind of a statement last month, the opponents of the subsidy bill seized the opportunity to raise a hullabaloo which was heard all over the world.

The net result of this re-vivified exposé has been the postponement of the consideration of the bill until August 15, when the House of Representatives reconvenes. This, after all is said and done, is probably a blessing in disguise. It will give Congressmen, who themselves were none too familiar with the subject, a chance to study the subject and take counsel with their constituents as to how they should vote when the bill comes before them. Hence the period from July 1 to August 15 will undoubtedly be occupied to a considerable extent by discussions on the value of a merchant marine to the country at large.

Shipping Legislation the Keynote of Present Administration

The administration officials in Washington are so firmly convinced of the righteousness of the cause that the merchant marine legislation has been made the keynote of the announced policy of the present Government. Whatever the great voting public may think of the actions of the present Congress, or rather the lack of action, there is on all sides a firm conviction that the executive branch of the Government has accomplished much for the benefit of the country, despite legislative shortcomings. Hence it should be realized by congressional candidates for re-election that they themselves are on trial before the bar of public approval, and not the officials of the executive branch of the Government.

The public has strong faith in President Harding's policies and motives, and they undoubtedly give him credit for knowing the conditions which have impelled him to stake the reputation of his entire administration on the success or failure of the pending merchant marine legislation. They know that he is a man from an interior state, a representative of that great middle west which we all speak of with so much veneration as reflecting the last thoughts and actions of the entire country. They know that neither he nor his immediate surroundings have financial interest in the rise or fall of our shipping. He and his co-laborers in this cause have approached the entire shipping subject on the broadest of patriotic grounds, and with a vision that calls for the unstinted approval of all thinking Americans who can look beyond the immediate present and realize how helpless this nation will be in the years to come, if we do not seize this present opportunity and firmly establish an efficient merchant marine to stabilize our commerce in times of peace and to serve as the backbone of our national defense, if war again comes. This very faith of the public in our present executive is in itself a tower of strength and Congressmen, who are wavering in their decision as to whether or not they will support the subsidy bill, should give very careful thought to this factor.

No Sound Reason Yet Advanced for Opposing Subsidy Bill

If facts instead of misinformation are given to the public, there is little reason to have any apprehension as to how they will expect their Congressman to vote on the pending bill. The opponents of the measure have not as yet brought out a single good reason why the bill should not pass. The minority report contains nothing of real value by means of just criticism. The contentions advanced are captious and have little or no bearing on the great underlying principles involved. For example, several pages of the minority report are devoted to the enormous profits made by certain American steamship lines during and just after the war.

What has that got to do with the question? Anybody could make money during times such as we have passed through. No doubt the proprietors of many peanut stands may have made profits of 600 to 1,000 percent during those inflated days. The only difference is that the Government took away most of the shipowners' profits by means of war and excess profit taxes, whereas the itinerant peanut vendor, and like gentry, placed their ill-gotten gains in the family stocking and probably are now living in comparative luxury in their native countries.

Several tables of comparative wages on American and foreign ships are published for the years 1916, 1917, 1918 and 1919, all of which, like "the flowers that bloom in the Spring, have nothing to do with the case" as it exists today, and will not in the future. There is no question in the minds of men who know, that wages paid to officers and men on American ships are now and always will be higher than those paid for like services on foreign ships. The American farmer and the American mechanic are better paid, and should be, than similar vocations in foreign countries. Is it right or fair to expect that Americans who go to sea in American ships should have their standards of living lowered because of that fact? There is now and always will be a higher cost of ship production in this country as compared to similar activities abroad, for precisely the same reasons that exist for the better paid farmer and mechanics. These

basic facts must not and cannot be lost sight of in the consideration of our merchant marine.

Subsidy Bill Means Economy—Not Extravagance

An attempt is now being made in high congressional sources to place the subsidy bill in the list of great Government extravagances. Nothing could be further from the truth. And it is difficult to understand how anyone with sufficient mentality to be elected to Congress can arrive at such a conclusion, after he has given the subject a fair and impartial diagnosis. No doubt many of these legislators are sincere in their convictions and, if they could stop looking at the matter politically and treat solely from the standpoint of statesmanship, they would change their conclusions. As to direct costs of the subsidy, plain ordinary arithmetic, and not statesmanship, is all that is necessary to convince any fair-minded person that this bill should be classed as Governmental saving, instead of an extravagance. Let any one interested make his own calculations based on the following indisputable facts:

(a) By direct appropriation we are now making up the losses of Government operation of ships, to the tune of $50,000,000 per year.

(b) The average amount which will be expended, if the subsidy bill is passed as written, will not exceed $35,000,000 annually, for the entire period of ten years.

(c) We have today in Government ownership a fleet of vessels costing over $3,000,000,000, which, under existing conditions, can hardly be given away. For each month of delay the deterioration on this fleet is enormous and in addition large sums of actual cash must be expended for caretakers.

(d) Passage of the subsidy bill will enable private owners to buy and operate these ships in competition with foreign ship operators. This fact will enhance the sales value of this fleet not less than $300,000,000, and possibly $500,000,000, all of which will be paid into the United States Treasury during the next ten years.

Now so far as the Treasury is directly concerned, and incidentally the great American taxpayer, if any fair-minded citizen can figure out how this bill will be "another drain on the Treasury," "a reckless waste of Government funds," etc., etc., as has been declared, I would like to be shown. Verily the plain ordinary rules of arithmetic would have to be re-written and the laws of common sense reversed, if any such conclusions can justly and fairly be arrived at.

Indirect Benefits No Less Important

The indirect benefits which the nation will receive in the fostering of our agriculture and commerce, and the sense of security from attacks of enemies in time of war, are so immeasurable as to defy statistical enumeration. There statesmanship and vision must fill in the columns which arithmetical computations will fail properly to show.

If every American citizen would carefully weigh basic facts in this brief campaign of education we are going through, and not listen to the misrepresentations and quacking which are being spread broadcast throughout our land, there need be no fear as to the ultimate results. What splendid opportunities await our representatives in the House and Senate to make known the basic truths underlying this question of a merchant marine! Let them rise above the carping criticisms of the minor details of the measure now before them and enlighten the public as to the fundamentals underlying the possession of an adequate merchant marine. The President of the United States says it is the most important piece of legislation confronting the country today. Who can say to the contrary, and base his statement on the cold logic of facts?

The Traffic Department, United States Shipping Board Emergency Fleet Corporation, has received advices that the Atlantic Intercoastal Conferences, at a meeting held in New York on June 28, decided that as a result of the withdrawal of the American Hawaiian Steamship Company from the conference the remaining members had no alternative but to throw rates in this trade open.

New White Star Liner Pittsburgh, Which Recently Completed Her Maiden Voyage from Liverpool to Boston and Philadelphia

Triple screw passenger and cargo steamer of 16,600 gross tons built and engined by Harland & Wolff, Belfast, Ireland. Length overall, 600 feet; beam, 67 feet 6 inches; molded depth, 45 feet 6 inches; cabin passengers, 600; third class passengers, 1,800. Propulsion is by combination machinery, the wing screws being driven by four-crank, triple expansion reciprocating engines with cylinders 28, 44, 49½ and 49½ inches diameter with a common stroke of 54 inches, and the center screw by a Parsons reaction turbine. Steam is supplied at 215 pounds per square inch working pressure by 6 double ended, oil-fired Scotch boilers arranged for natural draft. Electric generating plant develops over 1,000 horsepower.

Alien Propaganda Against American Ships

Direct or Indirect Efforts to Prevent America from Safeguarding Commerce and Insuring National Defence Are Unfriendly Acts

By Winthrop L. Marvin*

When Senator James E. Watson of Indiana arose in the Senate recently to rebuke the British Ambassador, Sir Auckland Geddes, for speaking too freely to American audiences against President Harding's shipping bill and a protective tariff, Mr. Watson voiced in parliamentary but earnest language a thought that had long been in the minds of many American citizens. A few days thereafter Sir Auckland departed from New York, ostensibly for a vacation in his own tight little isle beyond the herring pond. There may or there may not be any connection between these two episodes, but there can be no mistaking the fact that the American people are sensitive to anything that looks like interference from foreign quarters with the policies bearing upon American business and the American merchant marine.

American shipping men are perfectly well aware that the aspirations of this nation to possess a merchant fleet comparable with that owned and operated by our forebears prior to the Civil War are not exactly regarded with favor in the United Kingdom. Up to a few days ago the British newspapers dealing with maritime and mercantile affairs were singularly incautious in attacking the shipping subsidy bill of our National Administration and were openly hoping and predicting that it would fail. These British editors are apparently oblivious to the fact that some 10,000,000 gross tons of shipping had been built or started in the United States for the primary purpose of saving Great Britain and France and Italy, and incidentally the world, from the onslaughts of the Huns. Most of these ships were built in a hurry, many of them, perhaps, not on the wisest plans. Because of the emergency they could not be called typical products of American shipbuilding. Confessedly they had their faults, and since the armistice these faults have been constantly paraded in the British press in a manner that cannot be said to be consistent with the best ideals of international propriety.

Our Coastwise Policy Criticized

But these things are trivial in comparison with the very frank campaign which the distinguished British Ambassador had plainly been making in the United States, notably in public addresses chosen for deliverance at those great mid-Western maritime centers of Minneapolis and Chicago. At Minneapolis, in a set speech before the Civic and Commerce Association on November 4, 1920, Sir Auckland had dropped an admonition, which he was careful to insist was not at all a threat, that, if the United States government extended its coastwise policy to include the Philippines, there might be some very serious reprisals from Great Britain. Though his language was not at all boisterous, his meaning was clearly evident in what the British diplomatist said. In the course of his address at Minneapolis he spoke at some length on the subject of shipping, saying in particular:

> "Under your laws only American ships may engage in American coastwise traffic. This is a matter for your own decision; we make no comment on your policy. Our present policy is that any ships may engage in British coastwise traffic. I may, however, point out, not in any sense as a threat, however veiled, but as a matter of interest that if a law precisely similar to your coastwise traffic law were adopted by the British Empire, there would be some far-reaching derangements in the business of non-British shipping."

*Vice-president and general manager of the American Steamship Owners' Association, New York.

Language of this kind would never have been uttered by a British Ambassador in hot-tempered, quick-triggered France. Nothing like it as against Teuton aspirations for a merchant marine would ever have been uttered by an envoy of His Britannic Majesty in Germany. Of course it is different in the United States. Our people are historically more tolerant, not to say thick-skinned. And neither Minneapolis nor Chicago can be said to be as profoundly interested in the unfolding of the American merchant flag at sea as Boston or New York or Baltimore or New Orleans. Nevertheless, under the circumstances these words of Sir Auckland Geddes at Minneapolis were words that might better have been left unsaid.

Similar American Interference Hard to Imagine

It is impossible to imagine the American Ambassador at the Court of St. James in a public address at Birmingham or Manchester prior to the writing of the agreement between the British government and the Cunard Line for the enormous subsidy that produced the *Lusitania* and *Mauretania*—it is impossible to imagine the American representative in Great Britain using words similar to those which Sir Auckland Geddes employed to his Middle Western audiences. As a matter of fact, no American Ambassador in Great Britain at that time would have even remotely mentioned the Cunard contract, to say nothing of entering an adroitly veiled protest against its making. When the British Parliament, without a dissenting vote, directed the loaning of about $12,-000,000, at 2¾ percent, to the Cunard Steamship Company for the building of the two greatest and fastest steamships in the world, and at the same time approved an annual subsidy of $1,100,000 for twenty years from which the loan could be repaid, the Parliament was placing an absolute barrier across the path of the development of a great trans-atlantic American steamship service without some equivalent aid from the United States. Yet it did not occur to any American official to interfere with this new and formidable British maritime procedure or to suggest that it was nobody's business, except the business of the British government and people themselves.

They do these things differently in America and in Great Britain. Sir Auckland Geddes saw no reason why he should not follow up his Minneapolis address with other addresses in various parts of the United States. What Senator Watson quoted Sir Auckland as saying in his Chicago speech was something to the effect that the United States, having two-thirds of the gold in the world, might well employ the service of British ships in part payment of debts which Great Britain owed us. Later, I believe that the British Ambassador pleaded that his actual words were misunderstood—that he did not utter exactly this language. But there has been no disclaimer whatsoever of the very much more aggressive and insistent previous statements at Minneapolis.

There has been a great deal of recent talk about alien propaganda against the American merchant marine. There are those persons, American and otherwise, who are given to insisting that there is not and never has been such propaganda in America. Senator Watson manifestly is one of those who are of a different way of thinking—and when he spoke in dignified but emphatic criticism of the activities of Sir Auckland Geddes he also referred to the outspoken

arguments against the American protective law that were being proclaimed by the Italian Ambassador, Signor Ricci. It may or it may not be a mere coincidence that shortly after Ambassador Ricci also departed from the shores of the United States.

Shipping Bill Unpopular in Foreign Countries

Americans who receive copies of the European press can have no doubt whatever in their minds that the American shipping bill is exceedingly unpopular in the commercial ports and the seats of government on the other side of the Atlantic. Every week brings accumulative evidence of this fact when the issues, not of the sensational but of the solid, conservative European journals, are delivered on this side of the Atlantic. If Europe were able to dictate the division on President Harding's shipping bill in the American Congress, that measure would not receive a single vote.

It matters not at all, apparently, that the European nations —Great Britain first of all—long years ago themselves set the example of subsidizing or otherwise assisting their National shipping industries. American statesmen who can see in shipping subventions nothing more than "raids upon the treasury" never used more violent language in denunciation of our shipping plans than the journals of the maritime countries beyond the Western Ocean. They hate the American shipping subsidy bill because they fear it, as more than one of the assailants have had the frankness to declare. Thus *Syren and Shipping,* London, of March 8, 1922, laments that "There is cold comfort for British shipowners in President Harding's message to Congress supporting the proposals of the United States Shipping Board. Whether the desired subsidy will be forthcoming remains to be seen. It has been demanded before and not granted. But the present campaign for State aid is far more potent than its predecessors." Subsequently, on March 22, 1922, this same London journal, having studied the full text of the measure, adds: "An examination of the text of this 'Merchant Marine Bill, 1922' does not lead us to alter our views either as to the earnestness of its sponsors in their efforts to establish an effective mercantile marine, or the seriousness of the competition which would follow the inauguration of such a wide-reaching plan as is suggested."

President's Patience Strained

It is not improbable that President Harding had Sir Auckland Geddes' unwise Minneapolis utterance and the threatenings of the transatlantic press in mind when, in his recent letter to Mr. Mondell, floor leader of the House of Representatives, he said:

> "Let me point out what I believe to be a well-screened source of opposition to an outstanding and confident American course in this matter. No well-developed maritime power of the Old World is craving the development of our shipping. We cannot complain thereat. I confess an admiration for the national spirit which always thinks of the interests of the homeland first. I crave its manifestation here at home in solving this problem. Other nations know the value of sea carrying as an adjunct of trade, and the individual discouragement abroad to our worthy aims—a discouragement often insidiously disseminated here—ought to argue an American interest no longer to be ignored."

Our American President is the soul of patience and good humor. But he felt convinced that it was imperative to speak out when he framed these words—and the significance of them will not be lost upon the country. Those American citizens who read first the anti-shipping arguments of foreign origin and then peruse the arguments of those American statesmen from the inland States who are fighting the shipping bill in Congress cannot but be struck by the close similarity not only of the ideas but of the language of the foreign and domestic outgivings on this subject. Sir Auckland Geddes' protest that Great Britain never bestowed any shipping subsidies is echoed in identical language in the recent minority report from the Committee on the Merchant Marine and Fisheries. Yet all along the Atlantic and the Gulf coasts there are thousands of practical American shipping men who know very well the history of the Cunard Line, of the Royal Mail Steam Packet Company, of the Peninsular & Oriental and of other National steamship services which connect the United Kingdom with the chief ports and markets of the world. These men all know that it is as accurate and just to say that Great Britain never granted steamship subsidies as it would be to declare that the United States never had any system of protective tariffs! A British Ambassador may "get away" in Minneapolis with an assertion that such things as subsidies to ships have never been known in the United Kingdom—but in Boston, or New York, or San Francisco such a remark would merely win for Sir Auckland the reputation of being an unconscious humorist.

Europeans Know Bill Will Help American Shipping

Those editors, shipowners and shipbuilders of Europe who are openly carrying on a propaganda against the American shipping bill have an undoubted right to protest against American shipping legislation—in their own newspapers, their own ports and at a distance. They know as well as do American shipping men that this proposed bill of President Harding is a formidable measure—that it will most certainly result in a substantial increase of the American merchant marine and naval reserve, and that it will operate to promote American commerce and to strengthen American resources for the National defence.

For their own reasons these gentlemen would, of course, prefer to have America continue to be weak upon the seas. But our kin and friends of Europe have no shadow of a right to make any effort to project their propaganda, through their diplomatic representatives or otherwise, to American soil, be it in Minneapolis or Chicago or Washington. In our own country this problem of the American merchant marine is a problem to be settled by the American people and their Senators and Representatives in Congress, without foreign advice and without foreign interference.

Former German Interference Proved

During the years preceding the world war there was a very open and conspicuous propaganda in this country against any effort whatsoever to strengthen American ocean shipbuilding and navigation. The Gallinger shipping bills in particular were violently opposed in the American press throughout the country by statements made directly by the official heads of the great German steamships companies, the North German Lloyd and Hamburg American. Unquestionably these arguments had a certain effect, particularly on the considerable "German vote" in the Middle West and in Congress. The full character and extent of this German propaganda could not at that time be ascertained by those who were interested in the development of the American merchant marine. But when the United States itself entered the world war in 1917, our government seized the head offices of the German steamship magnates in New York, and in these offices confiscated great quantities of correspondence, including, it is understood, letters that had passed between these German magnates and their hired agents and representatives in Washington. These records are now in the possession of the United States Shipping Board or of the Department of Justice.

What was conjectured is now known to be a fact, that the heads of these Teutonic corporations had their men in Washington to report upon all developments calculated to upbuild an American merchant marine, and that instructions were given as to how these efforts could best be defeated—as they were defeated by a very narrow vote, from States where the German element was strongest.

British Interests Warned

All this is history now—it is of the past. But I would venture to suggest to perhaps overzealous representatives and

agents of British steamship interests and their "listening stations" in this country, that it would not be exactly a comfortable thing, if it developed that there were a widespread British propaganda here against President Harding's present effort to upbuild American shipping. The American people, because of events preceding and during the world war, have learned to be exceedingly resentful of alien propaganda of any kind. They frankly did not like the recent utterances of Sir Auckland Geddes, as Senator Watson's effective protest has shown. It would be most unfortunate for the continuance of good feeling between the American and the British peoples, if there were any further developments along this line. For it is just as unwise and just as grave an impropriety for British interests of any kind to meddle with the course of American legislation, especially pertaining to the merchant marine, as it would be for American interests of any kind to seek to interfere with the efforts that are constantly and properly being made in the British Parliament and by the British Board of Trade to strengthen further the already formidable power of British shipping.

One point in particular our British kinsmen, if they are real friends of ours, will carefully bear in mind—and that is that the recent Washington conference on the limitation of armaments solemnly agreed that the battleship fleets of the United States and of Great Britain should hereafter be equal, and that the battleship fleet of Japan should bear to them both a relation as of three to five. That agreement is being faithfully carried out, so far as the actual fighting units are concerned, by the three nations most vitally interested. But there should be no need of reminding the British government and people, of all governments and peoples, that effective naval strength is not a mere matter of battle line alone—that there must also be an adequate, effective merchant reserve behind it. As Admiral William S. Sims has lately and wisely said, "The navy of the United States would be of very little value as a defence of the United States and our possessions, if it were not for the merchant marine."

The American aspiration for the possession through National aid of an adequate merchant marine and naval reserve is an instinctive sequel of the Washington conference, without which a great purpose of that conference will be nullified so far as concerns America herself. Our nation requires a proper merchant fleet for the safeguarding of our commerce and also as a vital resource of the National defence—and any effort, direct or indirect, on the part of a foreign government and people to thwart America's aspiration along this line ought to be understood on both sides of the Atlantic to be an effort so unfriendly that it should be inconceivable.

Further Attempts to Delay the Ship Subsidy Bill

Responsibility Rests with Congress—President's Attitude Unchanged —Sentiment in Middle West Favoring Ship Subsidy Grows Stronger

By Harold F. Lane

Washington, D. C.

OPPOSITION among Republican members of the Senate to the efforts of the President toward prompt and favorable action on the ship subsidy bill has made its appearance since consideration of the bill in the House was postponed in order to enable the House to take an adjournment to August 15. A recent canvass of the Republican senators, although the exact results were not announced, is said to have developed the fact that there is a strong sentiment against bringing the measure up this summer, and at a recent meeting of leaders of the Senate at the home of Senator Lodge of Massachusetts, steps toward side-tracking the bill were discussed. Among those present, agreement was reached in favor of postponing the bill until after election and while the President was away at the time it is understood that the results have since been reported to the President by Senator Lodge.

President Harding has been so busy of late in his endeavors to deal with the coal and railroad strikes that he has been unable to give very close attention to the prospects of the shipping bill but undoubtedly he is being subjected to considerable pressure to alter his determination to call an extra session of Congress, if the bill is not acted on at this session. There is also the strong probability that the disposal of the tariff and other pending legislation will be allowed to consume so much time that only a short period would in any event be left available for a special session before the new session begins in December. The President has let it be clearly understood, however, that responsibility for the delays rests squarely upon the heads of Congress.

Attitude of the Middle West

The legislative situation in the Senate is advanced as the principal reason for postponing the subject but it is also obvious that senators from the middle west are still somewhat sceptical as to the popularity of the bill and are therefore afraid of it before election, especially since it has been complicated by the controversy regarding liquor selling on board American ships. The weekly bulletin of the National Merchant Marine Association points out, however, that "The argument is still advanced by the advocates of delay that the interior is opposed to aid to the merchant marine, but nothing tangible is produced to back up the claim. It is still true that not one commercial organization in the United States has gone on record as against the shipping bill while hundreds have come out in advocacy of it. The sentiment of the press is growing stronger, a number of papers that have not hitherto taken a stand either way have declared editorially for the proposed legislation, and some that have been against the measure are now for it. In the farm press is found the bulk of the opposition but in most every instance the character of the comment on the situation shows that hostility to the bill is based on a misunderstanding of its purposes and effects."

Many representatives of the agricultural interests that have been inclined to oppose the bill are said to have received "a new slant" on it as a result of a meeting at the White House on June 28 at which President Harding explained to a number of representative farm leaders the reasons why he thought the farmer should support the proposed legislation. For two hours the President answered the questions of his guests and he was assured that every effort would be made to make clear the principles of the bill to the farming population.

While all of those present were not willing to admit that they were convinced it was learned that many misunderstandings were cleared up that had previously been the cause of much of the opposition.

A special committee of the National Industrial Traffic

League, which is regarded as the most representative organization of shippers in their relations with railroads and transportation generally, has made a study of proposed changes in the maritime laws and has recommended to the executive committee of the league that the organization favor the passage of the ship subsidy bill and the repeal of Section 28 of the Jones law.

The fact that the Democrats are not prepared to make a party stand against the bill was indicated when the minority report of the House committee on merchant marine and fisheries on the revised bill was filed on June 27. Of the seven Democrats on the committee, only three endorsed the report in full, Representatives Davis of Tennessee, Hardy of Texas and Bankhead of Alabama. Representatives Bland of Virginia and Briggs of Texas signed a postscript to the report stating that they were "substantially in accord with it and opposed to the bill," while Representative Lazaro of Louisiana and Cullen of New York failed to sign the minority report.

Hearing on Liquor Sales

The vexed question as to the legality of sales of liquor on American vessels outside the three-mile limit was given an exhaustive public hearing before Attorney General Daugherty and officials of the Department of Justice on July 13 as the result of a request from the Secretary of the Treasury for an opinion on the subject. Chairman Lasker, not wishing to agitate the subject, had not previously asked for an opinion from the Attorney General but had acted on the advice of his own counsel in the matter. The hearing was on two points, as to whether the eighteenth amendment and the national prohibition act prohibit possession, sale and transportation of intoxicating liquors on American ships on the high seas, and as to whether foreign vessels may bring liquors as ship stores within the three-mile limit. The Shipping Board was not represented at the hearing, although a copy of the opinion of General Counsel Schlesinger was filed. Arguments were made on behalf of the American Ship Owners' Association, the Anti-Saloon League, the Prohibition Bureau and various other organizations.

Bill to Reduce Shipping Board

Senator Borah of Idaho has introduced a bill in the Senate to reduce the number of commissioners of the Shipping Board from seven to three, for the purpose, he explained, of saving four $12,000 a year salaries. One of the effects of the bill would be to break up the present system whereby representation on the board is assured to all sections of the country, the appointments being on a geographical basis. The Borah bill provides that the President should not name more than one commissioner from any state nor more than two from the same political party.

Launching a Fighting Seaplane from the U. S. S. Maryland by Means of a Newly Developed Catapult

So successful have the tests demonstrated the launching of a plane from a battleship by a catapult, that each of Uncle Sam's battleships will be provided with fighting planes and a catapult to launch them from her deck. The United States is the sole possessor of this practical plane catapult.

Recent Developments in Marine Insurance

Barge Canal Pool—Hull Conditions Bad—Suez Canal Recognizes Our Classification—Radio Guides Ships—Oil Burning Recommendations — New English Average Rules — Cuban Conditions

By "Bordereaux"

IN harmony with the popular agitation for a more extensive use of the New York State Barge Canal marine underwriters are co-operating in a movement in conjunction with State officials that should result in attracting traffic through a substantial reduction in insurance rates on hulls and cargoes routed via the canal. The proposition is to form a syndicate of underwriters who will cover on the canal provided the State authorities inaugurate certain improvements and safeguards that should increase efficiency and transform the customary underwriting loss into a perceptible margin of profit. The insurance companies have been regularly losing money on their writings on the barge canal, chiefly because of the large number of strandings in the narrower parts. State Superintendent of Public Works Cadle has been conferring with the underwriters and has expressed a willingness to meet them half way in the improvements suggested by them. These improvements take the form of additional safeguards to navigation; such as buoys, efficient lock approaches and the expansion of wrecking, dry-docking and repair facilities. Substantial rate reductions will be granted by the underwriters when these improvements have been made. It is only fair to the insurance men to state that they are as anxious as any other class of New Yorkers to attract shipping to the canal through the practical medium of lower costs.

In this connection it might be added that the underwriters are taking a cordial interest in the plans now being perfected for a line of seventeen motor barges for use in the canal and Great Lakes, by which it is planned to make possible extensive shipping operations between New York and Duluth without breaking bulk. A company is being organized to produce and operate the fleet as soon as additional capital has been subscribed. Theodore D. Wells, a prominent naval architect, is the designer. The American Bureau of Shipping has been asked to class them when completed. Each barge is to have a cargo capacity of one thousand tons, will be of steel, 220 feet in length and with a Diesel electric drive. Seaworthiness is to be the special consideration, for it is proposed not only to use these barges on the Great Lakes during the navigation season but to employ them in the coastwise trade for the remaining four months of the year.

Hull Conditions Bad

ONE of the safest marine insurance authorities of England is Sir Edward Mountain, chairman of the Eagle, Star & British Dominions. In an address to the stockholders of that company he recently declared that hull conditions in general continue to be extremely unsatisfactory and that claims for repairs, directly or indirectly, absorb the majority of the premiums. Under the old Hull Agreement the companies had enjoyed a reasonable average profit, but when that went to pieces last year disaster set in. Increasing competition and the reduction in values induced certain underwriters to withdraw at that time and the combination could not be longer maintained. After a year of wide open competition the full extent of their folly may now be measured. Premium receipts have gone off from forty to fifty percent, taking into consideration the reduced values on which the steamers were placed.

"In my opinion," said Sir Edward, "such a reduction was absolutely unwarrantable and could hold no prospect whatever of profit, but only a certain loss; in consequence of which, much to our regret, we refused to renew the bulk of this business, even although by so doing we gave up connections we had had for a great number of years."

Suez Recognizes Our Classification

IT has been a great satisfaction to American underwriters, as doubtless to all others of their countrymen, to have the authority of the American Bureau of Shipping accepted by the Suez Canal Company. Not but that it ought to be recognized as well there as elsewhere, but because considerable serious trouble has been obviated by the Suez authorities granting a belated inclusion of our national classification society among those of other countries. It will be remembered that the Merchant Marine Act of 1920 made the Bureau the official classification society of the United States. What, then, was the amazement of our underwriters and shipping interests to learn that the recently promulgated order of the Suez Canal Company ignored the Bureau altogether in its designation of classifications under which tank steamers carrying bulk oil and gasoline would be allowed to make use of that important waterway. That order included only Lloyds, the Bureau Veritas, German Lloyds and the British Corporation of Glasgow, as classification societies under which that type of vessels passing through the canal could be certified. It is estimated that, had this order stood, it would have denied the canal to more than 900,000 tons of American vessels, including those of the United States Navy. As good luck would have it, Stevenson Taylor, president of the American Bureau of Shipping, was at the time in Europe on a visit of inspection of the society's Continental agencies and he was promptly cabled the news and at once got in touch with the Suez authorities and had the assurance given him that the order would be instantly corrected to include the Bureau. It was declared to have been an oversight. Classification is required of tank ships in order to make sure that certain technical details of construction have been complied with so that accidents may not happen that would possibly block the waterway.

Radio to Guide Ships

MARINE underwriters are taking the liveliest interest in the announcement of Signor Marconi that radio can be utilized to guide vessels in fog and storms. The great inventor made such conclusive demonstrations of the possibilities of the short wave, in his recent address before the American Institute of Radio Engineers, that insurance men are confident that it is only a question of a few more developments before this great agency of protection will become commercially available. The time has passed when anyone questions the conclusions of the inventor of wireless. Signor Marconi illustrated his points by the use of a toy apparatus that sent across a space of twenty feet. He said that the possibilities of the short wave have been universally neglected but that they are capable of as high a development as the long distance waves of

hundreds and thousands of meters in length. He demonstrated that a shaft of radio waves might be reflected in any desired direction, as light from a mirror, and that in this manner a lighthouse could guide a ship through a dangerous channel in fogs and storms. With waves of three and a half meters he has reflected radio signals six miles and waves of fifteen meters have been reflected for ninety-nine miles.

New English Average Rules

AT the recent annual meeting of the English Association of Average Adjusters a new rule of practice was adopted with respect to the contributory liability in general average of ships' stores, bunker coal or fuel. It is as follows:

That underwriters insuring ships' stores, bunker coal or fuel, destroyed or used as part of a general average operation, shall be only liable for those articles as a direct claim on the policy when they formed part of the property at risk at the time of the peril giving rise to the General Average Act.

Adoption was also accorded the following probationary rule:

That in practice, for the purpose of ascertaining the liability of underwriters for contribution to general average and salvage, deduction shall be made from the insured value of all losses and charges which constitute a deduction from the contributing value and for which the insurer is liable.

Oil Burning Recommendations

ONE of the important points recommended in the report of the Marine Fire Hazards Committee, recently adopted by the National Fire Prevention Association, has to do with oil burning equipment on vessels. It reads as follows:

It is strongly recommended that systems whereby oil is pumped from the tanks to the burners be used; but in cases where a pumping system is deemed impracticable and the use of gravity feed is desired, special permission shall be granted installation and detailed plans submitted and approved.

Pumps shall be in duplicate, of an approved design, well secured against leaks under a test pressure 50 percent in excess of the designed pressure of the system carried.

Whether pumps are located inside or outside of the fireroom, gear shall be installed for operation from deck of stop valves on each tank and throttle valves on both service and booster pumps. This provision does not apply to fuel pumps on motor vessels.

On steam vessels burning oil of a flash point lower than 150 degrees F., closed cup, the pumps handling such oil shall be located in a compartment separated from the rest of the machinery space by gas-tight bulkheads and accessible therefrom only by a gas-tight door.

The piping and spindles of fireroom controls shall be made gas-tight where they pass through the pump room bulkheads.

This pump room shall be provided with induced ventilation always sufficient to reduce the pressure therein slightly below that in the compartment from which entry is made.

Cuban Conditions

ALTHOUGH port conditions at Havana are greatly improved and shipments are now passing through the Custom House and being removed by consignees within five days after the arrival of vessels, there still remain many sensational evidences of the astonishing congestion that prevailed there a year ago and these continue to disturb economic conditions. Forty-nine warehouses contain more or less of them and this merchandise appears to be without owners and will eventually be sold at auction by the Cuban authorities for the payment of fees and other charges that have accumulated upon them. It is being asked, "What is to become of these goods before the Cuban Government disposes of them and what is to be the position of the marine underwriters in the controversy?"

Albert R. Lee, E. A. Palmer and Mr. Amberg, counsel, of the admiralty firm of Harrington, Bigham & Englar, compose the group that is negotiating in Cuba on behalf of the underwriters. They have found a very complete pilfering of cases of merchandise of every description. Worthless rubbish of a weight rudely approximating the former heft of the goods filled the cases and sometimes there was nothing at all in them. It is not believed that the responsibility for these losses will fall upon the underwriters but rather upon either the shippers or the consignees, as the facts shall develop upon legal inquiry. It appears that many stevedores and dock workmen whose wages came to them at uncertain intervals tided their financial necessities over by helping themselves to such merchandise as appealed to their fancy. In one instance a shipper called in an authority to advise him as to his position. He had shipped forty-three cases of goods to Cuba a year ago and only recently took steps to re-ship the merchandise back to the United States. He found forty-one of his cases absolutely empty and the other two partially pilfered.

One of the chief sources of loss to Americans has been the notoriously inefficient packing they employed. Such inherent defects were found to obtain much more frequently with American shipments than with those that had come from Europe.

English Insurance Conditions

ADVICES from the United Kingdom and the first-hand observations made there by recently returned visitors from the United States all tend to show the same slackness of the marine insurance market that has given so many of our own underwriters anxious hours these many months past. The underwriting room at Lloyds is said to be only sparsely populated nowadays and many of the leading company officials find little occasion to run up to town. Next to nothing is being written and what is placed is at rates absurdly low. It has been discovered that the brokers, both in the British Isles and in America, have been decidedly more alert than the underwriters and have secured acceptances at rates much lower than conditions justified. Only now the insurers are awaking to the situation and are beginning to demand something more equitable in rates. The tendency from now on is said to be decidedly in the direction of better quotations. It is also of interest to learn that the British underwriters have been realizing a nice profit upon their American business. Hull rates have been so low, and the valuations so enormously reduced, that many of the more astute underwriters are declining to accept further business at prevailing figures and prefer to let business go, even though it has been on their books for years, rather than face a certain loss with no possible hope of profit. Raiding of rival office accounts continues there, as here, to be the leading summer pastime. Now and again a prominent company is found announcing that it has decided to abandon direct writing altogether for the time being. Certainly, few men in marine insurance today have ever known the market to be so slack or so replete with discouraging conditions.

Would Insure a Ship's Life

CERTAINLY the Germans are nothing, if not ingenious. A group of savants of that country is engaged upon a scheme for the application of life insurance principles to such inanimate objects as ships and houses, and several companies have been formed at Berlin and Hamburg for the effecting of this class of protection.

Simplification—Has It a Place in Shipbuilding?

By N. C. Wiley

The urgency of the need for reducing American shipbuilding costs needs no elaboration and the following is a suggestion of the possibilities of a new and untried step in this direction.

STANDARDIZATION is a term which, when applied to shipbuilding, has entirely different meanings for different persons and therefore the term as used in this article must be defined. Standardization, as used herein, means the development, by a shipbuilder or by the industry as a whole, of a standard line of fittings or ship parts. It is far from the writer's intention to urge standard design of ships and yet this is the construction frequently given the term. As yet standardization, although practiced to a greater or less extent in all shipyards, has not been unified by either builders or owners. No successful or thorough attempt at such standardization has been made by any large group or organization.

Simplification is a development of standardization by elimination which can best be defined by examples. If a line of cleats is designed in ten sizes for one type, six sizes of a second type and three sizes of a third, and these cleats do away with the necessity of further cleat design whenever a new ship is built, standardization has been attained. Now, if the first type can be reduced to five sizes, the second to three, the third eliminated and still all necessary requirements met, we have simplification.

> *"We have probably the highest ingenuity and efficiency in the operation of our individual industries of any nation. Yet our industrial machine is far from perfect. The waste of unemployment during depression; from speculation and overproduction in booms; from labor turnover; from labor conflicts; from failure of transportation, fuel and power supplies; from excessive seasonal operation; from lack of standardization; from loss in our processes and materials—all combine to represent a huge deduction from the goods and services that we might all enjoy, if we could do a better job of it.*
>
> *"One hundred percent is never possible in the material world, but the primary duty of organized society is to enlarge the lives and increase the standards of living of all the people, not of any special class whatever. The opportunity for advance in living standards lies more surely in the steady elimination of these wastes than in great inventions."*
> —Herbert Hoover.

If patterns are made for valves in cast iron, cast steel and composition for high, medium and low pressures in angle, globe and cross types in sizes at every half inch from ½ inch to 6 inches, then at every inch to 12 inches, there would be 286 valves and standardization would be nearly attained. If by combination, elimination, compromise and agreement this line can be reduced to sixty varieties, that is simplification. If the same yoke is used for a certain six of the valves instead of two yokes for the six, that is further simplification.

Simplification is the final step in standardization and it is that step in which lies the most economy. It is only simplified standardization that will effect a material reduction in costs. Yet it is this final step that is the hardest to take, requiring the most co-operation, thought, patience and foresight.

Satisfactory Solution Possible

Everyone who has to do with ship fittings tries to standardize and to simplify but meets with so many difficulties that the result is far short of perfection and by individual effort no satisfactory and abiding solution is possible. This situation is not caused by any lack of skill or interest on the part of shipbuilders' technical staffs. To establish a complete standardized line of both hull and engine fittings would take time and concentration on the part of experienced men, but there would be nothing impossible about it. The failure has been due to the fact that operators, marine superintendents, port engineers and inspectors have not adopted the same standards and refuse to recognize the builders. This refusal may be justified, as it is obviously possible that so-called standards may be poorly designed and not of a quality to give satisfaction. At times, however, it seems a mere matter of upholding a difference of opinion or of improperly written specifications.

The difficulty was aggravated by the boom of two years ago, but has always existed. The necessity of a solution is more acute in the reaction of today than ever before in the checkered history of the American merchant marine. For operators to maintain a technical staff large enough to criticize and check the plans of every detail of construction and to incorporate in the specifications a detailed description of all systems and individual fittings is at present often considered necessary. This is a burden to the owner in office overhead, in expense passed on to the owner by the builder, in delayed completion, disputes and in diversion of the staff from a more important duty—inspection of workmanship. The expense and folly of submitting detail plans for approval are not fully realized by the average operator. He is a business man with no time to verify the assurance given him that a satisfactory ship can not be obtained in any other manner.

Typical Examples

Before the war, a company building two ships specified and insisted on having rigging screws several sizes larger than the builder had hitherto used on the given sizes of rope. Furthermore, the rope was iron and of less strength than steel rope of the same size. Comparisons with manufacturers' quoted strengths, builders' and navy standards, classification requirements, mathematical analysis, all were of no avail; the representative's experience taught him that the specified sizes were necessary. If this were so, ships are in service with rigging screws which are too small.

Ships for two owners were being built from the same plans. The naval architect for the smaller fleet must have the male and female sockets on his goosenecks and gooseneck bolts reversed from the builders' patterns and the other owner's standard practice. Only recently, and on a rush job, specifications for a flanged copper pipe steam heating system were issued for alterations to one of a large class of ships now fitted with steel pipe and screwed fittings. Neither flanges, tees, laterals nor valves for this purpose were obtainable, with the result that steam heating was the point about which contract delivery was made to hinge. The point here is not so much the relative merits of steel and copper as that a system should be asked on a rush job which was so unusual that neither manufacturers nor a large shipbuilder were in a position to supply the fittings. If such a revolutionary change is desirable, should it not be first the subject of general discussion and mutual agreement?

Only in June a plant which had tried for a month to obtain a 4½-inch high pressure cast steel cross valve had to make one because of the existence of 4½-inch lines in a ship being reconditioned.

The above are just samples taken from the inexhaustible list of cases where simplification has been prevented. It is largely due to the lack of a universally recognized and agreed upon standard of size and type. It has seemed in the past to those actively engaged in the design and ordering of ship fittings that there was no way out of this dilemma. Happily, this is no longer the case. The way out lies in following a path already being blazed by many other industries, many of which are on the verge of a period of prosperity, while shipping is not.

Department of Commerce Interested

The shipping industry, in common with others, can now obtain the assistance of a new government agency as an aid in their solution—an agency started and actively supported by Mr. Herbert C. Hoover. The Bureau of Simplification of the Department of Commerce is referred to. The activities of this organization are increasing in their scope daily and are best described in the words* of Mr. W. A. Durgin, the director:

"The first step is to arrange for securing statistics, or other data, which shall show present conditions and indicate the line for action. For the machinery interests, the representative trade associations would appoint a small contact committee to get in touch with Secretary Hoover and the Division of Simplified Practice. After a conference at Washington, this committee would proceed to survey the machinery field for the Department of Commerce getting figures showing varieties manufactured and the importance of the several items during the last few years. The committee would summarize these data in a report covering present conditions, and would then forward the summary to the Division of Simplified Practice. With this report before it, the division would prepare a tentative list of representatives to the general conference—the personnel of the list being submitted to all trade associations interested and to the United States Chamber of Commerce, the American Engineering Standards Committee and other bodies, to insure that every factor in the field was given proper voice. All the representatives included in the final amplified list would then be invited to a conference in Washington and this conference would proceed to work out such recommendations for simplification as the general discussion should develop. The conference would further decide how frequently similar conferences for revision of the recommendations should be called; and each representative would engage to obtain the approval of his association, firm or other parent body, to the recommendations as finally adopted. Finally, the Division of Simplified Practice, for the Government, would give national standing and publicity to the action of the conference by issuing the recommendation as one of its official series. This series will be numbered in sequence and will be known as 'Simplified Practice Recommendations of the Department of Commerce.' As a part of its service the division will obtain a formal letter of acceptance of the recommendation from each of the bodies represented at the conference and, when necessary, from the individual members of those associations most interested. At regular intervals statistics from all manufacturers and distributors as to the percentage of business done in the simplified sizes will be requested and the division will accumulate data on necessary revision, calling the conferences for such revision at the times originally set by the industry."

It is surprising, that, in spite of the lessons taught by the lack of this very program in 1917 and 1918 and notwithstanding Mr. Hoover's well known interest in the American merchant marine as a necessary component of our foreign and domestic commerce, no shipping interest has as yet approached the Bureau of Simplification. In June the writer was assured that he was the first person to bring the subject to their attention. He was only a few minutes ahead of the beehive manufacturers and they were prepared to call a conference at once.

However, without either owners or builders taking any initiative, future ships are sure to undergo a great deal of simplification, although not enough. It is impossible to have conferences on simplification among the trade and manufacturers' associations of almost every conceivable material and article entering into the equipment and outfit of a ship and not have the effect apparent. Consider the following partial list of industries which have entered this campaign, some of them making their first move in May of this year, others being well advanced:

Asbestos products	Hardware
Automotive equipment	Instruments, electrical
Boilers, steam	Linoleum
Boxes and barrels	Cotton duck
Cordage and twines	Machine tools
Fabricated structural steel	Paint
Gas engines (inc. marine)	Plumbing
Refrigerating machinery	

By the time this article is published many other lines upon which shipbuilding is dependent will be reducing dimensional and color variation in their product.

What advantages will accrue alike to owners and shipbuilders? Some of them would seem to be:

1. Reduced cost of new and repair work due to savings in:
   (a) Design of details
   (b) Patterns, jigs, etc.
   (c) Unusable surplus material
   (d) Economy through quantity production
   (e) Idle equipment
   (f) Discontent among yard and office workers
   (g) Storeroom expense
   (h) Delays
   (j) Accounting
   (k) Estimating
   (l) Purchasing expense
   (m) Administrative expense.

The above are in addition to the savings made in the price, delivery and handling of purchased parts already undergoing simplification as previously noted.

2. Greater speed in both new and repair work.
3. More accurate and dependable workmanship and design.
4. Less expense to owners on account of technical staff having—
   (a) Simpler specifications
   (b) Less checking of detail plans
   (c) Less correspondence
   (d) Less overhead
5. Increased effectiveness and decreased cost of inspection.
6. Decreased expense in and increased possibilities of adapting purchased or leased ships to new operators' requirements.

There is no time like the present for the numerous organizations of owners, operators, builders and designers to let Mr. Hoover know that they are as alive to the opportunity now open to American industry as are other and allied trades. Once started, no harm and much good will result and lasting benefits accrue to all participants. It is as practical a form of subsidy as any that has been suggested!

*From *The American Machinist,* May 11, 1922.

S. S. Princess Louise on Trial

Canadian Pacific Coastwise Steamer Princess Louise

Luxuriously Equipped Passenger Ship for Coastwise Service of Canadian Pacific Railway Built and Engined by Canadian Shipbuilder

By R. Allan, B. Sc.,* and A. F. Menzies, M. I. N. A.†

THE recent addition of the palatial steamer *Princess Louise* to the coastwise fleet of the Canadian Pacific Railway Company draws attention to a very significant epoch in the history of Canadian shipbuilding. Previous to the war, no Canadian shipyard could have competed with any hope of success against the old-established yards of Great Britain; but the war upset all standards of economic values, raising the cost of shipbuilding in the old country to heights hitherto undreamed of. Hence when it was announced about eighteen months ago that the Wallace Shipbuilding and Dry Dock Company, Ltd., of North Vancouver, B. C., had booked the contract for this noteworthy vessel, it was obvious that the Canadian bid was strictly in accordance with prices received from the Clyde and Tyne.

In view of the fact that previous outstanding vessels of the Canadian-Pacific coastwise fleet had been built by such well known shipbuilders in Great Britain as the Fairfield Shipbuilding and Engineering Company, Ltd., Govan, Glasgow; Swan, Hunter and Wigham Richardson, Ltd., Newcastle-on-Tyne, and Bow, McLachlan and Company, Ltd., Paisley, Scotland, it was not surprising that skeptics marveled at the audacity of the owners in placing this contract with a relatively small shipyard. In Mr. Wallace, however, who is the active head of the Wallace Shipbuilding and Dry Dock Company, Ltd., Canada possesses a shipbuilder of the type of the Dennys, of the Lairds and other historic names of British shipbuilding. For nearly thirty years Mr. Wallace has been building ships in Vancouver, including fishing boats, fine stern wheelers for the lakes, tugs, ferries and more recently freight steamers such as the 8,350-ton *Canadian Highlander* and *Canadian Skirmisher*. Moreover, the workmen at the Wallace shipyard are in nearly every case trained shipbuilders, mainly products of the Clyde, Belfast and the Tyne. The results accomplished by such an organization can be seen in the successful completion of the vessel itself, which in beauty of design, luxury of equipment, decorative effect and all around excellence competent critics consider superior to anything in the fleet.

Main Particulars of the Vessel

The principal dimensions of the *Princess Louise*, which has been built under British Corporation rules to their highest class for sea-going vessels, are as follows:

Length overall	330 feet 0 inches
Length between perpendiculars	317 feet 0 inches
Beam, molded	48 feet 0 inches
Depth, molded	27 feet 6 inches
Draft forward	15 feet 0 inches
Draft aft	17 feet 0 inches
Mean draft	16 feet 0 inches

In the design of the vessel and its accommodations primary consideration was given to the Alaska run, but what are known as the triangular and local runs, viz., Victoria, Seattle and Vancouver, and Victoria-Vancouver, had also to be considered, more especially as regards fineness of form, necessitating a very fine block coefficient to maintain with economy the speed of the triangle run, viz., 16½ knots.

Nothing that pertains to the comfort and pleasure of the passengers usually provided on ocean liners has been omitted. Indeed the vessel, with her smoking rooms, dining saloons, observation room, library, suites de luxe, etc., can best be described as an ocean liner in miniature.

Owing to her fineness the vessel will carry only about 700 tons of cargo but her main deck forward has been provided with very large cargo ports, capable of allowing a large limousine to embark without having to take off the top hamper. Altogether this deck can hold about forty cars.

To facilitate the handling of freight, a freight elevator has also been installed forward on this deck. Aft on the orlop deck a cold storage compartment of about one carload capacity has also been provided, in addition to the usual cold chambers for the ship's provisions.

A very complete installation of cargo handling gear has

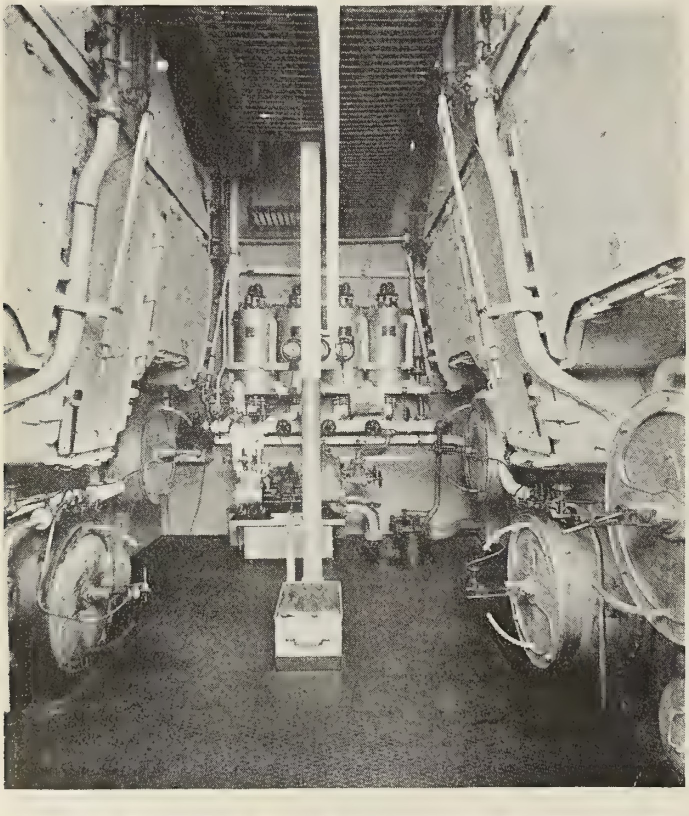
been fitted. There are four 5-ton booms, and one capable of handling 15 tons on the forward mast. The forward hatch is trunked between the promenade and awning decks, and has been so arranged that on the triangular or local run it can be used as a baggage room, the floor being arranged to hinge upwards.

The winches are of the vertical oscillating type, two winches being arranged so that they are handled by one man.

The vessel has very complete mooring arrangements consisting of two warping capstans and one windlass and is provided with wireless telegraphy.



Stokehold, Looking to Port, Showing Oil Fuel Arrangements

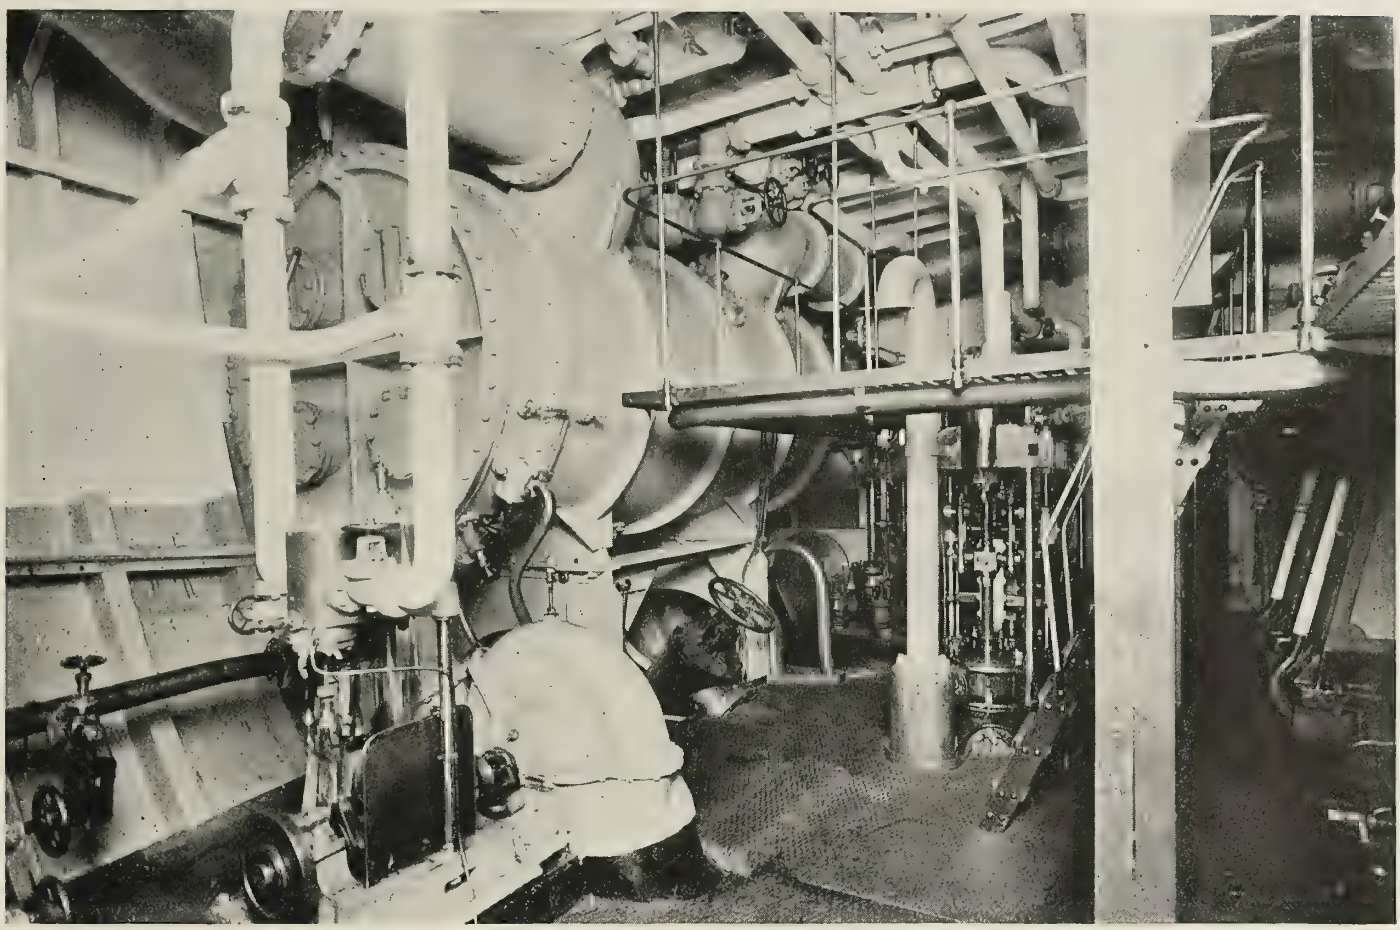
General Arrangement

As shown by the deck plans, there are three decks for first-class passengers and two combined freight and passenger decks. The boat deck contains twenty-nine two-berth cabins, two suites de luxe with separate toilets and combined bathroom. On this deck are also situated the library, with a staircase to the observation room below, the officers' cabins and wireless house. The captain's cabin is a particularly spacious and well-furnished room with a bay window. The library is very handsomely framed in Honduras mahogany with large plate glass windows commanding views ahead and on either side. It contains two very tastefully designed bookcases, with leaded glass panels, embodying Canadian dogwood as a floral motive. The floor is covered with a beautiful pile carpet and very comfortable cane chairs complete the furnishings of what is sure to become the most popular room on the vessel.

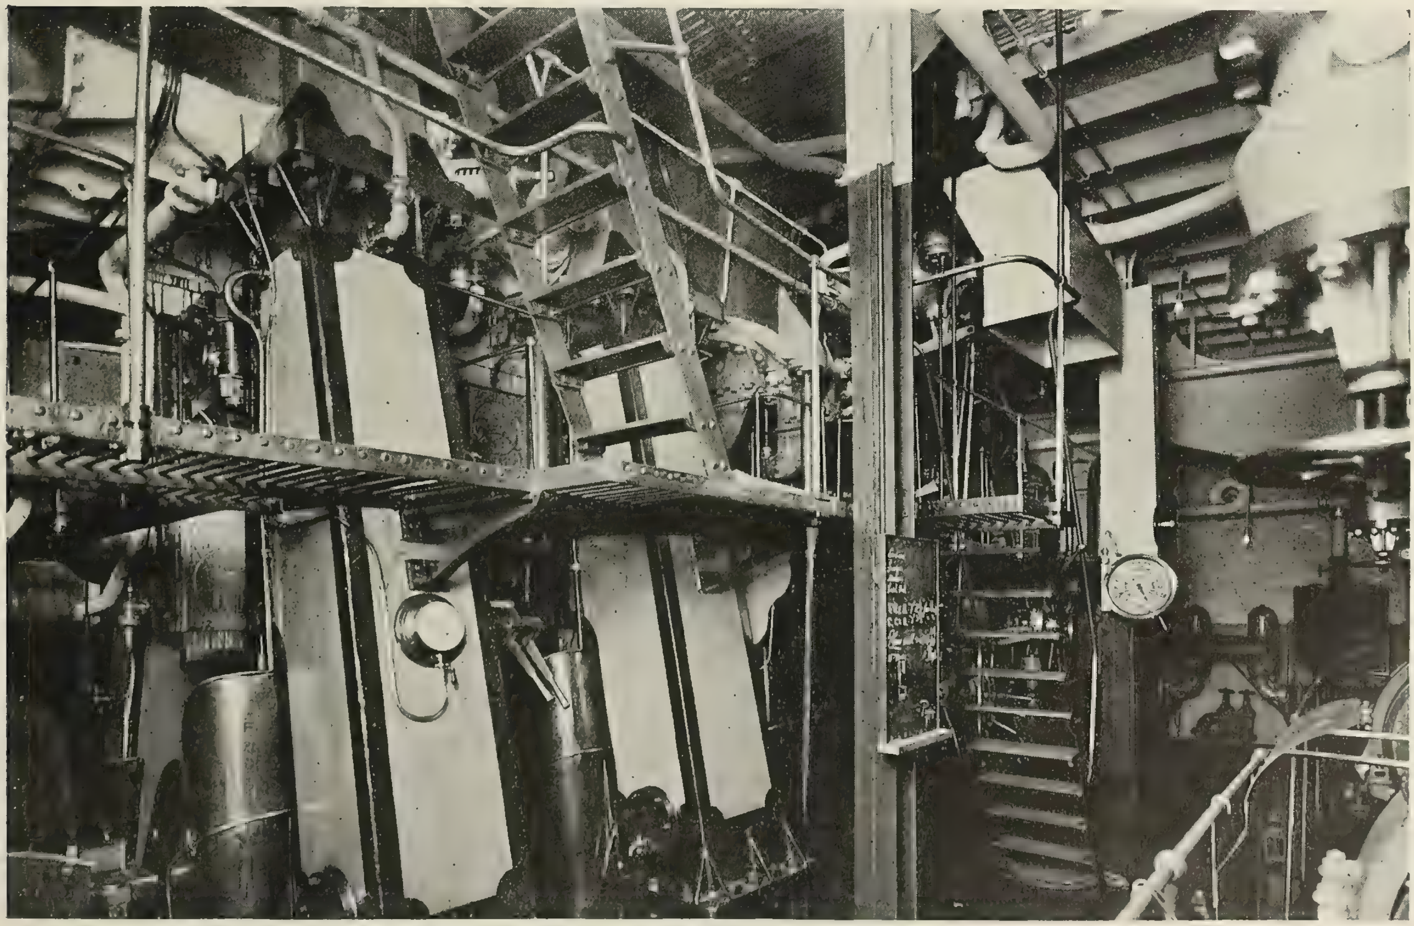
Each deck has been provided with its own public lavatories and bath rooms for men and women.

The promenade deck, with its spacious forward end and wide promenade spaces at the sides, contains forty-two two-berth cabins. On this deck are situated the first class smoking room and observation room. The latter, commanding views ahead and on either bow, is framed in Honduras mahogany. The framing in way of the alcove at the after end is relieved with buttoned mirrors. The pipe trunk in the center of the room also contains a buttoned mirror. The upper portions of the swing doors are of bevelled glass, protected with a brass grill. The floor is carpeted and in front of the cane chairs are upholstered footstools.

The smoking room, at the after end of the vessel, is an exceedingly handsome room, framed in black walnut, with large plate glass windows and a barrel roof overhead with a central light framed in leaded glass, embodying the dog-



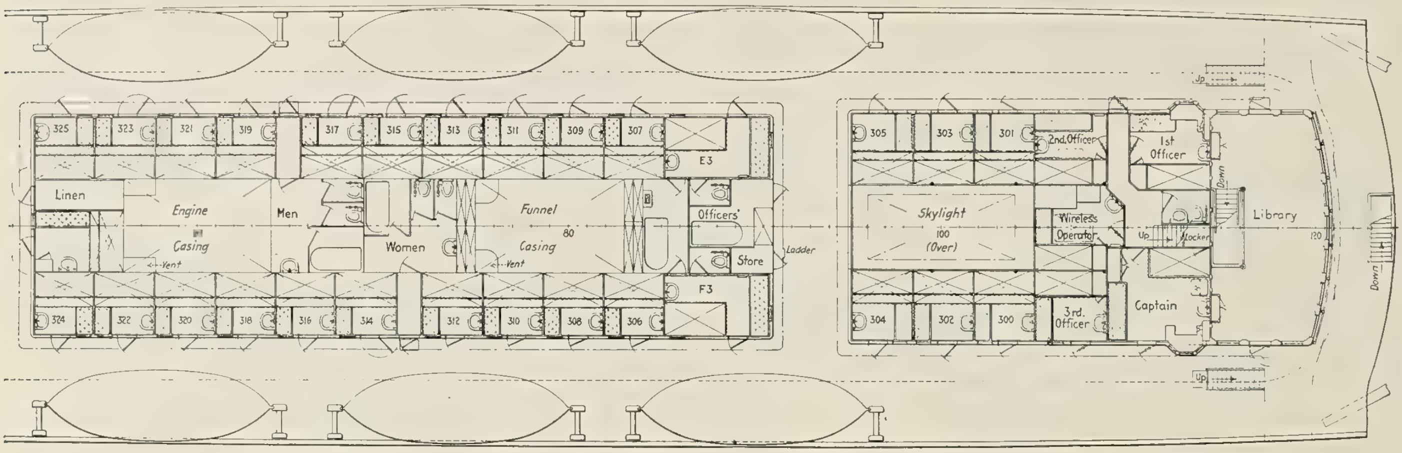
Engine Room, Port Side, Showing Condenser and Auxiliaries



Engine Room of Princess Louise, Starboard Side, Looking Forward

wood as a floral motive. The after and forward ends of this roof also have leaded lights, having as their decorative scheme a representation of the "Siwash Rock" and the "Lions," two well-known local scenic features. The floor is covered with linotile, as are also all passageways on this deck. The forward well is beautifully framed with a white enamel finish. The skylight above has a representation of panels on their upper portions. Leading from the main entrance forward are the barber's shop and baggage room. The waiters and executive officers are berthed forward of the main entrance on this deck.

Aft of the main entrance is the social hall, containing the purser's office and main staircase, with a mirror at the top. The floor is laid with a wood deck and the pillaring has



Arrangement of Accommodations on Boat Deck

the arms of individual Canadian provinces in each of its ten panels. In the after skylight the panels have motives representing British Columbia industries.

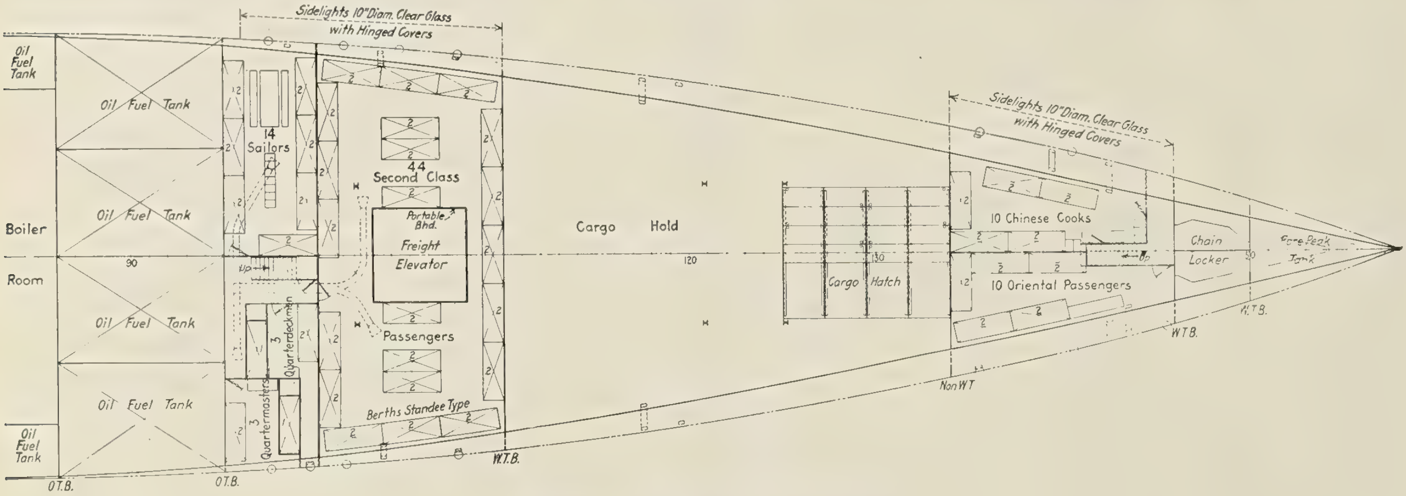
All the balustrades are of wrought iron, with small gilded rosettes in the center for decorative effect.

There are two stairways leading to the awning deck, which is the main passenger deck, containing altogether sixty cabins, twenty-two of which have a sofa berth in addition to the two Pullman berths.

On this deck are also four suites de luxe, each with an individual toilet, and a bathroom common to two. Between been so arranged as to give space for dancing. All around the sides are upholstered arm seats.

All of this deck, aft of the forward social hall is laid with linotile of varying designs. Aft is the stairway to the dining saloon, located on the main deck below surrounded with wrought iron balustrades while on either side are the writing rooms and sitting rooms, respectively, each framed in mahogany.

The main deck forward contains the firemen's quarters, mail room, freight space with its large ports and freight elevator. Amidships are the engineers' quarters, second class



Forward Orlop Deck Arrangement

each suite there is an alcove containing a folding berth with swinging doors, such that the alcove can be made part of the room or a passage between the suites. One suite is framed in bird's-eye maple and its neighbor in satin walnut. On the opposite side of the vessel the two suites are finished in tapestry panels with handsome stucco floral moldings. Each suite has a double brass bedstead, dressing table and wash basin with mirror set in the panelling.

Forward on this deck is the main entrance, beautifully framed in walnut with the floor covered with linotile of tasteful design. The fairweather doors have small glass smoking and dining saloon, crew's mess, bakery and butchery and cold storage rooms. Aft are the galley and dining saloon. The galley is very completely equipped and is entered from the dining saloon by two leather covered swing doors.

The dining saloon, with tables to seat one hundred and forty is framed in natural oak, with a shelf at the sides. At the after end is the sideboard with mirror and cabinets, with leaded glass doors. At the forward end is a handsome screen, with its swinging doors shutting off the staircase. The upper half of this screen is framed in leaded glass.

Underneath the staircase is the silver locker with a very complete layout of drawers and shelves. The side ports are 16 inches in diameter and are arranged in couples. The floor is laid with black and white linotile squares.

The orlop deck, in addition to freight spaces, contains the second class accommodations and crew's quarters.

One very noticeable feature in connection with the comfort of the travelling public is the fact that a hot and cold water system has been installed throughout the vessel, each cabin having a basin with a hot and cold supply. The baths have also a cold salt supply.

In connection with safety appliances it may be mentioned that the boats are swung on Steward davits, this being the first Canadian Pacific Railway vessel to be so equipped.

Propelling Machinery

The propelling machinery consists of one set of four cylinder triple expansion engines, balanced on the Yarrow-Schlick-Tweedy system, designed to develop 4,500 indicated horsepower, at full speed. The cylinders are 28, 43, 50 and 50 inches diameter with a common stroke of 39 inches.

The cylinders are all separate castings and are fitted with liners, the spaces between the liners and the bodies being utilized as steam jackets. The bedplate is cast in two sections and bolted together at about the middle of the engine.

The crank shaft is built up in two sections, one section carrying the forward low pressure and high pressure cranks, and the other the intermediate pressure and after low pressure cranks, the two sections being connected by solid flanged couplings.

The propeller is built up, having manganese bronze blades and a cast steel boss.

Steam is supplied at 180 pounds per square inch by four Scotch marine boilers, each 16 feet in diameter by 12 feet long and having 3,340 square feet of heating surface. The boilers are operated under a closed stokehold system, air being supplied by two engine driven fans.

Oil fuel is used, a pair of horizontal duplex pumps drawing the oil from the bunkers, through suction strainers, and discharging through a battery of heaters and discharge strainers to the furnaces. The furnaces have a ring of fire brick inside the fronts and a hanging arch at the back end. The combustion chambers are also fitted with a checkerwork brick wall.

Auxiliaries

The condenser has a cylindrical steel shell made of one piece of plate with the end bars welded on and with the longitudinal seam electrically welded. The tubes are of Admiralty mixture and are packed at both ends with corset lacing secured by shoulder ferrules.

Cooling water is circulated through the condenser by an independent centrifugal pump driven by an open engine.

To draw the condensation and air from the condenser a Dual air pump is provided, fitted with a cold water circulating arrangement to reduce the density of the vapor.

A pair of vertical simplex pumps take the feed water and discharge it through the filter and feed water heater to the boilers. The feed water heater is of the surface type and is supplied with exhaust steam at 5 pounds pressure. Each feed pump is large enough to supply the boilers when running at full power.

Other auxiliaries include the general service, ash ejector, ballast and cold and hot fresh water pumps. The latter circulates hot fresh water to all wash basins in the vessel.

The electric generating plant consists of two 63 kilowatt 110 volt dynamos, each driven by an enclosed forced lubrication compound engine.

A small CO_2 refrigerating plant is located in the shaft tunnel.

Steam and exhaust piping in the machinery space is in general of solid drawn copper. The main and auxiliary steam pipes from each boiler are extra strong lap welded steel pipe with the pipe expanded into forged steel flanges. All steam and exhaust piping is covered with efficient insulation. The bilge and ballast piping is cast iron with lead bends, except in the stokehold where the bends are extra strong lap welded steel, the extra strong pipe being provided to compensate for corrosion.

Oil fuel piping is lap welded steel with pressed steel flanges. At all distribution points in the piping manifolds are provided.

The boilers were built by the Vulcan Iron Works, Ltd., of Vancouver, while the main engines and practically everything in the engine room, except the auxiliary machinery, were built in the yard's own shops.

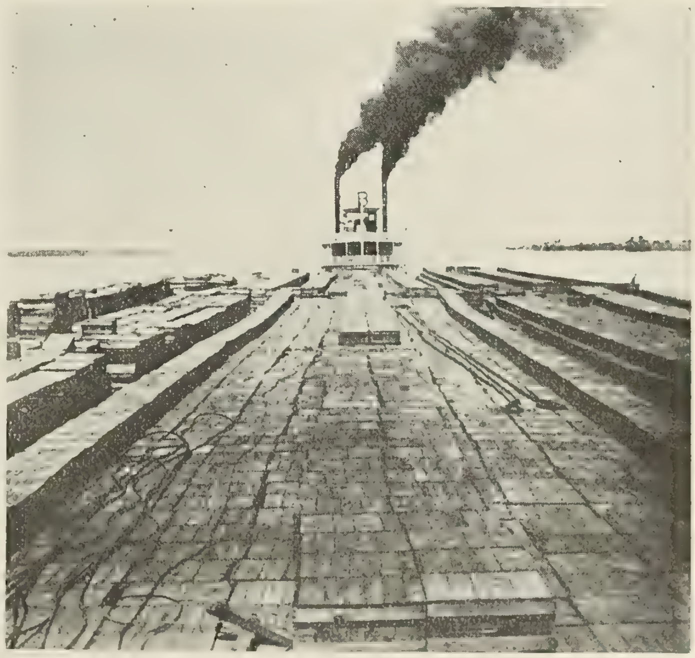
Trials

During the trials the machinery ran exceptionally well. Opportunity was taken during the run from Vancouver to Esquimalt Dry Dock to get everything worked in. The care taken during construction was amply repaid on the trials as there was no sign of heating at any of the bearings.

The balance was also all that could be desired as at the highest rates of revolution the slight athwartship rocking, which is charactereistic of this type of engine, was not apparent.

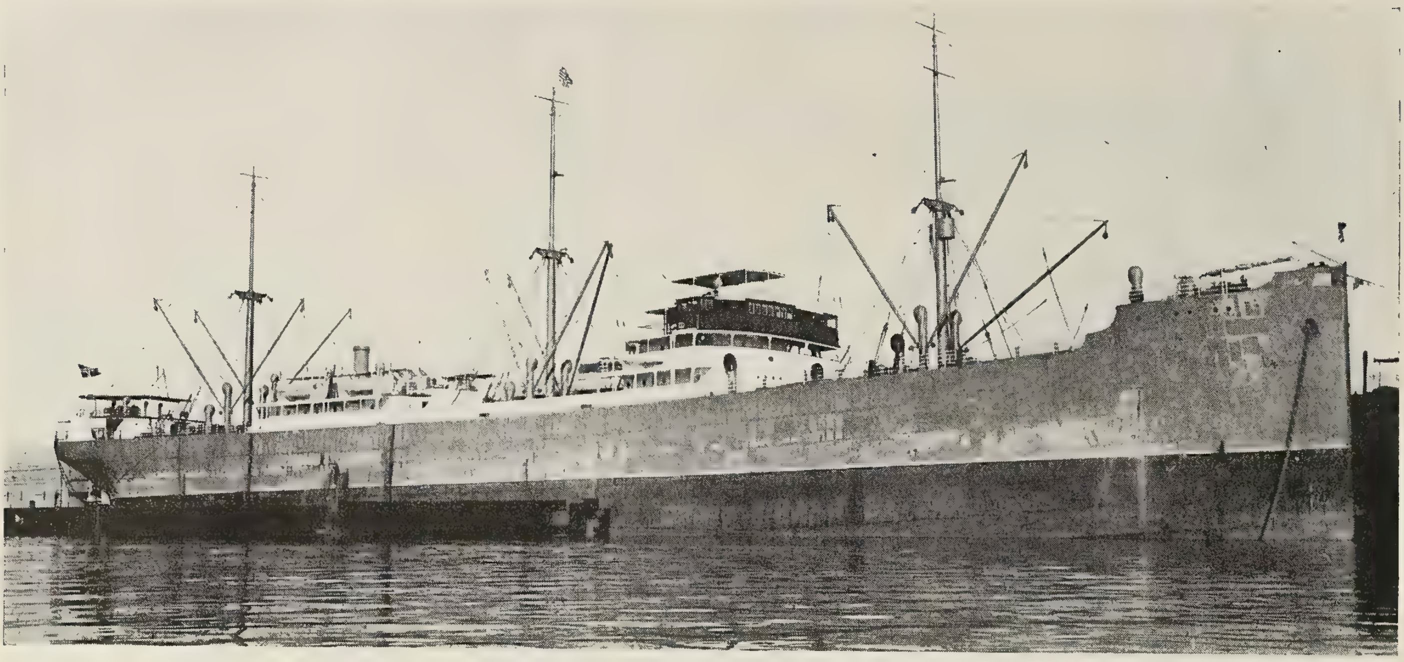
The trials consisted of an endurance run of about four hours' duration at the rate of revolution required to give the contract speed of 16 knots. This was carried out without trouble and steam was easily maintained. The progressive trial was a series of runs, in pairs, over the Parry Bay measured mile. Commencing at 12 knots the speed was increased in steps of about 1 knot until a maximum of 17.48 knots was obtained.

So far as the builders are aware the main engines for the *Princess Louise* are the largest marine engines, and also the first balanced, four cylinder triple expansion engines, which have been built in Canada.



Mississippi River Steamer Handling a 5,000-Ton Tow

The illustration shows the Mississippi River steamer *Mamie S. Barrett*, of the Barrett Towboat Company, Cairo, Ill., towing six barges loaded with approximately 5,000 tons of cargo from the head of the Ohio River to New Orleans, La. The *Mamie S. Barrett* is propelled by a pair of compound engines built by the Charles Barnes Company, Cincinnati, O. The diameter of the high pressure cylinders of these engines is only 10 inches and the fuel consumption is approximately 2½ tons of bituminous coal in 24 hours. Considering the power of the vessel and its small consumption of fuel the volume of tonnage handled is remarkable.



Motorship Handicap Loading Case Oil at Port Arthur, Tex., for China

9,000-Ton Deadweight Norwegian Motorship Handicap

Description of Novel Features and an Analysis Showing the Advantages of the Motorship Over the Steamer

By Edward B. Pollister

On May 15, 1922, the motorship *Handicap* arrived at Port Arthur, Texas, in ballast from Hamburg, and loaded a full cargo of Texas Company case oil for China. The installation of Sulzer two cycle Diesel marine engines was inspected by several marine engineers and representatives of eastern shipowners and shipbuilders, who were interested in the many novel features presented for the first time in the adaptation of the Diesel engine to cargo ship propulsion.

In the latitude of Port Arthur, Texas, the engine room of the *Handicap* with its highest recorded temperature in the tropics of 108 degrees Fahrenheit, was found to be cooler than on deck.

Captain Gustav Sundaa and Chief Engineer Holms extended every courtesy to the visitors.

The *Handicap,* the largest vessel (steam or motor) ever built in Norway, has fine lines and an attractive appearance. Including bunker fuel, she has a deadweight capacity of 9,000 tons on summer freeboard. The ship was constructed by Rosenberg Mekaniske Verksted, at Stavanger, for Messrs. Bruusgaard Krosterud and Company, of Drammen, to the highest class in Norske Veritas (the Norwegian Register) and according to the rules and regulations of the Norwegian Board of Control.

The *Handicap* completed her trials December 14, 1921, and left Stavanger on December 24, for Newport, there loading 7,760 tons of coal for Bahia Blanca. No trouble was experienced with the propelling machinery and on arrival at Bahia Blanca she maneuvered under her own power and did not require the help of a tug.

Performance on Maiden Voyage

Stavanger to Newport	980 miles
Newport to Bahia Blanca	6,390 miles
Mean speed of ship	10¾ knots
Total daily fuel consumption	9.4 tons
Total daily lubricating oil consumption	24.3 gallons
Return voyage—Bahia Blanca—Hamburg	6,943 miles
Mean speed	10 knots
Total daily fuel consumption	10.2 tons
Total daily lubricating oil consumption	22.2 gallons

The *Handicap* sailed from Bahia Blanca with a full cargo of grain, encountering strong winds and heavy seas throughout the whole voyage to Hamburg. Heavy storms were encountered on April 3 and 4, which reduced the speed of the ship at times to 8¾ knots.

The fuel consumption includes not only the fuel used for the main engines, but also that necessary for the auxiliary engines supplying current to the motors for the turbo blowers for lighting, heating, cooking, steering gear and auxiliary machinery.

Dimensions and General Particulars

Length, between perpendiculars	415 feet
Beam, molded	54 feet 6 inches
Depth, molded to shelter deck	36 feet 11 inches
Deadweight capacity, about	9,000 tons
Gross tonnage, about	5,200 tons
Speed, fully loaded	11 knots
Fuel consumption, per day	9.3 to 9.5 tons
Main engines, twin screw	2,700 shaft horsepower
Type	Sulzer, 2 cycle, controlled port scavenging
Number of cylinders per engine	4
Cylinder bore	600 millimeters (23⅝ inches)
Piston stroke	1,060 millimeters (41¾ inches)
Speed	100 revolutions per minute
Auxiliary engines	two, each of 330 brake horsepower
Type	Sulzer, 2 cycle
Speed	210 revolutions per minute
Total weight of main engines, including thrust bearings, flywheels, turbo-blowers, with motors, exhaust silencers, starting and injection air tanks, about	752,400 pounds

Captain Sundaa (center) on the Bridge of the Handicap

Deck View of Motorship Handicap, Looking Aft

Weight per brake horsepower of main engines..........278 pounds
Total weight of auxiliary engines, without electric generators, but with flywheels, silencers and air tanks ....136,400 pounds
Weight per brake horsepower of main engines........50.5 pounds
Total weight of main and auxiliary engines, per brake horsepower of main engines.......................328.5 pounds

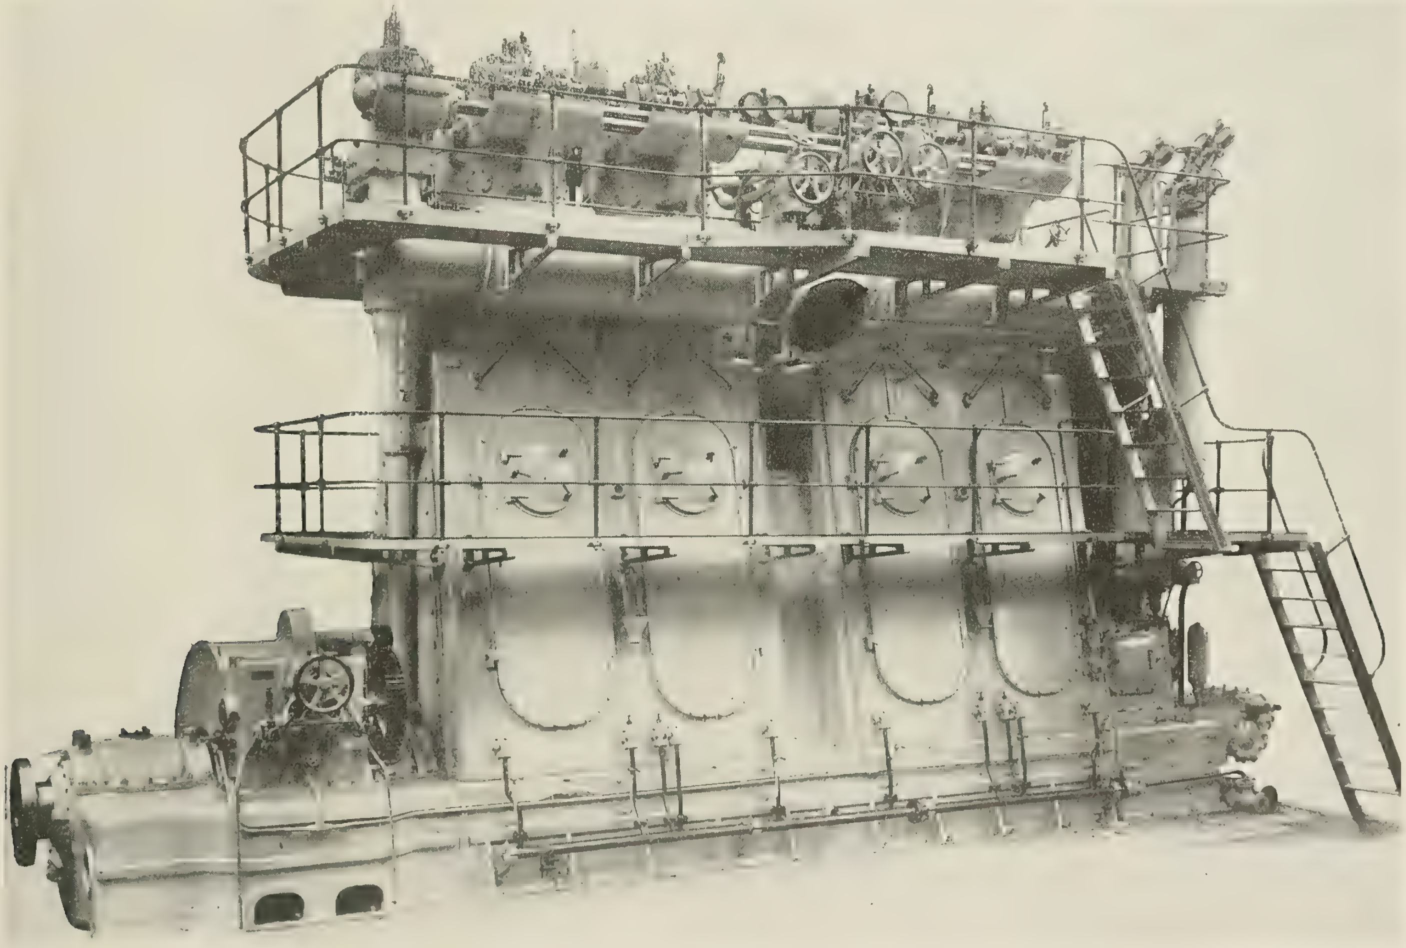
Main Engines

The main engines have four working cylinders, 23⅝ inches diameter and 41¾ inches stroke, with the injection air compressor built integral with the engine. Air for scavenging is furnished by electrically driven turbo-blowers. The visitor is at once impressed with the short length of the engine room (about 40 feet) which this arrangement makes possible. The maneuvering station is located at the upper engine platform, Chief Engineer Holms being strongly in favor of this arrangement, which gives the operating engineer an unobstructed view, at the cylinder head level, of the entire engine room, including valve gear and switchboard. An assistant on the lower grating handles the auxiliaries.

The engines are capable of being operated continuously at maneuvering speeds as low as 25 revolutions per minute and require a comparatively small quantity of injection air under such conditions due to the Sulzer control of lift and duration of opening of the fuel valves.

The Sulzer thrust block, built as an extension to the main bedplate, is similar in principle to the *Kingsbury* type. It is lubricated from the lubrication system on the main engine and showed practically no wear.

The general design of the engines is similar in all important features to the Busch-Sulzer marine Diesel, built by Busch-Sulzer Bros.-Diesel Engine Company, St. Louis,



Sulzer, Two-Cycle, Marine Diesel Engine Designed to Develop 1,350 Brake Horsepower at 100 Revolutions per Minute With Independently Driven Scavenging Pump

Mo., which enjoys partnership affiliation with Sulzer Bros., of Winterthur, Switzerland, and which owns all United States rights and patents for the manufacture and sale of Sulzer engines in this country. Space will, therefore, not be taken here for a technical description of the main engines.

Turbo-Scavenging

Although Sulzers have furnished numerous large submarine installations in which the scavenging air for the engines is supplied by electrically driven turbo-blowers, instead of by scavenging pumps built integral with and driven by the main engines, the *Handicap* is the first commercial vessel so equipped. There are two blower sets, each of capacity for both main engines, one acting as spare. The two sets are located on the level of the control station at the forward engine room bulkhead, one on the starboard and one on the port side, in compartments closed off from the main engine room by doors, the motor blower set requiring about 7 feet by 8 feet floor space. They occupy no part of the engine room which would be otherwise utilized, and the air piping is carried beneath the gratings to the engines in such a manner as to avoid obstructing any passages and yet to be readily accessible from below. The air may be taken from the deck above, or from the engine room floor level to assist ventilation in hot climates. This results in a remarkably cool engine room, the main floor level not exceeding 86 degrees Fahrenheit when passing the equator, although the temperature at the control station was about 108 degrees Fahrenheit.

The blowers are operated at 2,800 to 3,400 revolutions per minute, by 220 volt, direct current motors, without vibration or excessive noise. It has never been necessary to shut down a blower due to faulty operation, and absolutely no trouble has been experienced with these sets. The commutators on the motors were smooth, and an entire absence of sparking at the brushes was noticeable. The power required for the blowers is about 4 percent of the power of the main engines during normal operation.

No Steam Used

On the *Handicap* the use of steam is entirely eliminated. The cabins are heated by electric radiators and the galley is fitted with electric range, electric boilers and an exhaust-gas oven.

The exhaust gases from the engines, at a temperature of about 700 degrees Fahrenheit, are led around an oven which affords a baking heat of 300 degrees to 500 degrees Fahrenheit, attained without additional fuel cost and sufficient to bake the bread for a crew of 35, when the main engines are running. In port, the oven of the electric range is used.

Auxiliary Diesels

The auxiliary Diesels are larger than are usually found on motorships of this size, but are more efficiently employed. The number of auxiliary units has been reduced to the minimum of two—each capable of handling maximum requirements, and consisting of a four cylinder, 330 brake horsepower Sulzer two-cycle crosshead type Diesel, coupled to 200 kilowatt, 220-volt generators, operating at 210 revolutions per minute. The length of the engine is about 13 feet.

At sea, one of these units supplies electric power for the turbo-blower set (about 110 brake horsepower), the engine room pumps, auxiliaries, and steering engine, and current for lighting and heating the cabins and for cooking. The total load at sea averages about 200 brake horsepower.

In port, one unit takes care of the maximum requirements of 10 electric winches of the Asea type, built in Sweden, and the lighting, heating, cooking and small engine room auxiliaries.

This arrangement accordingly results in the auxiliary Diesel capacity, required for winches in port, being largely employed at sea in driving the turbo-blower supplying scavenging air to the main engines, which may therefore be built smaller and shorter. The total weight of the equipment is reduced and the load factor on the total brake horsepower of main and auxiliary engines is increased.

A hot bulb emergency lighting and compressor set provides 15 kilowatts capacity for port lighting, when the winches are not in use.

Elimination of Auxiliary Air Compressors

The air compressors of the two auxiliary Diesels are oversize; their combined excess capacity is sufficient for driving

22—Emergency lighting set (8-kilowatt)
23—Barring engine
24—Reversing engine
25—Switchboard for emergency set

one main engine, which provides the required reserve compressor capacity for emergencies. This saves the installation of the usual motor driven auxiliary compressor of about 150 brake horsepower for this size of vessel.

The surplus air is used for charging the starting and maneuvering air tanks of which there are eight, each having a capacity of 28 cubic feet at 60 atmospheres.

Air at any pressure from 60 to 20 atmospheres (850 to 285 pounds per square inch) is utilized for starting and maneuvering, the high pressure storage providing ample reserve capacity for extensive maneuvering on entering port.

A large supply of low pressure air, 200 pounds per square inch, is carried in separate tanks for the operation of the maneuvering motors on the main engines, the turning engines, the siren and for minor purposes, including small auxiliary lubricating pumps used before starting up.

Captain Sundaa, who "went down to the sea" as a cabin boy on a windjammer at the age of fourteen, accepts the motorship in the same spirit that he was forced to accept the steamer, years ago—one of reluctance, tempered with a desire to be first with a new type of vessel which was bound, in his opinion, to replace the old.

Telling the story as nearly as possible in the captain's words: "The engines run quietly, without sufficient vibration to tell, from his cabin, whether they were running or shut down. Cylinder heads were being removed for the first time in five months, to meet provisions of semi-annual inspection required by the Norwegian Board of Control. Aside from minor grinding of valves and adjustments, no repairs had been necessary, the cylinders and combustion chamber parts were clean and the wear of rubbing surfaces extremely small."

So far the ship had given a good account of herself, the only stoppage at sea having been due to air pockets in the fuel line, on a voyage to South America, and a safety gasket blowing out on the trip from Hamburg to Port Arthur.

Important Advantages of the Motorship Over Steam in Addition to the Fuel Saving

The fuel consumption of the *Handicap* is only 9.3 to 9.5 tons a day, for 11 knots, as against 30 tons for a steamer. Only 3 men, namely a motorman, a junior motorman and an oiler, are required on a watch in the engine room, two electricians, two wiper boys and a mechanic bringing the engine room crew up to 14.

But other advantages of the motorship over the steamer are of far-reaching importance and not always given due consideration.

The investment in a ship over a twenty-year period is safeguarded more securely by low cost of operation which prevents losses in bad times, than by expectation of big profits in good times.

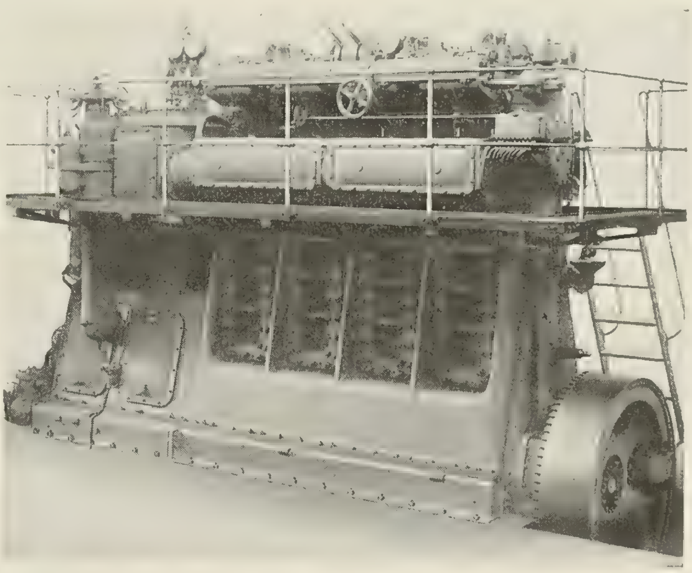
The motorship will average more days at sea, which is the only time a vessel earns money. With approximately 1/3 of the fuel consumption of a steamer, less time is lost in fueling enroute, or in deviating for fuel with additional cost of port charges. More freight can be carried, at rates below the cost of operating a steamer, if necessary for quick return freight. Long voyages can be undertaken to ports where fuel is scarce or high, bunkered with fuel sufficient for the complete turn-about and bought where it is cheapest. The motorship also can, with profit, collect small scattered freight which would be unprofitable for a steamer. The steamship must also secure more freight to pay the higher operating expenses of a return voyage, and this waiting in port cuts down the number of days per annum she will be at sea with profitable freights. While in port, the standby losses of the steamer are, comparatively, very high and, where lack of up-to-date dock freight handling apparatus causes delays of several days, the cost of handling cargo at 6 tons of fuel per day for the steamer as against 0.6 ton for the motorship becomes an important item.

These advantages are illustrated by the present voyage of the *Handicap*.

A full cargo of case oil was offered for China, from Port Arthur, Texas, each case stowing 2.2 cubic feet, weighing 84 pounds, 26.7 cases to the ton, freight rate about $9.00 per ton.

For the outward voyage (about 10,000 miles)—39 days at sea, 11 knots, 9.5 tons per day—370 tons of fuel will be burned, and, with 25 percent reserve, 465 tons carried—without refueling enroute.

With a deadweight capacity of 9,000 tons, including fuel, the maximum cargo which could be loaded at Port Arthur was 8,535 tons, or 228,000 cases. A corresponding steamer must allow bunker capacity for the longest leg—Honolulu to



Sulzer Two Cycle Auxiliary Diesel Engine. Develops 330 Brake Horsepower at 210 Revolutions per Minute

Hongkong, 4,900 miles—19 days at 11 knots, 30 tons of fuel per day, 570 tons burned; plus reserve of 25 percent requires a minimum bunker capacity of 715 tons; thus the maximum cargo which could be loaded at Port Arthur would be 8,285 tons, or 221,000 cases.

Difference in Favor of Motorship

1—Additional freight, 250 tons @ $9.00			$2,250.00
2—Steamer must deviate from Canal to Honolulu additional mileage—1 day's run—fuel @ 30 tons per day @ $7.80			234.00
3—Port charges—Honolulu, including towing and pilotage			250.00
4—One day additional operation of ship, exclusive of fuel			150.00
5—Outward voyage:			
Fuel burned by motorship, Port Arthur fuel, 370 tons @ $9.80		$3,615.00	
Fuel burned by steamer:			
Port Arthur fuel 600 tons @ $7.80	$4,680.00		
Honolulu, fuel 570 tons @ $9.25	5,275.00	9,955.00	6,340.00
6—Return voyage:			
Fuel burned by motorship, Hongkong fuel, 370 tons @ $17.60		$6,500.00	
Fuel burned by steamer:			
Hongkong fuel, 570 tons @ $15.60	$8,850.00		
Honolulu fuel, 600 tons @ $9.25	5,550.00	14,400.00	7,900.00
Port charges—fueling at Honolulu			250.00
1 day additional sailing—30 tons fuel @ $9.25			275.00
1 day additional operating expenses exclusive of fuel			150.00

7—Loading and discharging cargo—20 days fuel:		
Motorship—Port Arthur 10 days @ 0.6 ton @ $9.80	$59.00	
Hongkong 10 days @ 0.6 ton @ $17.60	105.00	
	$164.00	
Steamer—Port Arthur 10 days @ 6 tons @ $7.80	$468.00	
Hongkong 10 days @ 6 tons @ $15.60	936.00	
	$1,404.00	1,240.00
Total excess cost of operation of steamer		$19,039.00

Earnings of the Steamer

Earnings of the steamer—8,285 tons @ $9.00		$74,565
Round trip, returning in ballast 100 days		
Estimate:		
Operating expense, except fuel @ say $150.00 day	$15,000	
Panama tolls @ 2 x $6,000	12,000	
Fuel	26,268	
2 calls Honolulu, port charges	500	53,768
100 days steamer's gross earnings		$20,797

Earnings of the Motorship

Earnings of the motorship—8,535 tons @ $9.00		$76,815
Round trip, returning in ballast 98 days		
Estimate:		
Operating expense, except fuel at $150.00 day	$14,700	
Panama Canal tolls @ 2 x $6,000	12,000	
Fuel	10,272	36,972
98 days motorship gross earnings		$39,843
365 days motorship		$147,000
365 days steamer		76,000
Additional gross earnings of the motorship		$71,000

Ratio of Earning Capacity—Motorship to Steamer—Is 1.93 to 1

In the above figures a differential of $2.00 per ton has been assumed for Diesel fuel above the price of boiler fuel —which is applicable to all motorships and fair to the 2-cycle, until the claims of the 2-cycle marine Diesel builders, that operation of their engines on boiler fuel is entirely satisfactory have been more definitely established.

Advantages of the greater sailing radius of the motorship and increased earnings due to purchase of fuel in that port where it is cheapest have not been taken into consideration.

It is reasonable to assume that the reduction in the payroll of the engine room crew will more than offset the increased cost of lubrication for the Diesel.

That the rate of depreciation of the steamer is greater than the motorship is shown by the present market price of going steamers, which is less than one half their book value; while practically no going motorships are offered.

The above figures assume steady trade and no idle time, which, of course, would not be the case. If it were, the motorship could cut freight rates sufficiently to wipe out the profits of the steamer and still show gross earnings of $71,000.00 per annum.

As a matter of fact, the $76,815.00 freight money earned by the *Handicap* on her China voyage must pay her expenses from Hamburg in ballast to Port Arthur—Port Arthur to China, and from time of discharge of cargo at Hongkong until she secures another cargo. So that the actual earnings for the year will not be as shown.

That the actual saving is greater than that usually estimated is shown by the growth of motorship fleets—the aggregate of all of the economies and advantages of motorships being best known by their owners.

While a tramp run to the Orient is especially favorable to the motorship, other runs such as Pacific Coast to United Kingdom ports—a turnaround of 25,000 miles, offer almost equally favorable conditions for freight liners.

A steamer, loading deadweight cargo on the Pacific Coast, must hold in reserve sufficient bunker capacity for fuel from the Canal to the United Kingdom, a run of about twenty days. With the differential of 20 tons per day for the above ships, plus 25 percent reserve, 500 tons more cargo could be carried by the motorship at say $12.00 per ton or $6,000.00. On arrival in England, fuel must be purchased at say 60 shillings ($13.50) per ton for port use, and the return voyage to New York—approximately three times as much fuel must be purchased at this comparatively high price, for the steamer as for the motorship.

Considering the progress the motorship is making in the world's merchant marine, the probable obsolescent decline during the next few years in the value of a steamer reduces the comparative fixed charges on the motorship by between 5 and 10 percent and offsets to a degree the added cost of converting existing steam tonnage.

This would be shown by the above figures on earnings, somewhat as follows:

	Motorship	Steamer
Tonnage, deadweight	9,000	9,000
Gross earnings	$147,000.00	$76,000.00
Fixed charges	15 percent	20 percent
(Allowing 5 percent greater depreciation in value of steamer)		
Investment basis, total	$980,000.00	$380,000.00
Investment basis, per ton	$108.80	$42.20
Present sales value going steamer per deadweight ton world's market		$35.00
Corresponding value of motorship on above investment basis	$90.00	

The United States Shipping Board is offering steamships for conversion to Diesel propulsion at prices which will bring the cost of the motorship to about $75.00 per deadweight ton, a price which shipowners would be fully justified in paying, considering the above comparative earnings.

Argentine Naval Training Ship Presidente Samiento Anchored in North River, New York

Japanese Channel Steamer Keifuku-Maru on Trial

Twin-Screw Turbine Channel Steamer Keifuku-Maru

First of Three 17¼-Knot Passenger Vessels for Shimonoseki-Fusan Service of Japanese Government Railway Completed at Kobe

THE cross-channel service between Shimonoseki and Fusan in Japan is at present run by the Japanese Government Railway with a fleet of four steamers, the *Koma-Maru, Shiragi-Maru, Iki-Maru* and *Tsushima-Maru,* performing the journey in more than eleven hours. Owing to the recent increase of traffic on this route, it was decided in 1920 by the Railway Department to reinforce the existing fleet with three larger and faster steamers of the latest improved type.

The order for these new ships was placed with the Kobe Works, Mitsubishi Zosen Kaisha, Ltd., Kobe, Japan. The first of the three steamers has recently been completed and delivered to the owners. In their arrangement and equipment, every attention has been paid to the special requirements of this service, and in this respect mention must be made of the work of Mr. T. Morisawa, the marine superintendent to the Government Railway, and his staff, under whose supervision on behalf of the Railway Department the vessel has been completed, while the design of both hull and machinery was entirely entrusted to the builders to fulfill the requirements of the owners.

The leading particulars of the *Keifuku-Maru* follow:

Length overall	375 feet 0 inches
Breadth, molded	46 feet 0 inches
Depth, molded to awning deck	28 feet 0 inches
Gross tonnage	3,620
Draft loaded	15 feet 0 inches
Deadweight capacity, in tons	600
Number of passengers:	
First class	45
Second class	214
Third class	690
Total number of passengers	949

Palm Room Cafe

Smoking Room

Number of officers and crew	159
Total number of passengers and crew	1,108
Highest speed on trial	20¼ knots
Speed on service	17¼ knots

The *Keifuku-Maru* has been built, engined and equipped in accordance with the Japanese Government Shipbuilding and Inspection Rules under their special inspection as an awning deck vessel of coasting service.

General Arrangement

As shown by the illustrations, the vessel has a short forecastle with a raked stem, cruiser stern, two masts and two funnels.

The double bottom, built on the cellular principle, extends between the peak bulkheads, except under the boiler space. The vessel is subdivided by six transverse watertight bulkheads, all extending to the main deck except the collision bulkhead which is carried up to the awning deck.

Special Sitting Room

There are two complete tiers of decks, viz., the awning and the main, and a promenade deck over the long deck house amidships, a lower deck and a flying bridge deck.

The promenade deck is mainly allotted for the promenade of the first and second class passengers. On this deck forward are the captain's and the officers' cabins and toilets and the special suite of rooms, consisting of a sitting room, bedroom and private bathroom, and a first class stateroom.

The smoking room and palm café are also situated on this deck between two funnels.

Ten lifeboats and one sampan are carried on this deck aft.

The awning deck is almost entirely occupied by the passenger accommodations, the first class staterooms being amidships, the second class sleeping rooms and open space aft. The restaurant and the reception and writing rooms are also on this deck forward of the first class accommodations, and the sailors' quarters are under the forecastle.

On the main deck are part of the third class passenger accommodations and accommodations for the engineers, clerks, doctors, custom officers, etc., the officers' and engineers' messrooms, galleys, sculleries, pantry and stores. There is also a large mail room on this deck forward.

The lower deck abaft the engine space is arranged for the remaining third class passenger accommodations and the baggage room, steering engine space and carpenter's store.

The firemen's and the boys' quarters are located on the lower deck forward of the boiler space, the space below being devoted to a cargo hold. In the forehold are a fish hold, provision stores and the chain lockers.

Passenger Accommodations

Excellent results have been achieved in fitting out the passenger accommodations on the *Keifuku-Maru,* and particular attention has been paid to ensure the comfort and pleasure of passengers consistent with the requirements of a short passage.

The public rooms include a smoking room, palm café, restaurant, and reception and writing room, all of which are tastefully decorated and furnished.

The smoking room is finished in stained oak in the Elizabethan style. A large wagon top skylight with attractively designed stained glass and large square windows admits air and light. A bar with counter is provided at the forward end of the room. The floor is laid with rubber tiling of special design well matched to the room.

A special feature of the palm café, adjacent to the after end of the smoking room, is the striking originality of its design, giving passengers the impression of sitting in a greenhouse on shore. The specially designed windows of exceptional size and a large stained glass skylight aid materially in lighting and ventilating the room. The walls are finished in green trellis work on braided rattan ground over marble skirting, and four artistic oval cloisonné plaques and a large oval mirror are attractively arranged. The floor is covered with rubber tiling of chess-board pattern in dark green and white.

At the after end of the palm café, there is a grand stairway leading to the main entrance on the deck below, which is finished with handsome balusters and hard wood rails. At the head of this stairway is mounted a large oil painting depicting "A country scene of Chosen (Korea)" by Mr. H. Kanayama.

A spacious and airy restaurant, situated at the forward end of the awning deck house, is framed in Nara (a kind of oak) with silk panels over dado of polished Nara. The ceiling is panelled and painted in dull white. A stained glass skylight and glass mosaic plaques are fitted overhead.

A number of small tables accommodating parties of four and one larger table for six in front of the bay-windows on each side are arranged. An imitation fireplace at the forward end adds a homelike touch to the appearance of the room. Surmounting the fireplace is an artistic picture of cut-velvet representing the garden scene of the Keifuku palace. The floor is of neatly designed rubber tiling.

The reception and writing room adjacent to the after end of the restaurant is reached through stained glass swinging doors on each side. The room is tastefully finished with extra large panelling painted in light shade in stained oak framing, decorated with a number of carved relieves. The writing tables, seats, tea tables and chairs, all well harmonized to the room, are comfortably arranged. The floor is covered with rubber tiling.

The special suite of rooms previously mentioned is arranged entirely separate from the ordinary first class accommodations. The sitting room is finished in fumed oak with panels of silk damask. The ceiling is plain but tastefully treated, having ornamental fixtures. A picture of silk embroidery representing resting lions is hung on the wall. The special bedroom is furnished with a large bedstead, dressing table, wardrobe and chair, all of which harmonize with the joiner work of the room. The floors of these rooms are covered with thick carpets.

Effective ventilation for the third class accommodations is provided by means of motor fans.

The electric lighting throughout is on an extensive scale, all fixtures fitted in the public rooms having been designed to harmonize with the general scheme of decoration and architecture.

Propelling Machinery

The propelling machinery consists of two sets of Parsons combined impulse and reaction, geared turbines of the modern high speed type. Each set drives one of the twin propellers through a single reduction gearing.

The machinery is designed to develop 8,000 shaft horsepower. Each set consists of two turbines arranged in series, with one high pressure turbine inboard, and one low pressure turbine outboard. The high pressure turbine has one impulse stage and 5 reaction stages of 7 rows each. The low pressure turbine has 11 stages with 22 rows in all. Astern turbines are incorporated in the forward end of the low pressure turbine casings, capable of developing about 60 percent of ahead full power.

A forced lubrication system is provided for all bearings, gearings and shaftings. The main thrust bearings are of the single collar pivoted type.

Boilers

Steam is supplied by 8 cylindrical marine boilers, designed for a working pressure of 200 pounds per square inch and superheat up to 120 degrees F. The boilers are arranged in two groups of four each with two stokeholds. Forced draft is provided by a closed ash-pit system.

The results of the official trial trip were highly satisfactory, extracts of which are shown tabulated as follows:

Result of Official Trial Trip

Date of trial	April 1, 1922
Weather and sea	Fine, calm
Draft, forward	15 feet 2 inches
Draft, aft	15 feet 1¼ inches
Draft, mean	15 feet 1⅝ inches
Corresponding displacement	3,940 tons
Speed (mean of 3 double runs on 3-mile measured course)	19.776 knots
Coal consumption per shaft horsepower per hour	1.3 pounds
Boiler pressure, pounds per square inch	200
Steam pressure:	
High pressure turbine, pounds per square inch	167
Low pressure turbine, pounds per square inch	8
Vacuum, inches	28.5
Revolutions per minute of propellers:	
Port	216.83
Starboard	215.66
Mean	216.25

The electrical equipment of this vessel consists of two 2½ kilowatt Winton generating sets, with large type Edison storage batteries. This equipment will be sufficient to take care of all electrically operated, automatic and auxiliary machinery installed in the boat.

The storage space for supplies will be sufficient to enable the vessel to cruise at great distances from her base of supplies. The cold storage plant consists of an ethyl chloride machine of the Clothel manufacture and several boxes, some in the deck house for daily supplies with others below for cold storage.

John Ringling's Houseboat Zalophus, Just After She Was Launched at the Yards of the Builders

The small boat equipment of the *Zalophus* consists of several fast launches swung on the boat deck to be used by the owner and his party to make trips up small rivers not navigable by the larger boat.

Motor Houseboat Zalophus Launched

JOHN RINGLING'S new steel motor houseboat *Zalophus* was recently launched at the yards of the Consolidated Shipbuilding Corporation, Morris Heights, New York City. The vessel was designed by Henry J. Gielow, naval architect of New York, and is powered with two heavy oil Nelseco engines of 180 horsepower each. The approximate combined weight of these engines is 20 tons. The oil capacity is 6,200 gallons, giving the vessel a cruising radius of over 4,000 miles.

The vessel is 125 feet long overall, 21 feet beam and has a draft of 4 feet, capable of cruising in southern waters during the winter months, and in the north in the summer.

The large deck house on the main deck is approximately 86 feet long. At the forward end a living room is arranged with a stairway down to the owner's suite. The dining room, pantry, servants' lounging and dining rooms and pantry follow. The owner's lounge and smoking room are aft. All sleeping rooms in the owner's quarters, baths and toilet rooms are forward, followed by the engine compartment. The after end is given up entirely to the crew's quarters, which are exceptionally complete, as they include staterooms for the engineers and members of the steward's department, toilet rooms and two shower baths, one for the officers and one for the crew. The captain's quarters are arranged at the after end of the pilot house, with a toilet room and shower bath at the after end.

U. S. Grant Has Successful Sea Trial

THE Army Transport *U. S. Grant,* formerly the *Madawaska,* was given a successful sea trial on Sunday, July 16. The *Grant* left Pier 3, Army Supply Base, Brooklyn, at 9.00 a. m. and proceeded directly to sea, cruising south along the New Jersey coast. At the beginning of the trial, the Filipino firemen, whose previous experience had been confined to Scotch boilers, had some difficulty in learning how to fire watertube boilers.

After they had been shown that the thickness of the fuel on the grates should be from 6 inches to 8 inches rather than from 12 inches to 14 inches, as is desirable on Scotch boilers, and that the back of the grates should be well covered, the steam pressure was raised and the ship made from 14 to 15 knots. It is expected that a speed of 15 knots will be easily maintained when the firemen become accustomed to the boilers.

The principal part of the reconditioning job on the *Grant,* which was done by the Morse Dry Dock & Repair Company, Brooklyn, N. Y., was the removal of three double-ended and one single-ended Scotch boilers and the installation in their place of six Babcock and Wilcox type of watertube boilers. These boilers are fitted for burning coal under forced draft with closed ash pits and open fireroom. Fans are fitted under the back ends of the boilers. Diamond soot blowers of the revolving type are installed on each boiler.

Captain A. B. Fry stated in an interview that "240 tons

of weight had been saved in the boilers and contained water by the installation of the watertube boilers. Savings in weight, the confinement of possible explosions to the blowing of single tubes and rapid steam generation had made watertube boilers very desirable for passenger ships when a supply of good feed water could be obtained."

Captain Fry also said that "after a thorough inspection of the old Scotch boilers on this vessel they had come to the conclusion that it would not be safe to operate them at a pressure in excess of 187 pounds per square inch which, in his opinion, would have been reduced to 165 pounds at the throttle. As the *Grant's* engines are of the four cylinder quadruple expansion type it was thought desirable to install new boilers working at 225 pounds pressure which would insure dry steam, with some superheat effect, at 205 pounds at the high pressure cylinder.

The *U. S. Grant* is admirably designed for tropical service, having high tween-deck heights. Two new 15-ton York refrigerating machines have been fitted to insure efficient service in the hottest weather.

This vessel, which is 490 feet long, 55.3 feet beam, 25.7 feet depth and 9,410 gross tons, sailed for San Francisco on July 20 carrying a general cargo of merchandise, passengers and troops. Her capacity is 126 cabin passengers and 600 troops and she will enter the Army Transport Service between San Francisco and the Orient.

Among those present on the trial were the following: Colonel L. H. Bash, Colonel A. C. Dalton, Colonel Thayer, Major Rice, Captain Robbins, Captain Ferrand, Captain Moore, Captain Bernard and Superintending Engineer J. T. Stewart of the Army Transport Service; Captain A. B. Fry, U.S.N.; Major F. Van Vleck, consulting engineer; Captain Paul Cantry of Motor Transport Service; F. B. Webster, editor of Marine Engineering and Shipping Age; C. H. Want and J. M. Dempsey of the Morse Dry Dock and Repair Company; F. W. Leahy and W. Crawford of the Diamond Power Specialty Company; E. A. Colson and R. D. Bryan of the Babcock and Wilcox Company.

Devices Designed to Cut the Cost of Air Drill Operation

The lubrication of air drills is not generally considered as one of the items of shop operation subject to the promotion of economy, yet in plants where such tools are used to any great extent, it is necessary to lubricate them at least once a day and in many cases oftener. Certain drills require 15 minutes to lubricate and others as high as 30 minutes. With this fact as a basis, the Chicago Pneumatic Tool Company, Chicago, Ill., carried out an extensive survey of air drill operating costs, which led to the design of an oil vent to prevent air leakage and lessen the necessity of frequently oiling these tools.

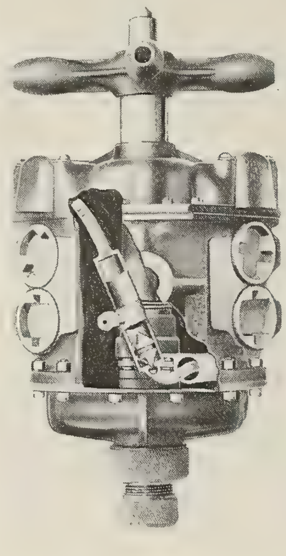
This oil vent is applicable to most sizes and types of "Little Giant" air drills. On new drills it is furnished as regular equipment, and is also attachable to drills now in use. The vent contains a sliding top-shaped plunger which automatically prevents oil leakage regardless of the operating position of the drill.

The estimated saving in time, labor and lubricant based on time and wage factors which are more or less indeterminate is shown by the following comparative figures submitted by the manufacturer:

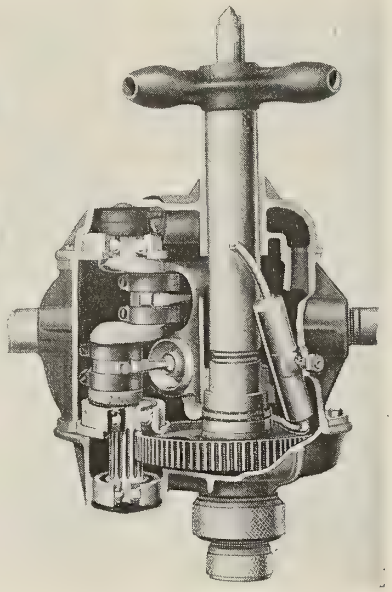
(1)	Grease per day, ½ pound, at 10 cents per pound	$0.05
	Labor per day, ½ hour, at 60 cents per hour	.30
	Total upkeep per day	$0.35
	Total upkeep cost per six-day week	$2.10
	Less one application per week for machine with vent tube	.35
	Net saving per week	$1.75
	Net saving during 52 weeks	90.00
(2)	Grease per day, ½ pound, at 10 cents per pound	$0.05
	Labor per day, ¼ hour, at 60 cents per hour	.15
	Total upkeep per day	$0.20
	Total upkeep cost per six-day week	$1.20
	Less one application per week for machine with vent tube	.20
	Net saving per week	$1.00
	Net saving during 52 weeks	52.00
(3)	Grease per day, ½ pound, at 10 cents per pound	$0.05
	Labor per day, ½ hour, at 50 cents per hour	.25
	Total upkeep per day	$0.30
	Total upkeep cost per six-day week	$1.80
	Less one application per week for drill with vent tube	.30
	Net saving per week	$1.50
	Net saving during 52 weeks	78.00
(4)	Grease per day, ½ pound, at 10 cents per pound	$0.05
	Labor per day, ¼ hour, at 40 cents per hour	.10
	Total upkeep per day	$0.15
	Total upkeep cost per six-day week	$0.90
	Less one application per week for drill with vent tube	.15
	Net saving per week	$0.75
	Net saving during 52 weeks	$39.00

One-Piece Interchangeable Toggle

Another new air drill feature applicable to all "Little Giant" air drills is known as the "Invincible" one-piece interchangeable toggle. The toggle bearing and connecting rod are integral and are secured in place in pairs by means of hinged split collars. It is claimed that this feature provides an opening at the top and bottom of the toggle bearing



Section of Vent Tube on "Little Giant" Air Drill



Vent Tube and One Piece Interchangeable Toggles

which permits the lubricant to come in direct contact with the crank pins. All parts are interchangeable, there being no inside or outside toggle, each being subjected only to the stresses of its own piston. The toggle may be assembled and dis-assembled without dismantling the drill.

Engineers' Employment Service.—An employment service for engineers of every variety of training and experience is conducted by the four National Engineering Societies of the United States. This service brings in touch with the various business men the service of 50,000 trained technical men who are members of these societies. This service is in a position to supply marine, mechanical and designing engineers, trained superintendents and other executives. It is located in the United Engineering Buildings, 29 West 39th Street, New York, under the direction of W. V. Brown and is free to both employer and to employee.

7,500-Ton Motor Tanker Oljaren, Built by Gothenburg Shipbuilding Company for Transatlantic Steamship Company

Motorship Building in Europe

New Type of Double Acting Diesel Engine—New Diesel Electric Ship—A Motor Oil Tanker

By Our Special London Correspondent

SHIPOWNERS in Europe, while admitting the superiority of the oil-engined vessel, are urging manufacturers to produce engines of much lighter construction and lower cost. With this demand in view, a great deal of experimental work has been carried out in various countries with the object of building Diesel or other oil engines less weighty than the existing type and it is a notable fact that the majority of the best-known manufacturers of marine oil engines have recently patented various devices, usually relating to double acting engines on the two cycle or four cycle principle.

A noteworthy development, however, has now been made by the production of a double acting two cycle engine by the North British Diesel Engine Works, a firm which was established for the sole purpose of building Diesel motors. Hitherto they have confined their attention to the four cycle single acting type and machinery of their design was fitted in the passenger liner *Domala*.

They first built an experimental engine of two cylinders designed to develop 240 brake horsepower at 250 revolutions per minute and, having found no troubles, as a result of series of tests they are now constructing a 2,000 brake horsepower three cylinder double acting engine of the same design, which will be installed in a single screw ship.

Scavenging Valves Eliminated and Sliding Cylinders Adopted

At first sight the engine gives the impression of being almost impracticable. The designers started with two main ideas. In the first place they wished to eliminate scavenging valves and to arrange for the scavenging air to pass right through the cylinder from one end to the other. Secondly, they desired to avoid the passage of the piston rod through the lower cylinder cover, since this not only causes trouble with packing glands but also diminishes the output of the engine. They, therefore, adopted the novel idea of having a sliding cylinder and fixed cylinder covers at the top and bottom.

There are scavenging ports at each end of the sliding cylinder, uncovered at the right moment, as the cylinder moves over the cylinder covers. The exhaust ports are in the center, one set for the lower half of the cylinder and one

for the upper. These are uncovered at the correct timing by the movement of the cylinder relative to the piston. There is no piston rod passing through the cylinder cover but the gudgeon pin is taken out through slots in the cylinder on each side and the drive is arranged on to a forked connecting rod, thus giving one crank per cylinder. The fuel is injected centrally through atomizers arranged in the top and bottom cylinder covers, in which are also located starting valves.

It will be seen from this description that not only does the cylinder with its water jacket reciprocate over the cylinder covers (which are provided with piston rings) but also the scavenging and exhaust branches, which move up and down through gas tight joints in the scavenging and exhaust trunks respectively. This would at first sight appear to be a somewhat clumsy system but the builders state that comparatively little power is needed to drive the cylinders and it must be remembered that oscillating cylinders were used with steam engines some years ago with complete satisfaction.

Weight and Space Reduced 50 Percent

The engine operates on the normal Diesel principle with air injection driving its own scavenging pump and air compressor. Some remarkable claims are made. The weight is said to be exactly half that of a corresponding four cycle engine, while the space needed is also 50 percent and is in fact the same as that required for a reciprocating steam engine without the boiler. It is thought that the cost of construction will be materially reduced and the comparative smallness of the set may be gaged from the fact that the three cylinder 2,000 brake horsepower motor now being built has a cylinder diameter of only 24½ inches and a stroke of 44½ inches.

The completion of the trials of this remarkable experimental engine has come as something of a surprise in engineering and shipbuilding circles in Great Britain and very great interest is being shown in the new development. Incidentally, as indicating the activities in the construction of internal combustion engines, it may be added that there is some likelihood of the production of a rotary marine oil engine in the near future.

Diesel Electric Drive

European shipowners have remained somewhat sceptical regarding the advantages of the Diesel electric drive for ships, as the general opinion appears to be that the cost of installation must be greater and the overall economy somewhat lower than with the direct drive. It is noteworthy, therefore, that an order has been placed with Cammell Lairds of Birkenhead for three new 6,000-ton deadweight vessels in which the Diesel electric system of propulsion will be employed. The ships are for the United Fruit Company of Boston, Mass., and will represent something of a novelty in European motorship construction.

It is especially noteworthy that the propelling plant will consist of four generators driven by Cammellaird Fullagar types of oil engine, which is claimed to be the lightest and smallest internal combustion engine on the market. It is, of course, of the opposed piston design, built in units of two cylinders cast together, diagonal links connecting the upper crosshead of one cylinder with the lower crosshead of the adjoining cylinder.

So far as can be judged there will be little difference in the weight of this Diesel electric plant as compared with the direct drive, since the engines driving the dynamos will naturally be of the high speed type and a great saving in weight will be effected. For instance they will probably run at between 250 and 300 revolutions per minute, whereas marine engines of the same total power would have to operate at not more than 100 to 110 revolutions per minute. It should be added, however, that the general impression in Europe is that while the Diesel electric drive has advantages in special cases, it is not likely to find widespread adoption.

A 7,500-Ton Motor Tanker

An increasing number of motor oil tankers are now being constructed and in addition to the oil transport companies, owners of fleets of cargo motorships are building their own tankers in order to render them to a certain extent independent of the oil transport concerns. One of the finest oil tankers recently turned out is the *Oljaren*, which was completed at Gothenburg by the Gothenburg Shipbuilding Company in June. She is for the Transatlantic Steamship Company, and the intention is to use her to carry oil either to Sweden or any other port where the Transatlantic motorships may bunker. She has a deadweight of 7,500 tons, a length overall of 399 feet 3 inches and a depth of 55 feet. The hull is divided into eleven tanks and in the pump room are installed two 250-ton per hour electrically driven pumps and one of 100 tons per hour. The arrangement is such that electric motors are fitted in the engine room and the shafts driving the pumps pass through the bulkhead dividing the engine room from the pump room.

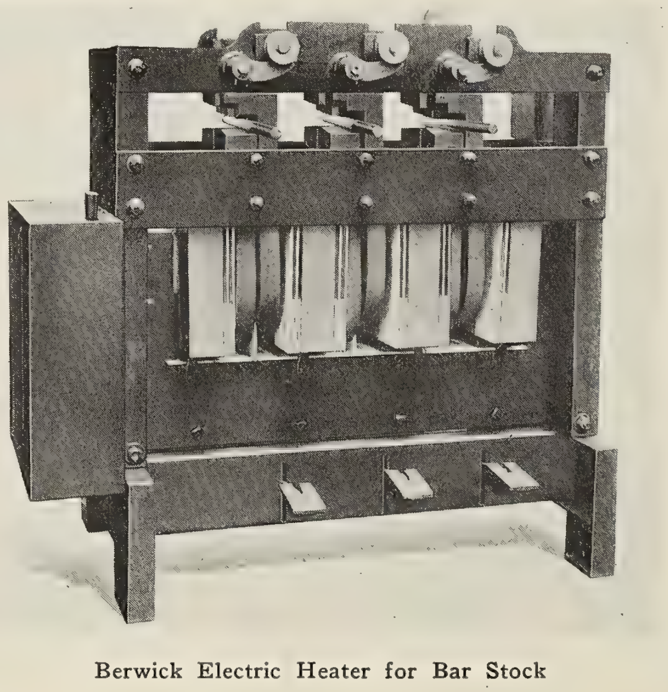
The propelling plant consists of two Burmeister and Wain type oil engines, each of 1,300 indicated horsepower. The auxiliary sets comprise three Diesel driven generators of 75 brake horsepower each driving 50-kilowatt dynamos. All other machinery is electrically operated, but there is a boiler for steaming out the tanks and another for heating the cabins.

The *Oljaren* represents the most modern type of European motor tanker, particularly in the auxiliary arrangement, since it has been customary hitherto to employ steam driven cargo pumps, even in motor tank ships. The daily fuel consumption of this vessel for a speed of about 10½ knots is about 8 tons.

Two Path Electric Heater

A BERWICK electric heater for heating the ends of stock to be used in forging operations has been developed by the American Car and Foundry Company, New York. The heating is accomplished without burning or melting the metal and so that an even heat is distributed through the metal at all times.

The heaters are built with one, two, three and if desired with four or five electrodes. The range of heat runs from 1 inch to 8 inches or from 3 inches to 11 inches, with the



Berwick Electric Heater for Bar Stock

possibility of increasing the length by slight changes in the standard heater to 16 inches or 18 inches. Stock $\frac{3}{8}$ inch to $\frac{7}{8}$ inch in diameter may be heated to best advantage on the type machine illustrated, while for larger stock a type 4 machine should be used.

The operation of the heater is along the lines of the Berwick rivet heater. The lower or left hand electrodes are stationary while the upper or right hand electrode is arranged with a vertical adjustment by depression of the foot treadle, which raises the electrode sufficiently to insert or remove the material. Horizontal motion is provided by sliding the electrode clamping device along the shaft provided for the purpose, while as indicated the vertical motion is imparted to the electrode by the depression of the pedal, thus causing the rotation of the shaft, which in turn through cams raises the shaft carrying the electrode.

The material to be heated is inserted between the top and bottom electrodes and due to the double path the time of heating is reduced and the possibility of pitting is not so great. Flexibility of the rear portion of the bottom electrode is provided by the spring shown in the illustration on the rear of the heater, the top face of the electrode being set on an incline so that when the top electrode is dropped in position contact is assured at four points on the material.

Machine for Calking Wood Decks

THE many difficulties generally found in adapting a machine for wood deck calking purposes have been overcome, it is claimed, in an apparatus developed by John McDowall and Sons, Johnstone, near Glasgow, Scotland, known as the "Clyde" deck calking machine. A feature of the machine is an "extended seam" attachment which consists of a hollow guideway so constructed and placed as to form an outward and upward extension of the seam to be calked. Through the tapered opening thus formed by the walls and the guideway, the oakum is compressed by the hammer and enters the seam in a partially

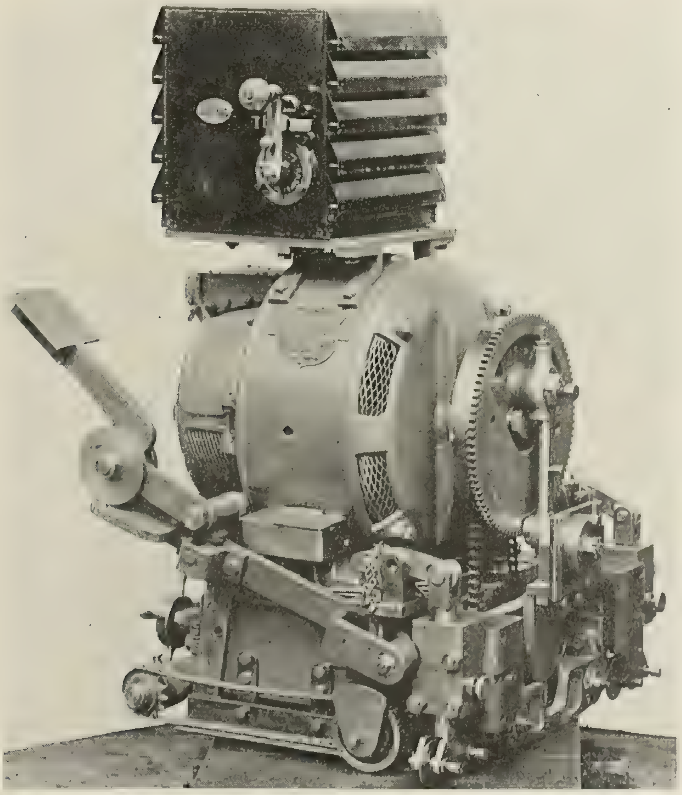


Fig. 1.—Clyde Deck Calking Machine in Position for Traversing

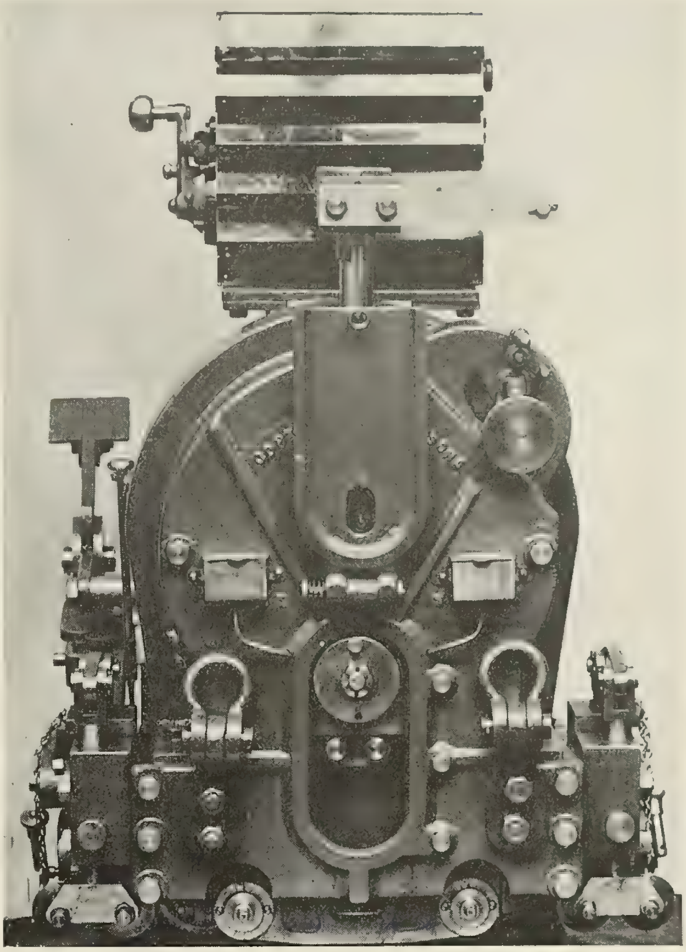

Fig. 2.—Rear View of Calking Machine, Showing Fluted Rollers and Cross Travel Gear

compressed state where it is easily driven into place by the point of the hammer. This hammer is tapered to correspond with the walls of the extended seam and the vertically reciprocating stroke is intended to compress the material into a thread of suitable size to be driven into the crack.

Fluted rollers are fitted to the base of the machine which grip the deck and travel in either direction and which are used for traversing the machine. The calker is kept in alinement with the seam by means of tapered wheels placed in front of and behind the hammer. These wheels adapt the operation to the many irregularities found in even the best laid planking. The oakum thread is wound upon a bobbin which carries about 450 feet, the supply to the tool being automatic.

A special 3 brake horsepower reversing motor, which can be wound to suit either direct or alternating current, furnishes power to the machine. A reversing controller is mounted on the top of the motor as well as the necessary electrical resistance.

A cross-travel gear, operated by means of a foot lever, is also fitted to the machine for the purpose of shifting from seam to seam. When the foot pedal is depressed the machine is lifted on to the wheels placed to travel at right angles to the seam and by the same operation the seam guide wheels are lifted clear of the deck. A handle is then used to wind the machine across to the next seam. When the machine is again in position the oakum is threaded with a special tool and the calker is ready to start.

With the controller thrown in the machine runs without attention until it reaches the end of the seam automatically drawing the oakum as required from the bobbin. The machine will operate in either direction by simply throwing over the controller handle and altering the lead of the oakum.

Passenger Ship Requirements from American, British, French, German, Italian and Spanish Emigration Laws; also United States Lines' Practice

	U. S. Steamboat Inspection Service — Passengers	U. S. Steamboat Inspection Service — Crew	British Board of Trade	French	German	Italian	Spanish	U.S. Lines' Practice. The Practice of the U. S. Lines Is to Provide Comfortable Rooms for Third Class Passengers and Is as Follows:
Baggage space					17.6 cu. ft. per person.			Sufficient baggageroom space.
Bath and washrooms	Sufficient number.	Separate washrooms for deck and engine departments. 1 wash basin for every two men on watch. Sufficient number of baths.	5 basins per 100 3rd cl. passengers; 1 wash trough for every 100 women; 1 wash trough for every 200 men; 3 basins per 100 passengers when basins are fitted in rooms; 1 bath tub per 100 women; 1 bath tub per 100 men (half may be showers)		1 washroom for men and 1 for women; 2 wash basins per 100 passengers; bath and showers required if vessel sails below 30° north latitude; washrooms not required where basins are fitted in rooms.	1 washroom each, men and women, forward; 1 washroom each, men and women, aft; 5 laundry tubs for each washroom; 2 wooden tubs of at least 13-gallon capacity, additional; sufficient bathtubs, showers and basins.		1 wash basin and toilet cabinet in each 2 or 4 berth s.r.; 2 in each 6-berth room; 3 basins in washrooms for every 100 passengers; 1 wash trough for every 100 women; 1 wash trough for every 200 men; 1 bathtub for every 100 women; 1 bathtub for every 200 men; 1 shower for every 200 men.
Berths	Size, 2′x6′; height over deck, 6″; height between berths, 2′ 6″; height under deck, 2′ 6″. Two tiers of berths, only, regardless of deck height. To be separated by partial partitions.	Size, 2′x6′; height over deck, 6″; height bet. berths, 2′ 6″; height under deck, 2′ 6″; two tiers of berths only.	Size, 22″x6′; height over deck, 12″; height between berths, 2′ 6″; height under deck, 2′ 6″; two tiers of berths only. All w.cs. are individual.

S. S. Tjikarang, Built for the Java-China-Japan Line by the Netherland Shipbuilding Company, Leaving Amsterdam for Her Trial Trip

Cargo Steamer Tjikarang Has Limited Passenger Accommodations

WHAT is said to be the largest cargo steamer ever built in Amsterdam, Holland, was completed early this year by the Nederlandsche Scheepsbouw-Maatschappy (Netherland Shipbuilding Company) for the Java-China-Japan Line, Batavia. The *Tjikarang,* as the vessel is named, has a length of 485 feet, a beam of 60 feet, a depth of 40 feet 6 inches and a deadweight capacity of 13,175 tons. Although a cargo steamer, the *Tjikarang* has accommodations for 12 first class passengers, consisting of a dining saloon, smoking room, staterooms for one and two persons, bath rooms, etc. In the 'tween deck space there is room for 1,800 natives.

The vessel has two double masts, 8 derrick posts and also a derrick of 30 tons' capacity. Cargo is handled by means of 20 steam winches. The vessel is electrically lighted, has a steam heating installation and cooled provision holds.

Propulsion is by a triple expansion engine of 5,000 indicated horsepower supplied by Werkspoor of Amsterdam, designed to give the vessel a speed of 12½ knots. The vessel was built to Lloyd's highest class.

First Class Dining Saloon

The New M. A. N. Diesel Engine

Four Cycle Type Now Being Built in Germany —First Units to Be Installed on Hansa Freighter

By Our Special London Correspondent

IT is a remarkable fact that oil engine builders in Germany, which was originally the home of the two cycle Diesel engine, are now for the main part reverting to four cycle machinery. It is believed this is largely due to the failures of the two cycle engines in submarines during the war and the undoubted success of the four cycle design, particularly that built by the M.A.N. This concern has now developed a four cycle marine type for cargo ships, the design being quite different in many respects from other engines of this class. It is standardized as a 1,600 brake horsepower plant and twin screw sets will be installed in many of the new German motorships which are now being constructed in the rebuilding of Germany's mercantile fleet.

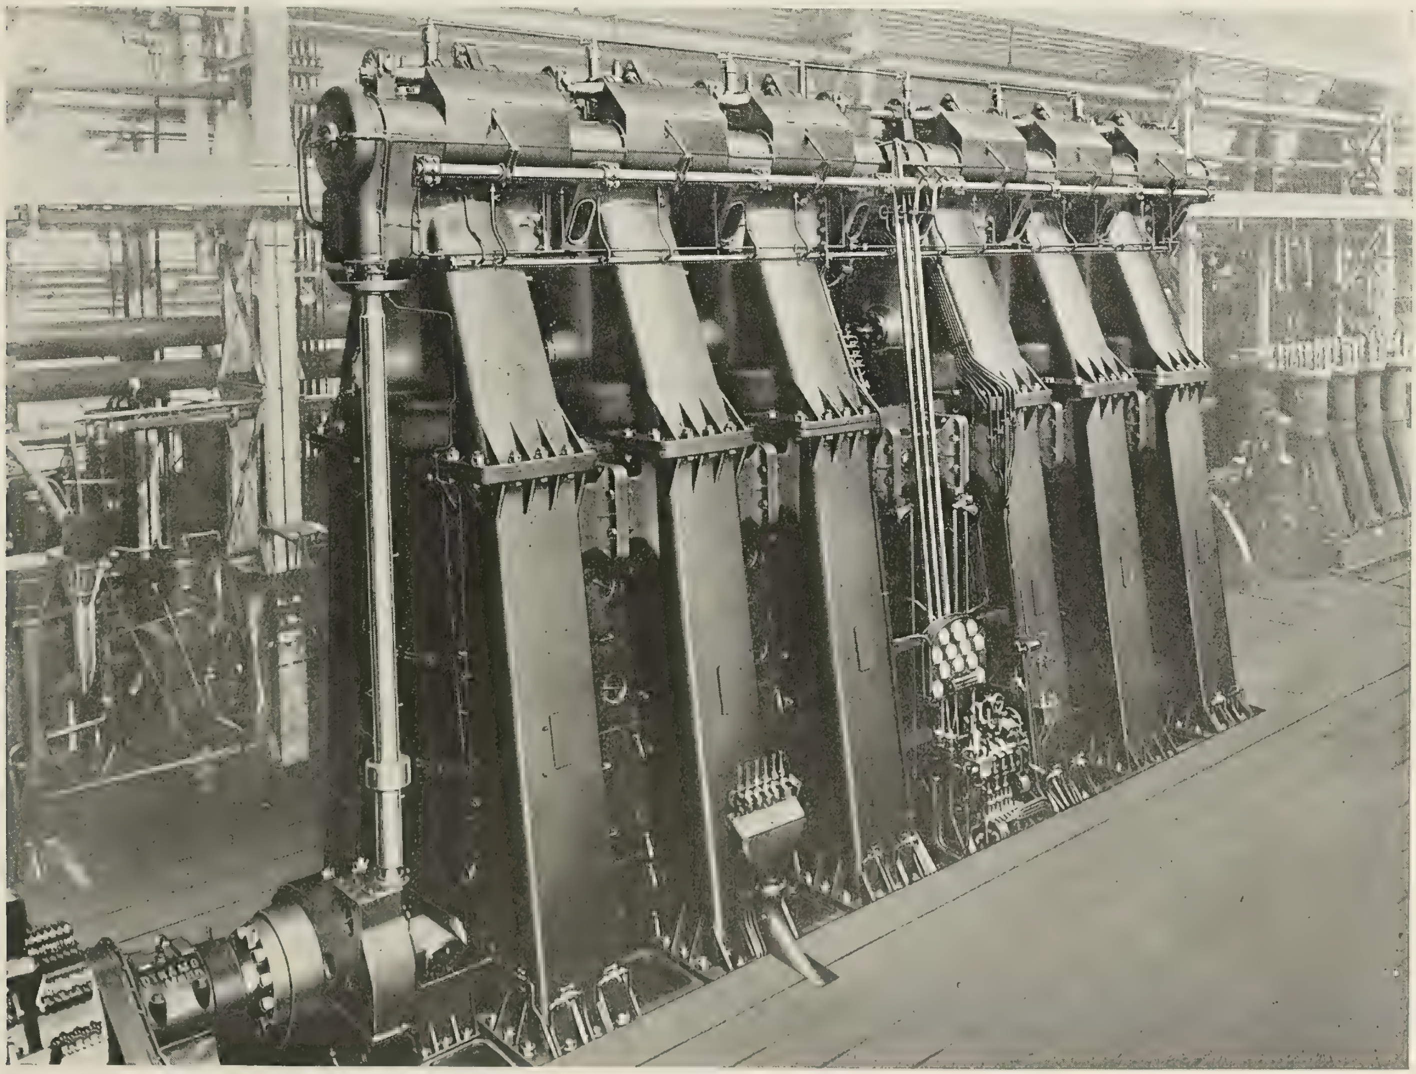
To Run on Boiler Fuel Oil

It has six cylinders 700 millimeters by 1,200 millimeters and runs at 100 revolutions per minute. It is of the air injection type, but instead of driving the air compressors at the end of the engine, as is now common, they are operated from beam levers, two three-stage air compressors being fitted.

The engine is designed to run on boiler fuel oil or, if necessary, on tar oil, as this latter can be obtained at moderate prices in Germany. In order to accomplish this the designers have carried out an idea that has been utilized in Germany with land engines for some years past. A small quantity of lighter oil is allowed to enter the cylinder through the fuel valves just before the piston reaches the top of its stroke and prior to the admission of the main body of the fuel oil. With the rise in pressure consequent upon the ignition of this small quantity of light oil, the temperature is raised sufficiently to allow the heavier fuel to be satisfactorily burned.

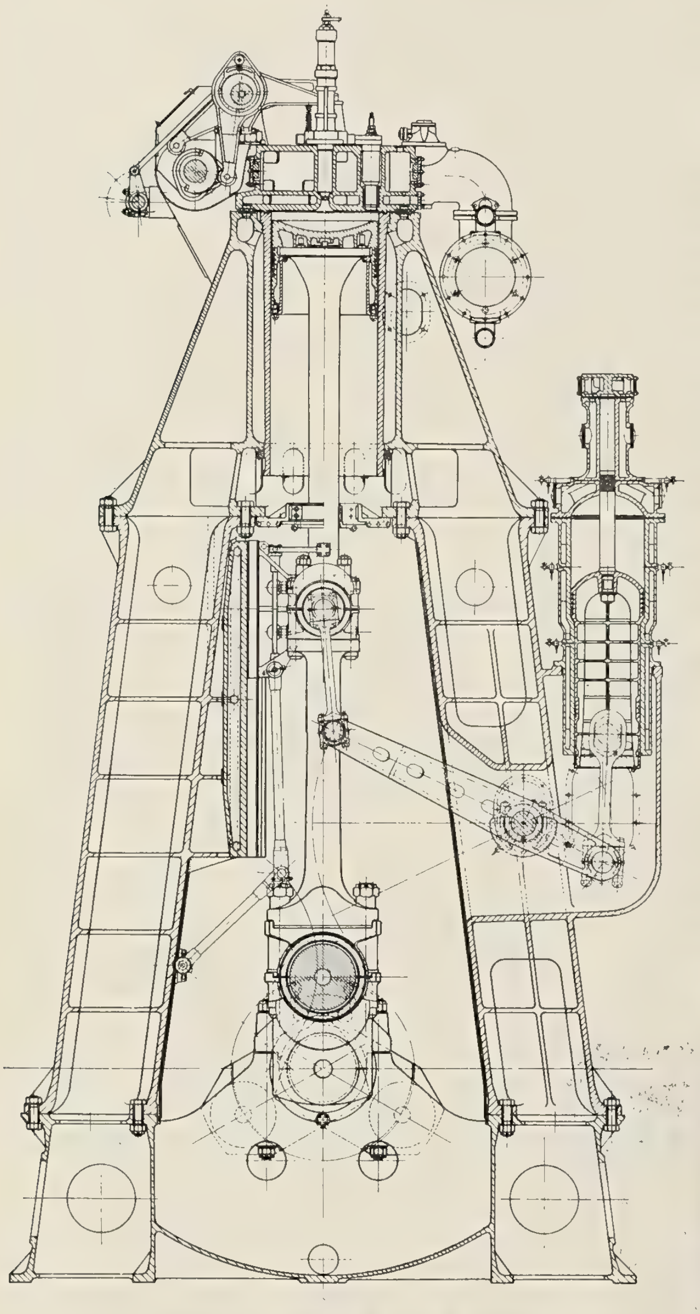
Method of Cooling Cylinder Cover

The builders have evolved a cylinder cover design which appears to be peculiarly efficient. Since cylinder cover cracks, when they occur, naturally develop in the section of the cover next the point of maximum temperature (that is



First of the New Four Cycle M. A. N. Diesels of 1,600 Brake Horsepower Erected at the Builders' Shop

to say, close to the fuel valve), it is of the utmost importance that the cover should be effectively cooled at this section. In order to accomplish this, the builders of the M.A.N. engine have arranged that the speed of the cooling water around the fuel valve shall be greater than in other parts of the cover where the cooling effect is not so essential. They have therefore divided the cylinder cover by a horizontal partition wall and through the lower half the cooling



Section of New M. A. N. Engine

water passes with fairly high velocity. It is allowed to enter the upper section of the cylinder cover through holes cut in the division wall.

Pistons Cooled With Lubricating Oil

It is somewhat surprising to find that the pistons are cooled with lubricating oil instead of water. A flange is forged on the top of the piston rod and this is pressed up against ribs cast within the piston crown. The joint between the crown and the piston flange is maintained through a bush as indicated on the sectional drawing. The ribs on the piston crown, besides giving ample surface for the cooling oil, are so arranged that the oil, flowing up through a hole in the piston rod, passes to the outer section and then through the various divisions formed by the ribs before being discharged from the engine through a tube in the center of the piston rods.

A very rigid form of cylinder cover construction is adopted, each cylinder being supported from two columns, while the columns themselves are joined together with bolted flanges at the top. The cylinder jackets are splayed out at the bottom for attachment on the flanges of the columns, and the bearings carrying the camshafts are supported from the cylinder structure.

Valve Mechanism

The camshaft is driven from the crankshaft through bevel gearing and vertical spindle as seen in one of the illustrations. There are ahead and astern cams for actuating the fuel, starting, exhaust and inlet valves and the camshaft is moved in a longitudinal direction when reversing. The reversing mechanism is operated through the usual oil servo motor, control for which is effected from the engine room floor level.

There are two levers, each controlling three cylinders, and the normal method of starting up is adopted by which six cylinders are placed on starting air, then, three are turned over to fuel oil and finally all six switched over to oil. A hand starting and maneuvering mechanism is provided in the event of failure of the servo motor gear.

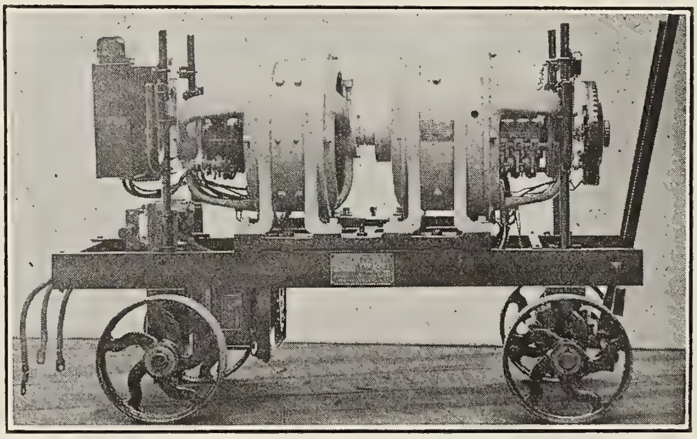
Over the top of the crankcase for each cylinder is a tray which collects the lubricating oil that may fall from the piston, this being delivered through filters and used over again.

The first two engines are to be installed in a motor cargo ship of about 6,500 tons gross, now being built for the Hansa Line.

A Large Capacity Welding Set

A PORTABLE welding outfit of increased capacity is now being built by the U. S. Light & Heat Corporation, Niagara Falls, N. Y. It consists of a motor-generator set and control apparatus mounted on a four-wheel hand truck.

The generator has a continuous capacity of 300 amperes, and for cutting and other work of an intermittent nature will develop 400 amperes. It is designed with inherent regulation and has the same characteristics as the 200-ampere machine made by the same company. The generator is also furnished for belt or gas engine drive.



The 350-Ampere U. S. L. Welding Set

The set is supplied with either a direct or alternating current motor and weighs complete about 1,700 pounds.

United States Navy's Research of Ship Bottom Paint

By N. E. Adamson*

The following article has been prepared from the author's notes on research pertaining to ship bottom paints during the past 12 years, augmented by data drawn from the files at the Norfolk Navy Yard, where most of the Navy's research on this subject has taken place. Because of the great volume of data, a brief description of the tests and the history of the research is given rather than a technical discussion of the subject. For obvious reasons the trade names of proprietary paints and materials are omitted.

TWENTY years ago the Navy used commercial ship bottom paints, purchasing them after the receipt of competitive bids. In order to submit bids for ship bottom paints it was necessary that a manufacturer succeed in getting his paints recognized at the Navy Department and listed as acceptable. The paint used was therefore limited to certain brands and, of these, two or three became more extensively used than the others.

It soon developed that each Navy Yard, where ship bottoms were painted, was forced to maintain stocks of varnish, grease and soap paints of various brands. If a bottom had been painted with a grease paint and required repainting, it was necessary again to use a grease paint or clean off all the old grease paint before applying a spirit varnish paint. Failure to do this was believed to invite unfavorable results from the last applied paint. The docking of ships had to be anticipated sufficiently in advance to allow the yard time to procure the particular brand of paint needed if it was not on hand. It was therefore not unusual to have a supply of anti-corrosive and anti-fouling paints from six different manufacturers in a yard at one time.

It does not appear that the cost of ship bottom paints was considered further than in awarding contracts. The costs of the paints, in general, were approximately $2.10 per gallon for anti-corrosive and $3.25 per gallon for anti-fouling paint. Some paints were purchased by the pound or hundredweight, the costs being approximately $0.20 and $0.30 respectively per pound or $21 and $33 respectively per hundredweight. The saving that the Navy could realize in "first costs" does not seem to have been advanced as a reason for undertaking the manufacture of ship bottom paints, and the fact that a very great saving could be realized only became apparent after the manufacture started, or six years after the first steps were made toward developing formulæ. In the beginning, the manufacture of ship bottom paints by the Navy Department was an effort to standardize—to make it possible to have all the bottoms painted with the same paints so as to require a minimum of paint in stock at Navy Yards and that paint of a constant quality available for any ship's bottom.

*Assistant shop superintendent, United States Navy Yard, Norfolk, Va.

Problems Presented on Starting to Manufacture Ship Bottom Paints

The first official action toward this standardization appears in a Navy Department (Bureau of Construction and Repair) letter dated February 13, 1902 and addressed to the Commandant, Navy Yard, Norfolk, Va. In this letter the bureau requested the commandant to direct the naval constructor to consider the advisability of manufacturing, for the Navy's use, a bottom paint of good quality and to report concerning the cost of establishing a factory for producing the paint in large quantities.

At this time, Rear Admiral C. S. Cotton, U.S.N., was

commandant of the Navy Yard at Norfolk and Captain Robert Stocker, C.C., U.S.N., the naval constructor.

By October 10, 1902, a plant had been established which could produce 208 gallons of ship's bottom paint per day. This amount was considered sufficient to paint all of the Navy vessels every six months, including those at that time being built.

When starting to develop formulæ for bottom paints very little technical information was available. Scientists and technologists had not published any data, so far as could be learned, and practically all data that had been compiled was held by persons engaged in the manufacture of bottom paints. Even at the present time there is very little published on the subject, scientific data which are available being confined largely to a classification of the various species of organisms which make up the fouling on ship's bottoms and to the life history, tendencies, reproduction, etc., of the various species. Dr. A. W. Bray, of the University of Iowa, has recently contributed valuable information on the relative effects of various toxic mediums on various species (his tests being laboratory tests) but it remains for some one to reproduce those mediums on the surface of submerged steel in such a way that the medium will be maintained for six months or longer.

European navies, with two or three exceptions, use commercial brands of paints and, so far as can be learned, in these exceptions varnish paints are used. Such data as I have been able to obtain from these sources are of little technical value as my tests along the lines suggested by the data give negative results in most cases.

Most of the data available from sources outside of the Navy consists largely of records of submersion tests comparing one commercial paint with another commercial paint, very little, if any, information being given about the formulæ. Such tests are usually so limited that the results can be accepted as only indicating and not proving.

With such scant information it was necessary, in starting tests to develop Navy formulæ, to try many combinations and through a process of substitutions, eliminations and alterations finally arrive at formulæ which would produce satisfactory paints.

The problem was to prevent rust and at the same time prevent fouling. Throughout the history of ship bottom paints the thought has been carried that two kinds of paint were necessary, one applied next to the steel to prevent rust, the other applied over the first paint to prevent fouling. (The writer is of the opinion that this is not necessary and that one paint should prevent both rust and fouling. This is shown to be possible by tests of a combination paint described later.)

To prevent rust it is necessary to have either an absolute waterproof film or a film containing that which will prevent rust even though the film is not waterproof. Films that are considered waterproof when applied to surfaces exposed only to air and the action of rain generally deteriorate rapidly under sea water. Granting, however, that an absolute waterproof film could be produced on a ship's bottom, the liability to damage of the film by anchor chains and floating objects is too great to warrant dependence upon waterproofness for preventing corrosion. It was therefore desirable to produce a film which contained that property for preventing corrosion even though water passed through it.

To prevent fouling the film must be toxic or repellent to all forms of fouling which infest the waters traversed by the vessel. Some of this fouling is of the animal kingdom, the most common forms being hydroids, worms and crustacea (barnacles). Some belong to the vegetable kingdom, the most common being algæ or grass.

The anti-fouling film must not contain an ingredient or ingredients which counteract with an ingredient or ingredients in the anti-corrosive film, or vice versa. The paint film must also stand alternate exposure to air and to submerged conditions and both paints must be of such a nature that they may be applied rapidly and will "dry" rapidly.

The First Experimental Paints Produced by the United States Navy

These last named conditions are so desirable that in the beginning of the tests to develop suitable Navy formulæ attention was given solely to spirit varnish paints.

Twenty-one different combinations were used to produce anti-corrosive and anti-fouling paints, the tests of which began in June, 1906. Later thirty additional formulæ were tried. These formulæ are shown in Tables I and II, together with a brief summary of results. The tests were first made on steel plates submerged at the Navy Yard and on the bottoms of yard craft.

The various anti-corrosive paints were used with the various anti-fouling paints at the same time using commercial paints (such as had been extensively used by the Navy) as bases for comparisons. By October, 1907, the tests had progressed sufficiently to indicate clearly the merits of formula number 17 for anti-corrosive paint and formula number 19 for anti-fouling paint as exceeding those of any other formulæ and greatly exceeding the merits of the commercial paints used as bases for comparisons. Here it may be stated that this stage of the development was reached in considering only the first twenty-one formulæ shown in Table I.

The tests of the other thirty formulæ followed. These thirty formulæ are interesting in that some of them show quite a marked departure from a straight spirits varnish paint and contain hard gum varnishes, waxes and various toxines, used both singly or in combinations. While the record of these tests indicates merit in some cases it appears that the paints giving excellent results were not followed up and no departure from formulæ 17 and 19 resulted.

Comparison With Commercial Paints

During the next four years the experiments consisted of painting Navy vessels at various Navy Yards with paints made from formulæ 17 and 19 and with commercial paints to get comparisons on all types of vessels as to relative merit, costs of application, spreading rates, etc. These tests were usually made by quartering the bottoms, applying the commercial paints to diagonally opposite quarters and the Navy paints to the remaining quarters. Typical of these tests were those made on the U. S. S. *Kearsarge, Illinois, New Jersey, Virginia* and *Rhode Island,* the bottoms of which were examined at the Navy Yard, Puget Sound, Washington. The report made on July 8, 1908, was favorable to the Norfolk test paints (numbers 17 and 19). They prevented fouling better than a well-known commercial paint and gave results as to rust and fouling prevention equal to another well-known commercial paint, and were easier to apply. The Navy Yard, Boston, Mass., found that the Norfolk anti-corrosive paint had a slightly higher and the Norfolk anti-fouling an appreciably lower spreading rate than a commercial brand of bottom paints that had previously been used extensively. The Norfolk Yard found the following spreading rates using the same kinds of paints as were used by the Boston Yard:

Norfolk anti-corrosive paint 26 square yards per gallon.
Commercial anti-corrosive paint 26.3 square yards per gallon.
Norfolk anti-fouling paint 24 square yards per gallon.
Commercial anti-fouling paint 24.9 square yards per gallon.

The use of commercial paints on Navy vessels continued throughout this period of experiments. The approved list of brands of commercial paints in 1908 included the products of four manufacturers but in March, 1910, the Norfolk yard had on hand ten brands of anti-corrosive and seven brands of anti-fouling paints in addition to the experimental paints.

(*To be continued*)

Automatic Water Level Adjusting Device for Boilers

It has long been well known by operating engineers that if the water level in a boiler is maintained at its most economical fixed height a great saving in fuel results. Keeping the water level constant by hand regulation is practically impossible, so to obtain the desired result the White Fuel Oil Engineering Corporation, New York, has developed the Todd Thermofeed regulator which, it is claimed, will maintain the water level to within 1/8 inch (watertube boilers 1/4 inch).

The device has but one mechanically actuated valve and depends for its operation on the water level fluctuations. The accompanying sectional views of the regulator and valve illustrate the action of the valve between its two seats and the float action. The valve and seats constitute a single unit which is attached to the top part of a stem reaching from toggles in the float chamber to the top of a valve spindle.

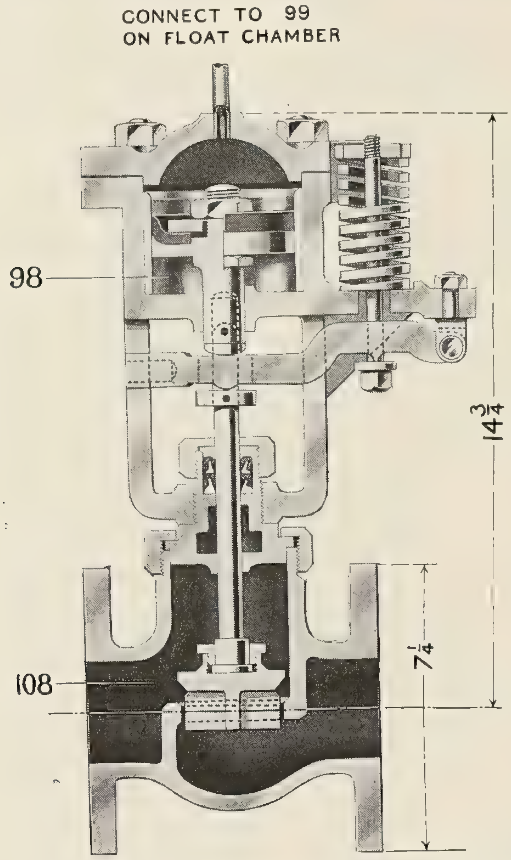

Fig. 1.—Sectional View of Todd Thermofeed Regulating Valve

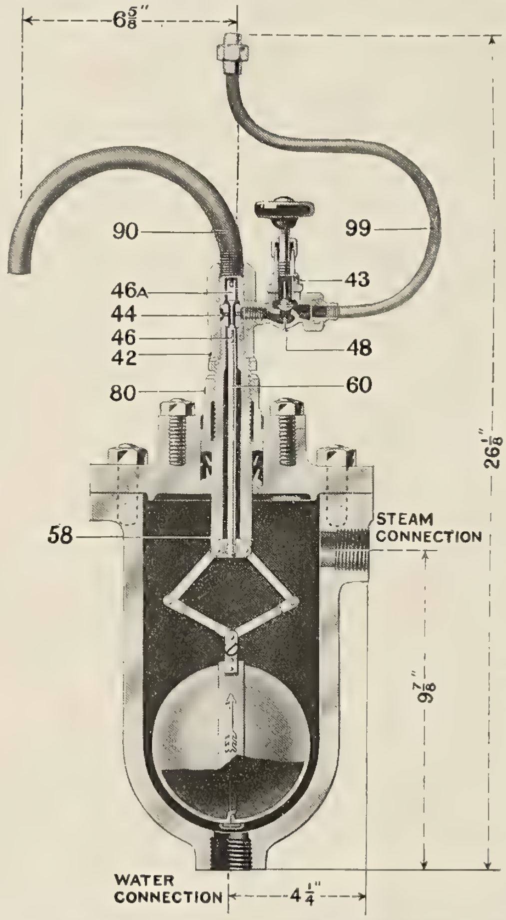

Fig. 2.—Sectional View of the Todd Thermofeed Regulator

The valve and seats together can be removed for examination, cleaning or renewal. The float, which is the only other moving mechanism in the regulator, consists of an electrolytically and hermetically sealed spun copper ball. The float is connected to the regulator feed valve through a 1/4-inch pipe. By shutting off the steam and water valves it is possible to take the whole of the Thermofeed mechanism apart.

Practically the entire function of the regulator is controlled through the three-way valve, marked 43, in Fig. 2. This is a double valve which, when it is on the outer seat in the pipe, allows the cylinder marked 98 in Fig. 1 to be put in communication with the control valve 46 in Fig. 2. When the valve is on the inner seat the cylinder is opened to the atmosphere which puts the Thermofeed out of action. The double seated controlling valve 46 performs the main function of the apparatus and is attached by a rod, 60, to the float through toggle levers so disposed as to reverse the direction of motion. Any movement of the float is diminished in the ratio of 10 to 1 as transmitted through the toggles and the rod 60 to the valve 46. If the water level and the float fall, valve 46 is raised upwards to the lower seat, closing any exit of steam through this valve and simultaneously putting the cylinder 98 in direct communication to the atmosphere by way of ports in 44 and exhaust pipe 90.

If the water level and the float rise, valve 46 is pulled downwards on its upper seat thereby permitting the passage of steam through the lower valve on to the piston in the cylinder 98, in this way gradually depressing the main regulating valve 108 on to its seat.

The entire controlling mechanism in the float chamber is attached to sleeve 58 and can be raised or lowered by the adjusting nut, 80, even when the device is in action. This provides a fine adjustment of the desired permanent water level.

International Chamber of Commerce to Convene in Rome

Several hundred representative American business men will attend the second general meeting of the International Chamber of Commerce to be held in Rome during the week of March 19, 1923, according to an announcement made recently by the American Section of the Chamber. The meeting will bring together leading business men from all over the world for a discussion of world trade problems. Sixteen countries affiliated with the International Chamber will send delegates, while several other countries which have made application for admission to membership in the Chamber will be represented.

Insulating Materials for Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

INSULATING materials of interest in the shipbuilding field are those which insulate against heat, electricity and sound. The first mentioned has two main purposes—to keep useful heat where it will be of greatest value and to keep useful or useless heat from where it would be a detriment. The latter, when not in connection with refrigerating equipment, will be called for convenience of reference Miscellaneous Heat Resisting Insulation. Materials which on account of the high temperatures dealt with are selected more for their refractory properties than for their insulating properties will be classified as Refractory Materials. Electrical insulation is a specialty that is not usually dealt with independently by the shipbuilder and will be only briefly considered.

The principal manufacturers of all of the more important insulating materials have prepared detailed specifications covering their particular fields of usefulness and the best methods of applying them and these specifications will be found to be of great value when dealing with these materials. The manufacturers also give heat transmission and weight data.

Figures of the heat transmission or the heat conductivity of insulating materials, given by manufacturers or others, should be examined to determine which of the two is referred to and how the figures were obtained, because in some cases they are very misleading. Insulating materials offer resistance to the passage of heat through them from one surface to the other and there is a further resistance to the passage of the heat from the surface of the material to the air. The latter is practically uniform with different materials and for a single surface has been found by the Bureau of Standards to amount to 2/10 inch of corkboard or other good insulating material, as a maximum, for interior conditions with quiet air. It is negligible between surfaces of different materials built up in layers. Heat conductivity figures show by inversion the resistance of the material itself and heat transmission figures show both the resistance of the material and the surface resistance.

In the usual shipboard installations the insulating material neither stands alone by itself nor is there a wide air space on each side of it. With flat surfaces there are always external layers of wood or other materials and with pipe coverings there is the pipe on one side and a jacket or other coating on the other. So it is manifest that a comparison of the materials should be upon the basis of their actual internal thermal conductivity and not on the basis of transmission from air on one side to air on the other.

In some cases heat transmission figures are determined by accurate test for a 1-inch thickness of a material and then divided by two to obtain the value of the 2-inch material and so on. The results are necessarily erroneous and unduly favorable to the thicker material.

Tests of insulating materials made by the Bureau of Standards are on the basis of actual internal conductivity. The conductivities of a number of materials tested by them, together with their weights, will be found later on in the article in Table I. Some of these materials are not strictly insulating materials. Tables II and III give transmission or conductivity figures obtained from several sources for the materials principally dealt with in this article and they have some value, if used with discretion and checked up with Table I. The conductivities of some materials increase slowly with increasing temperature while others decrease slowly.

Generally speaking, the less dense a material is the more opposition it offers to the passage of heat. Air would be the best non-conductor of heat, aside from a vacuum, if it were not for the heat conveyed through it by radiation and convection, the former with small temperature differences being by far the principal reason why air spaces are not good insulators. A vacuum bounded by ordinary building materials has been found by the Bureau of Standards to have an insulating value less than ½ inch of corkboard. With air present this will be still lower and for widths greater than one inch will be practically independent of the width of the space, as the radiation factor, which constitutes the greater part of the heat transfer, is independent of the width. The radiation can be cut down to a large extent by running an insulating material through the air space. Convection can be prevented only by dividing the air up into small non-contiguous spaces. Insulating materials derive their efficiency chiefly from the multitude of small entrapped air spaces they contain; the smaller these are, the better.

The principal factors governing the selection of any insulating materials are:

Insulating efficiency.
Durability.
Ease of application.
Non-combustible properties.
Weight.
Cost.

Waterproof qualities are desirable as water adversely affects the efficiency and in most cases the durability.

For insulation of accommodations vermin proof properties are highly desirable.

For high temperature work the material should stand up without fusing or excessive shrinkage.

Refrigerating insulation materials must be odorless and of a nature not to develop odors from decay, mold or other causes.

Structural strength and appearance are factors in some cases.

There are many materials which might be used for insulating purposes on shipboard that are not here dealt with. Some of them will be found listed in Table I. The article, however, deals with the more important of the materials and those in most general use.

Insulation on boilers, pipe fittings and other work which requires to be tested should not be put on until these tests have been made and the work approved by the inspectors concerned.

Refractory Materials

The most used refractory materials are fire brick and fire clay, the latter being required for filling up the joints in the former. Fire brick tile and other materials of the requisite heat resisting properties are on the market and are used to some extent.

Refractory materials are required for lining the steel cas-

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

ings of watertube boilers and similar service. They assist in keeping the furnace at a high temperature and in diffusing the heat.

Fire Brick

In preparing requisitions for fire brick it is usually necessary only to list the sizes required and to specify—

1. That they shall be high grade commercial quality, suitable for coal or oil burning furnaces. Fire brick in an oil burning furnace should be able to stand a heat of 3,200 degrees F. without fusing or cracking.
2. That they shall have a medium, uniform grain and all surfaces shall be reasonably true and free from warpage.
3. That on dimensions of 4 inches or over, they shall not vary more than ¼ inch per linear foot from the specified dimensions. On dimensions under 4 inches they shall not vary more than ⅛ inch per linear foot from the specified dimensions.

The last two items are requirements of the Navy Department, which also requires the trade name or the name of the manufacturer to be molded in each brick and calls for a minimum softening temperature of 3,100 degrees F. and the following chemical properties:

	Percent
Silicon dioxide (approximately)	54
Aluminum oxide (approximately)	41
Basic fluxes as K, Na, Mg, Ca, Fe. determined as oxides (approximately)	5

If the heat and spall resisting properties of the make of fire brick dealt with are not known, and known to be uniform, it is well to request a statement of the guaranteed minimum softening temperature and a chemical analysis of the bricks proposed, showing the percentage of silicon dioxide, aluminum oxide and the basic fluxes, iron, calcium, magnesium, potassium and sodium oxides.

The American Society for Testing Materials has adopted a Standard Specification, C27-20, for determining the properties of fire brick. This specification deals with fire clay bricks with silica content less than 70 percent and silicious clay fire bricks whose silica content is 70 percent or over. The former are required to have a softening point not less than that of a standard cone which softens at about 3,065 degrees F. as determined in a specified manner; and when heated in a suitable furnace to a temperature of 2,552 degrees F. maintained at this temperature for 5 hours, and cooled, they are required to show a contraction of not over 1½ percent of the original length nor an expansion of more than 1 percent. For the silicious clay bricks the softening point is to be not less than that of a standard cone which softens at about 2,975 degrees F., the contraction and expansion being as above; and they must also be subjected to a load test when heated, in accordance with a Standard Test for Refractory Materials, C16-20, with a pressure on the ends of 25 pounds per square inch and a maximum furnace temperature of 2,462 degrees F., after which the brick is to show a contraction of not over 4 percent of the original length and an expansion of not over 1 percent. Bricks with less than 70 percent silica content which soften at a temperature less than that specified above but more than the softening point of a standard cone which softens at about 3,002 degrees F., may still be accepted, if they are put through and pass the tests required, as outlined above, for the bricks with 70 percent silica or over.

Fire Clay

Fire clay should be specified to be high grade and to be dry and ground to such fineness that it will all pass through a No. 20 sieve. Information about sieves will be found in the article on Cement and Concrete for Shipbuilding Purposes.* The Navy Department calls for the same chemical properties as for fire brick and a minimum softening temperature of 3,000 degrees F.

*See Marine Engineering and Shipping Age, May, 1922, page 331.

High Temperature Cements

These take the place of fire clay in bonding fire bricks and such cements should be used rather than fire clay in oil burning furnaces. They can be obtained in various grades to suit different temperature ranges, such as 1,800 to 2,500 degrees, 2,500 to 3,000 degrees, 3,000 to 3,200 degrees, and 3,200 degrees and over. They require a certain temperature to properly flux them and the manufacturer should be informed regarding any set of conditions. The cement should protrude from the joint and be rounded over to protect the corners of the fire bricks.

A suitable high temperature cement thinned down with water so as to form a mixture that can be applied with a brush forms a valuable wash for grouting over the inner surface of furnace linings. Flux mixtures containing silicate of soda, salt, broken glass, etc., should not be used to produce a glaze. Silicate of soda affects the bricks chemically and eventually destroys the lining.

High temperature cement can be mixed up with crushed fire brick to make lining for furnace doors, patches, etc.

Heat Retaining Insulation

Diatomaceous Earth (Kieselguhr)

This is practically pure silica in cellular form, made up of minute shells or skeletons of marine plants known as diatoms which existed ages ago in the waters that then covered the earth. The shells are hollow and contain air broken up into such minute particles that no circulation, with its attendant convection of heat, can take place.

Insulating bricks of which diatomaceous earth is the principal ingredient have about ten times the heat insulating value of fire brick. They are of great value for backing up fire brick in boiler furnaces and similar service. They have too little abrasion resistance for anything but backing. Several proprietary products of this kind are on the market, such as Sil-o-cel bricks and Nonpareil insulating bricks. These bricks are very light weight. The standard size Sil-o-cel brick, 9 inches by 4½ inches by 2½ inches, weighs 1¾ pounds. The standard size Nonpareil brick, 9 inches by 4½ inches by 2½ inches, weighs 1½ pounds. In making the latter bricks the diatomaceous earth is pulverized and mixed with finely ground cork, which is subsequently burned out.

Diatomaceous Earth and Asbestos

Diatomaceous earth mixed with asbestos and compressed forms a suitable covering or lagging for boilers, steam pipes, feed water heaters, evaporators, etc. Thicknesses used are the same as for 85 percent magnesia.

The standard sectional pipe covering is obtainable. Valves and fittings are covered with plastic cement of the same material and thickness.

It is desirable to specify that the insulating qualities shall be equal to those of the best quality 85 percent magnesia covering.

Eighty-five Percent Magnesia

This is the standard covering for the steam and water containing surfaces of boilers and for uptakes, feed water heaters, evaporators, pressure steam pipes and similar services and also for lagging turbines and the cylinders of main engines. It is of course of value for less severe service but in some cases cheaper coverings will answer the purpose. It is very efficient for a high heat material, durable, easily handled and of light weight. Wetting does not damage it and on being dried its insulating value is restored. It is a mixture of hydrated carbonate of magnesia and asbestos fiber, containing at least 85 percent of the former and at least 95 percent of both combined. Specifications for coverings of this material, prepared by the Magnesia Association of America, specify the following thicknesses as representing

good practice for conditions which approximate those on shipboard; and they give charts and tables for determining scientifically correct thicknesses for variations in the determining factors—fuel cost, steam pressure and superheat:

Boilers and uptakes.....................................3 inches total
Donkey boilers ....2 inches total
Pipes—superheated-steam—½ inch to 1½ inches, inclusive......1¾ inches
  2 inches to 3½ inches, inclusive..........................2 1/16 inches
  4 inches and larger....3 inches (double layer), and ½-inch "85% magnesia" plastic cement.
Pipes—high pressure saturated steam, up to 4 inches..............2 inches
  4 inches to 6 inches, inclusive..........................2¼ inches
  7 inches to 10 inches, inclusive..........................2½ inches
Pipes—low pressure steam, exhaust steam, heating system, feed water:
  ½ inch to 1½ inches, inclusive..........................⅞ inch
  2 inches to 3½ inches, inclusive......................1 1/32 inches
  4 inches to 6 inches, inclusive..........................1⅛ inches
  7 inches to 10 inches, inclusive..........................1¼ inches
  12 inches and larger..................................1½ inches
Flanges—superheated steam and high pressure saturated steam......2 inches
  low pressure steam, exhaust steam and heating system......1 inch
Heaters, receivers, separators, tanks, etc—high pressure steam..3 inches total
  low pressure steam..................................2 inches total
  hot water ....1½ inches total
Traps—high pressure ....1½ inches total
  low pressure ....1 inch total

For piping the usual sectional covering in two halves is used, either in a single or double layer, 36-inch sections. When two layers are used they should be applied with the butt and lateral joints broken. The sections are furnished with a so-called canvas jacket pasted on and supplied with bands or wires for fastening; but it is generally desirable to apply rosin sized sheathing paper over the jacket followed by an additional jacket, well sewed on, of 8-ounce canvas as described in the article on Canvas, Bunting and Felt for Shipbuilding Purposes*, the canvas being subsequently painted. Such a waterproof covering is essential on piping to deck machinery and other exposed piping.

Block material on boilers, evaporators, etc., is securely wired in place, covered with galvanized iron wire mesh and then with ¼ to ½ inch of hard finishing asbestos cement troweled to a hard, smooth finish, or with galvanized steel plates. Block material on engine cylinders and similar service is usually held in place and covered by planished iron plates.

For boilers and steam drums No. 14 gage annealed iron wire and 2-inch mesh poultry wire are advisable, while for evaporators and similar service the wire can be No. 18 gage with 1½-inch mesh poultry wire.

The 85 percent magnesia cement covering may also be applied as a cement. This is sometimes desirable on irregular surfaces, but the blocks or sectional coverings are generally preferable.

Asbestos Felt

Asbestos is a mineral fiber and asbestos felt is the pure fiber felted or built up in layers. It is often called fire felt. It can be obtained in rolls from 3/32 to ⅜ inch thick and in sheets from ⅛ inch to 1 inch thick.

It is not as efficient as the 85 percent magnesia covering but is more resistant to vibration. It is decay proof and highly fire resistant. It is frequently used for lining fire doors of boilers and similar service; also for lagging the cylinders of small steam engines, the steam ends of pumps, etc. The flexible sheets are used for a great variety of purposes where there is need for a material that may be folded, bent or wrapped around pipes and heated surfaces.

Sponge Felted Asbestos

This is composed of thin layers of asbestos felt in which are embedded particles of finely ground spongy material, built up in blocks in thicknesses from ½ inch to 4 inches and in sectional pipe covering in thicknesses from ½ inch to 3 inches. Valves and fittings are covered with asbestos cement of the same thickness.

Sponge felted asbestos has the high insulating properties of the 85 percent magnesia covering combined with the resistance to vibration of asbestos felt.

It is desirable to specify that the insulating qualities shall be equal to those of the best quality 85 percent magnesia covering.

Asbestos Paper Products

Asbestos paper is a pulped material made almost entirely of asbestos fiber but having more filler than asbestos felt. It can be obtained in thicknesses from about 1/100 inch to ⅛ inch. The 3/32 and ⅛ inch thicknesses are spoken of as rollboard.

The principal field for asbestos paper as a heat retaining insulation is when it is made up into blocks and pipe covering in various ways. Generally flat sheets and indented or corrugated sheets are cemented together alternately. One make has the sheets separated by narrow strips of the same material. Some of these coverings approach closely in insulating value the 85 percent magnesia covering. A covering of this nature is tougher than the magnesia covering. As the insulating value is largely the result of the air cells formed by the indentations, corrugations, etc., the cheaper grades of this covering are often called air cell covering. In order to avoid the losses due to the heated air traveling along the corrugations, one manufacturer for some years marketed a covering with the corrugations running around the pipe. He found, however, that the trade would not pay the extra cost of the more efficient covering and has brought out a substitute covering with the longitudinal corrugations interrupted at intervals. This can be produced at practically the same cost as with the corrugations forming open channels from end to end. As may be seen from Table II, the air cell covering loses efficiency more rapidly at the high temperature ranges than the other coverings.

In some cases the asbestos paper coverings are more desirable than the 85 percent magnesia covering. An asbestos covering is more durable on vibrating pipes; and the relatively high cost of the latter covering is often not warranted on exhaust steam pipes, heating system pipes, feed water pipes and warm air ducts, where comparatively small temperature differences are met with. The better grades are considerably heavier than the 85 percent magnesia covering but the air cell coverings are of less weight.

Asbestos Blocks

The asbestos fiber matted into blocks and bound together with a fireproof adhesive, or layers of asbestos felt cemented together, forms a covering with good insulating efficiency and great resistance to high temperatures. It may be considered next to 85 percent magnesia for use on uptakes.

Asbestos blocks are suitable for lagging engine cylinders and similar service and in such service are protected by planished iron or other metal covering.

Some high temperature block coverings for special service have refractory materials mixed with the asbestos.

Asbestos Millboard

This is composed of asbestos fiber with a very small percentage of binding or sizing material and can be obtained in sheets from 1/16 to ½ inch thick. There are three standard grades—a hard compact board due to closely matted fiber, a board of medium consistency and a soft board due to loosely matted fiber. The two former are most met with on shipboard.

The Navy Department has prepared detail specifications for this material. Its requirements that are the most valuable for general application are:

1. Boards of uniform thickness, composed of asbestos fiber with a small amount of binding material.
2. Vegetable matter shall not exceed 3 percent by weight of the composition of the millboard and the same shall only be used as sizing.

*See Marine Engineering and Shipping Age, February, 1922, page 131.

3. Millboard shall show no change of texture and no softening when heated indefinitely in a dry heat at 400 degrees F.

4. The loss of weight of millboard after it has been dried to a constant weight at a temperature not exceeding 220 degrees F., shall not exceed 20 percent when a 2-gram sample is cut up and heated to a bright cherry red heat, in an open crucible in a gas muffle for 30 minutes.

5. The maximum acceptable weights for millboard reduced to the basis of 1 square foot area, 1 inch thick, shall be:

Medium millboard .... 6.00 pounds.
Hard millboard .... 6.50 pounds.

Asbestos millboard 1/4 inch to 3/8 inch thick is sometimes used back of fire brick in boiler furnaces. It is of value for lining casing doors and headers and similar service.

Hair Felt

Hair felt insulation is principally used for refrigerating and sound proofing purposes and the nature of the material will be found described under the former heading. It has good insulating value but will not stand high temperatures. It is often used for covering hot water piping.

Wool Felt

Wool felt, which is simply felted sheep's wool, has good insulating value at moderate temperatures. It will not stand high temperatures and after being exposed to dampness it loses its efficiency and eventually decays. With the outside waterproofed and all joints sealed so that water cannot gather in it, such a covering is of value for hot water pipes and similar moderate temperature service.

Wool felt covering for hot water lines has an inner core of asbestos paper.

Mineral Wool

Mineral wool insulation is used principally for refrigeration purposes and the material will be dealt with more fully under that head. It may, however, be well to note that it has been made up into thick sheets and blocks with about one-third of one percent of binder, for use as heat retaining insulation. Such a product is suitable for low pressure work on boilers and piping.

Vegetable Fiber Products

There are many proprietary insulating products of this nature and some of them have been found to fulfill shipboard requirements as heat retaining insulation for spaces where the useful heat has to be conserved, such as in the accommodations of vessels not propelled by steam. Any of them which may be presented for consideration can be readily examined for everything except durability and the character of the ingredients is a good guide to that.

One of these products is a quilt insulation called Linofelt that is made of flax fibers which have been degummed and retted and formed into a batlike cotton batting, and quilted between two sheets of waterproof paper. It can be obtained in 1/4 inch, 1/2 inch, 3/4 inch and 1 inch thicknesses. The 1 inch thickness weighs 0.66 pound per square foot. The thinner products are somewhat heavier in proportion. It is claimed to be mouse and vermin proof.

Another product is Fibrofelt, a semi-rigid material made from hemp fiber and containing a large number of air cells. It can be furnished in large sheets 1/4 inch, 1/2 inch, 3/4 inch and 1 inch thick. The 1 inch thickness weighs 1 1/4 pounds per square foot. In addition to the ordinary grade there is also a waterproof Fibrofelt and a fireproof Fibrofelt. It is claimed to be mouse and vermin proof.

Another product, Flaxlinum, much resembles Fibrofelt but is made from flax fiber which has been rendered rat and vermin proof. It comes in sheets 1/2 inch and 1 inch thick.

Cabot's Quilt is another product suitable for joinerwork heat retaining insulation. It is a felted matting of cured eel-grass stitched between two layers of tough Kraft paper, waterproof paper, or asbestos paper, as desired. It is light in weight, repels mice and vermin and is claimed to be decay proof and uninjured by moisture. The Kraft paper grade is made single-ply about 1/3 inch thick, double-ply about 1/2 inch thick and triple-ply about 3/4 inch thick. The other two grades are of the double-ply thickness.

There are various products made up like wood boards, of materials which have some insulating value, but their properties do not particularly recommend them for this service.

Insulating Paper

Insulating paper might be classed with the other vegetable fiber products but its wide range of service both independently and combined with other insulating materials entitles it to special classification. The best insulating paper is a waterproof paper containing jute, flax and rope stock, saturated and coated with asphalt, which weighs 80 pounds or more per 1,000 square feet, and this weight should be specified as a minimum. It comes in rolls of various widths, the usual width for insulating work being 36 inches.

Refrigerating Insulation

It is especially important with refrigerating insulation that it be efficient and durable in case of becoming wet. It should be sanitary and odorless. Non-combustible properties are not as important as for heat retaining insulation.

A good efficiency requirement for a completed refrigerated compartment installation is that after operating the refrigerating plant for a reasonable time it is to be shut down and the temperature is not to subsequently rise over 1 degree per hour, based on an outside temperature of 90 degrees.

Cork is the principal material for use as refrigerating insulation on shipboard including pipe covering. Balsa wood has been used to some extent for this service. For curved surfaces and surfaces broken up by framing, such as the sides of a vessel, the hold bulkheads and the underside of steel deck over refrigerated holds, mineral wool is considerably used.

Sheet or formed material should be used where conditions permit. It is impossible to make loose insulating materials moisture proof; they are bound to settle leaving unprotected spaces and, if a break occurs in the retaining sheathing, they will run out, with the same result.

All insulation in refrigerated rooms requires an inner sheathing of some kind and where this is wood the wood is preferably spruce on account of its freedom from odor and consequent tainting of the foodstuffs. For the same reason asphalt that is entirely free from odor, and not tar or pitch, should be employed when erecting the insulation of such spaces.

Where a ship is classed, the insulation of refrigerated spaces has to be passed upon by and be acceptable to the classification society concerned.

Corkboard

This is the standard refrigerating insulation for use in partitions, on decks and other flat or nearly flat surfaces. It is also used on curved surfaces in conjunction with a packing of granulated cork or other material. Dried cork in its natural state contains 47 percent of woody fiber and 53 percent of entrapped air.

The most efficient grade of corkboard consists of pure granulated cork compressed in metal molds and baked at a moderate temperature. The baking process brings out the natural gum or rosin in the cork, binding the whole mass firmly together, and no artificial binder is necessary. It can be obtained in sheets 1/4, 5/16, 3/8, 1/2, 5/8, 3/4, 7/8, 1, 1 1/2, 2, 3, 4 and 6 inches thick; the standard size of sheet is 12 by 36 inches. It comes with an odorless asphalt mastic finish about 1/8 inch thick ironed on the surface at the factory. An average weight is about 7/8 pound per square foot for the 1 inch thickness and 1 5/8 pounds for the 2 inch thickness.

One maker of corkboard produces and claims superiority

for a product which contains 4.8 percent by volume and 16⅔ percent by weight of an odorless asphalt binder. The granulated cork is thoroughly dried and then coated with the asphalt at a high temperature. It is then molded into boards under no greater pressure than that necessary to make a close union of the particles. The boards measure 16⅝ inches by 34⅝ inches, or 4 square feet. This material weighs about 1½ pounds per square foot per inch of thickness. Superiority is claimed for this product on the ground that it has a greater weight of cork than other corkboard, that compressing the cork reduces its valuable air content and that burning the cork to break down the elasticity of the cells and make the compression permanent increases its susceptibility to moisture and adversely affects its durability. The greater weight of the product is, however, a detriment for shipboard service. The efficiency has been proved to be less than that of the pure corkboard and the latter stands up satisfactorily against moisture.

Other makes of corkboard with an asphalt binder are obtainable. Cheaper grades of corkboard made of granulated cork mixed with pitch, and probably also containing a certain amount of cork dust and dirt, are also on the market; but they are not desirable for shipboard installations. The pitch is particularly objectionable, as before mentioned.

The Navy Department specifications for corkboard require it to be pure, ground, compressed cork, held together by the natural cork gum as a binder; and they require further—

The cork shall be furnished in sheets 36 inches by 12 inches, in thicknesses of 1 inch, 1½ inches, 2 inches, or 3 inches, as specified. The weight per cubic foot shall be not less than 8 pounds nor more than 12 pounds.

Representative samples of the cork shall be submerged in boiling water at atmospheric pressure for three hours without disintegrating. Immediately upon removal from the boiling water, samples shall be measured for linear expansion, which shall not exceed 2 percent in any direction.

One of the manufacturers of this material recommends for average climatic and building construction conditions on land the following:

Temperature	Thickness
—20 to —5 degrees F.	8 inches.
— 5 to 5 degrees F.	6 inches.
5 to 20 degrees F.	5 inches.
20 to 35 degrees F.	4 inches.
35 to 45 degrees F.	3 inches.
45 degrees and above	2 inches.

This agrees pretty well with the usual shipboard practice.

Cork Pipe Covering

This is one of the most widely used cold pipe coverings. The most efficient quality is made by compressing and then baking pure granulated cork in molds of the proper size and shape to suit the pipes and fittings which are to be covered. The baking brings out the natural gum of the cork which binds the mass firmly together as before stated. As the compressed cork comes from the molds it is coated inside and out with a waterproof mineral rubber finish, ironed on hot. Cork pipe coverings can also be obtained made up with binding material as explained under the head of "corkboard"; and the surfaces are given a waterproof coating.

This covering can be obtained in sectional form to fit any standard pipe from ¼ inch to 8 inches, sections 36 inches long. Special shaped filling pieces are obtainable for use between pipes that are too close together, or back of pipes that are too close to other surfaces, for the standard covering. For pipes larger than 8 inches cork lagging is used. The thicknesses usually required are—

1. Standard brine covering, about 2½ inches thick, for brine and ammonia gas lines, and generally where the refrigerant ranges from 0 to 25 degrees F.
2. Special thick brine covering, about 3½ inches thick, for brine lines, where the temperature of the refrigerant runs below 0 degrees F.
3. Ice water covering, about 1½ inches thick, for use on refrigerated drinking water and liquid ammonia lines, and generally where temperatures of 25 to 45 degrees F. are carried.
4. Cold water covering, for pipes up to and including four inches, about 1 inch thick, for use on cold water piping to prevent sweating. For sizes larger than four inches, use ice water covering.

When calling for this pipe covering as a part of refrigerating apparatus specifications it is usually sufficient to stipulate that the refrigerating supply and return pipes will be lagged with best quality compressed cork of suitable thickness.

The complete covering requires—

1. A putty for filling any spaces that may exist between the covering and the pipes or fittings.
2. A waterproof cement for cementing the joints.
3. A seam filler for smoothing up seams and chipped edges.
4. Copper clad steel wire for holding the covering in place. Copper wire and galvanized wire have not been found satisfactory.
5. Asphaltic paint for coating the outside of the covering to give it a neat and trim appearance.

These materials are obtainable from the manufacturer of the covering.

Cork Lagging

This is of the same character as cork pipe covering, but is denser and more suitable for the insulation of coolers, tanks, filters, etc., than the regular corkboard. The pieces are beveled to the proper radius and have a mineral rubber finish on both the inner and outer surfaces, ironed on at the factory.

In order to guard against the use of the regular corkboard it is well to specify that the material be pure compressed cork and weigh not less than 1¼ pounds per board foot.

Cork lagging calls for the use of the same putty, cement, etc., as listed under the head of cork piping covering except that on brine coolers, tanks, etc., the lagging is usually held in place by iron bands about 1 inch wide, and No. 20 gage, which are drawn up tight by bolts through clips riveted to the ends of the bands.

Usual thicknesses are as follows:

Temperature	Thickness
Below 5 degrees F.	6 inches.
5 to 20 degrees F.	5 inches.
20 to 32 degrees F.	4 inches.
32 to 55 degrees F.	3 inches.
55 to 65 degrees F.	2 inches.
Above 65 degrees F.	1½ inches.

Granulated Cork

Granulated cork comes in several degrees of fineness. The standard grade for insulating purposes will all pass through a ½ inch mesh screen and weighs about 6½ pounds per cubic foot.

Granulated cork is of value for packing in back of corkboard or cork lagging on curved and irregular surfaces. It is used considerably for this purpose in the holds of refrigerated ships as well as when insulating brine coolers, dished heads of tanks, etc. It does not become waterlogged like most forms of loose insulating materials, but possesses their disadvantages in other respects.

Balsa Wood

The nature of this wood has been dealt with in the article on "Timbers and Lumber for Shipbuilding Purposes"* and its value as an insulating material has been there referred to. Its use for such purposes meets with classification society approval. It is a substitute for corkboard in the services mentioned for that material. It is also used in the construction of portable refrigerators. It is too soft to serve as a surface material but has sufficient strength to carry a limited load.

Balsa wood has to be protected from destruction by mois-

*See Marine Engineering and Shipping Age, October, 1921, page 771.

ture. This is accomplished by first steaming the planks in kilns and subjecting them to a subsequent process of slow evaporation until the moisture content is below 10 percent. In this condition the wood is transferred to cylinders where under the required temperature and pressure conditions it is encysted by a proprietary process. This process carries a waterproofing compound through the wood to varying depths, according to the extent of the treatment, coating the ducts and cell walls and preventing thereby access of moisture to the wood structure and destroying the capillarity of the ducts. The owners of this process recommend that the surface be given an additional bitumen waterproof coating when the wood is to be used for refrigerating insulation.

The above mentioned encysting process somewhat reduces the insulating value of the wood and adds to its weight. The following data regarding this were obtained by the Bureau of Standards as the result of a series of tests with a temperature difference of about 35 degrees F. at a mean temperature of about 85 degrees F. The first column shows the conductivity in British thermal units per 24 hours, per square foot of surface, per degree difference in temperature, per inch of thickness. The weight is in pounds per cubic foot.

	Conductivity	Weight
Light wood, untreated	8.3	7.4
Light wood, light treatment	7.8	8.8
Light wood, light treatment, shellaced	8.3	8.4
Light wood, bitumen coated	7.9	9.6
Light wood, medium treatment	8.6	11.8
Medium wood, untreated	9.2	8.9
Medium wood, light treatment	9.2	9.6
Medium wood, medium treatment	10.7	14.7
Medium wood, heavy treatment	12.9	16.8
Medium wood, very heavy treatment	21.6	41.6
Medium heavy wood, untreated	14.0	20.5
Medium heavy wood, light treatment	13.8	20.8

Although a considerable number of shipboard installations of Balsa wood as a refrigerating insulation have been made in recent years, the writer does not feel that they are sufficient in number or age to fully determine the durability of this material, even with thorough encysting.

As stated in the earlier paper, the cost of Balsa wood insulation may in some cases be expected to compare favorably with corkboard insulation; the weight is as above given and the combustible properties of the encysted wood are not much worse than the usual run of refrigerating insulating materials, with the exception of mineral wool.

(To be continued)

Self-Operating Water Circulator for Scotch Boilers

A NEW type of water circulator, known as the "Compulsoree," designed to pick up cold water from the bottom of the boiler and discharge it just above the working water level thus creating a positive circulation has been developed by N. E. McClelland and Company, Ltd., 2-4 Stone street, New York.

The circulator consists of a steel cylinder to which are affixed by electrical welding two cast steel heads, one at each end, the heads being constructed with lugs by means of which the instrument is secured in the boiler, and having openings to accommodate leads of piping. The assembled instrument is located in the Scotch type of boiler as shown in the diagram.

The "Compulsoree" operates on the principle of an air or steam lock, air being the actuating gas until as the water in the boiler gets hotter air is replaced by vapor.

During the process of filling the boiler, water rises in the suction leg of the instrument until a level is reached where the bend at the top of this leg is entirely submerged. At this moment, the water in the suction leg overflows into the enlarged chamber of the "Compulsoree" and falls by gravity to the bottom of the chamber. As the water drops into the chamber, it displaces an equivalent amount of air, but owing to the increased size of the chamber over the suction pipe it is impossible for a sufficient amount of water to fall into the chamber necessary to force out all the air. Therefore, a moment is very quickly reached where atmospheric pressure in the discharge leg, the end of which is at all times above water, plus the weight of water which has fallen into the chamber, will compress the air remaining in the chamber sufficient to prevent a further rise in the suction leg above

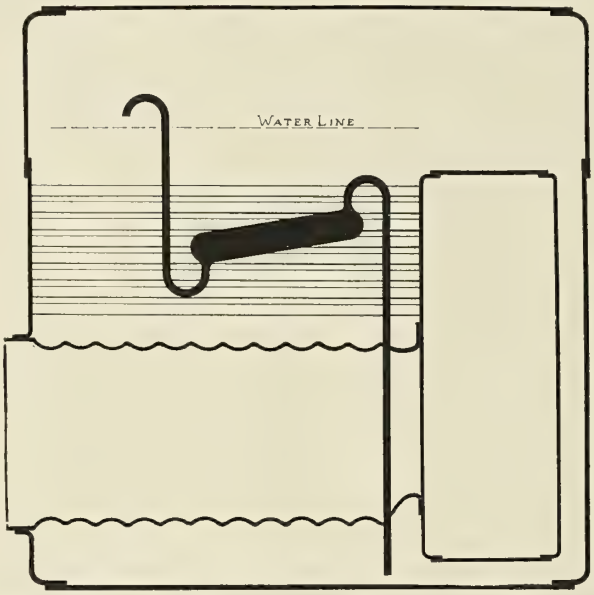

Diagram Showing Arrangement of "Compulsoree" Circulator Installed in Scotch Boiler

the level where it is held in check by the pressure as described.

An air lock is now formed between the column of water in the suction leg and the water which has accumulated in the chamber of the instrument.

When the process of filling the boiler to the required level is complete and the fires lighted, hot gases passing through the fire tubes impart heat to the "Compulsoree" chamber thereby causing the air imprisoned in the chamber to expand and force the water lying therein out through the discharge end along the line of least resistance. The chamber of the "Compulsoree" being now empty, water again rises in the suction leg and overflows into the chamber causing the whole process described above to be repeated. Following the first discharge of water the cycle of operation becomes continuous, cold water being picked up from the bottom of the boiler and discharged into the warmer water on top at the rate, it is claimed, of one gallon every four seconds.

The circulation created by the "Compulsoree" within the boiler is entirely independent of any outside influence as there are no connections on the outside of the boiler whatever. The instrument is constructed of high quality material with no valves or working parts to get out of order. It has been adopted by many of the leading steamship owners and railroad companies throughout the world.

Trial of Diesel Engined Yacht Cynthia

ON July 20 the yacht *Cynthia,* which was designed by Cox and Stevens, naval architects, New York, and built by the Tebo Yacht Basin Company of the Todd Shipyards Corporation, New York, was given an official trial. The *Cynthia* is 129 feet overall, 122 feet 3 inches on the load waterline, 23 feet beam and 6 feet 6 inches draft.

She is a twin screw vessel engined with two Winton 250 horsepower 4 cycle, 6 cylinder full Diesels which propel her at a speed of 12 knots.

The fuel storage capacity of the vessel is 30 tons which, at a guaranteed consumption of not over 0.4 pound per horsepower hour, is sufficient to carry her for a long time without refueling. Electricity is provided by one 5-kilowatt and one 7-kilowatt gasoline generating sets and also by a 100-cell Edison storage battery.

The engines gave a very satisfactory performance on the trial, running smoothly at various speeds. The accommodations for the owner and his guests are commodious and handsomely finished and the general appearance on deck gives one the impression of greater space than would be expected to be available on a yacht of this size.

Diesel Engined Lighter Shows Remarkable Economy in Operation as Compared with Steam Lighter

CONCRETE evidence of the savings possible with a Diesel engine driven harbor vessel is shown by the engine room log of the new motor lighter *Worthington,* described in our April issue. The boat has been in operation for several months so that it is now possible to judge the fuel economy of this method of propulsion. The value of these results is greatly enhanced by comparative figures taken from the records of the steam engined lighter *Daniel Webster,* previously operated by the Worthington Corporation.

An analysis of the Diesel lighter's movements and fuel consumption was made covering the month of April, 1922, with the following result:

300 horsepower main engine in operation..	75 hours 31 minutes
50 horsepower auxiliary engine in operation	105 hours 50 minutes
7 horsepower lighting set in operation....	35 hours 30 minutes
Total fuel used	1,616 gallons
Total cost of fuel used at 4 cents per gallon	$64.64

On a mileage basis the fuel cost during this month averaged 10 cents per mile. Small vessel owners will appreciate the significance of this figure.

While the preceding data are interesting from the standpoint of the fuel operating cost that has been realized in actual operation, the interest in these figures is heightened when the Diesel lighter is compared with the steam driven vessel. The following table gives comparative figures for the new Diesel lighter and the old steam lighter showing the comparative sizes, power and fuel cost:

	Steam Lighter	Diesel Lighter
Length, feet	131	133
Beam, feet	28	34
Hold, depth, feet	11	11¾
Gross tonnage	216	333
Derrick capacity in tons	12	20
Horsepower, main engine	175	300
Hours under way per month....	59 (average)	75½ (Apr. 1922)
One month's fuel cost in dollars (coal at $8 per ton)........	$410 (average)	$64.64

From this table it will be noted that while the Diesel lighter is larger both in point of tonnage and propelling power and while it was under way 75½ hours during one month, and the steam lighter averaged only 59 hours per month, still the Diesel lighter fuel cost was only slightly more than one-seventh as much as for the steam vessel. In other words, the Diesel lighter operated many more hours with an engine developing greater horsepower and used only a little over one-seventh as many dollars worth of fuel as the steam lighter. If the Diesel lighter figures are corrected to a 59 hour basis to conform to the average figures for the steam vessel, we then have $410 total cost in one case for 59 hours operation, as against $50.74 oil cost on the other. When the two figures of $410 and $50.74 per month are plotted, as in Fig. 1, the whole story of fuel cost for a year or any part of a year is shown at a glance. There are of course many savings supplementing the fuel economy which are effected by the Diesel drive that have been presented in other discussions on the subject, but in these directions, too, the Worthington lighter gives us concrete and definite facts.

The Diesel lighter log shows that she fueled on March 17 and on May 18, two months later, but still had 500 gallons of fuel oil aboard. Two months constant operation certainly means time and money saved and to this must be added the facts that the Diesel lighter spent no time out at the ash scow and no time at the water plug.

Any figures worked up on the basis of the foregoing data to show fuel consumption per horsepower per hour are apt

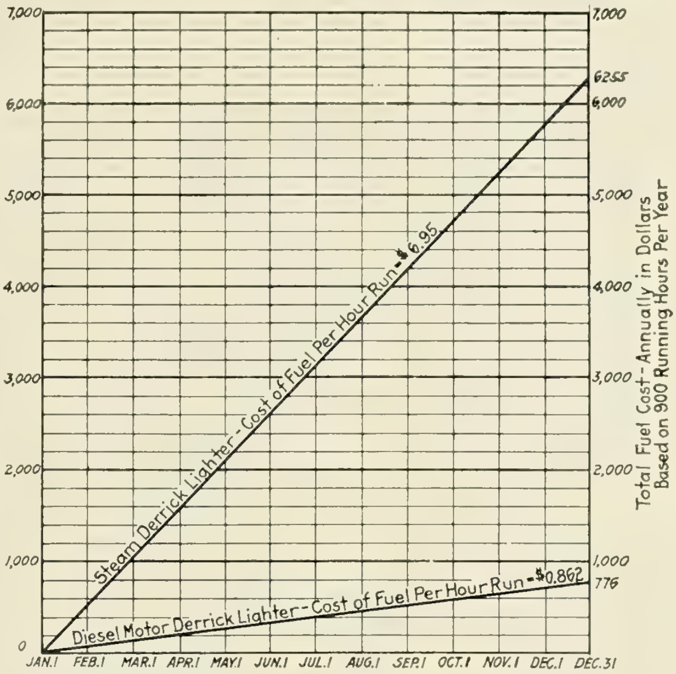

Fig. 1

to be misleading because of the conditions under which any lighter must operate. A lighter must go through too many maneuvers in plying about the harbor to make a guess as to the actual load on the engines at all reliable. For instance, the Worthington lighter's log shows that the main engine was started ahead or astern anywhere from 12 to 50 times at every pier landing during the month of April. It might be mentioned in passing that this is indeed a tribute to the flexibility of the Diesel engine and certifies to its reliability in maneuvering.

The lighter has made only one long run, but this furnishes rather definite information for this kind of service. First the lighter spent 4½ hours loading cargo in Bayonne, N. J., thence she ran to pier 13 North River (a 1½ hour run) and from there in a quartering 70-mile gale to New Haven, Conn. (an 8 hour run). The trip was made with 160 tons of cargo aboard, and the entire operation from Bayonne to New Haven consumed only 192 gallons of fuel. At 4 cents per gallon the cost was $7.68 for fuel burned during the entire trip. At another time 65 tons of pumps were unloaded and dropped into the hold of the steamer with 64 cents worth of fuel.

SETTLEMENT WITH BRITISH MINISTRY.—Chairman Lasker of the Shipping Board has announced that negotiations with the British Ministry of Shipping for settlement of claims, arising out of transactions during and after the war, have been concluded by the payment by the British Ministry of Shipping to the Shipping Board of $12,000,000.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Cause of Break at Point of Admission on High Pressure Indicator Card

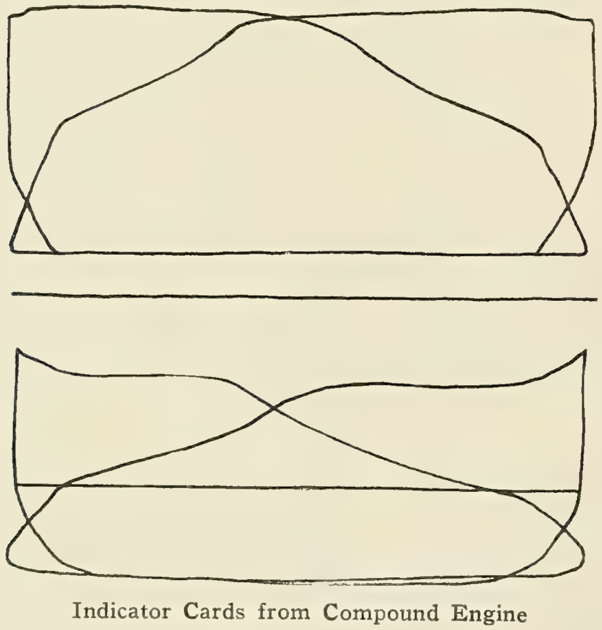
Q. (1164).—I am sending two indicator diagrams taken from an 18-inch by 38-inch by 26-inch compound condensing marine engine operating at 145 pounds steam pressure and 25-inch vacuum, 91 revolutions per minute at ⅝ cut-off. The high pressure card was taken with a 70-pound spring. What I am particularly interested in is to determine the cause of the break at the point of admission on the high pressure card.

At the time this card was taken, the boat was pulling a tow, and on the previous day's run, when the boat was running light and the engine turning 103 revolutions per minute, the card at the point in question was perfect.

My explanation is that there is lost motion in the valve gear and, under the load and slower speed, the valve overreached, causing lap and late admission. Another explanation is that these breaks were caused by condensation in the cylinder, to which I could not agree.

I will be pleased to have any information you or your correspondents could give to clear up this point.

A. (1164).—The high pressure card accompanying this question shows a break at the point of admission. This is caused by too late setting of the eccentric, resulting, as



Indicator Cards from Compound Engine

the valve starts to open, in wire drawing. The eccentric should be set ahead of its present position.

The reason this break does not appear when running light is in all probability due to the use of an indicator spring too light for the duty required. The speeding up of the engine from 91 revolutions per minute, while towing, to 103 revolutions per minute, while running light, undoubtedly gave enough added momentum to the pencil motion or the indicator piston spring to carry the pencil above the true admission condition thus tracing a perfect card at the point in question.

It is believed that, if cards be taken with a 100-pound piston spring, the break will show when running light as well as when towing.

Problem of the Hull and Its Screw Propeller

Q. (1165).—Referring to the paper on the above subject published last year in MARINE ENGINEERING AND SHIPPING AGE:

Type 2 vessels with basic slips of first order, whose value v/V and e.h.p./E.H.P. corrected for K, plots below basic S curves on Fig. 8 will have their Zs value taken from curve 2, Fig. 7, instead of curve 1. Should K be greater than unity in the case just mentioned, use 1.26 K in formula for I.H.P.d. (Pages 454 and first column, page 456, June, 1921, issue).

If the point referred to above plots on curve S, then I.H.P.d (lower part of first column, page 456, June, 1921, issue) equals I.H.P./10^{zp} x 1.26K, but if it plots below the curve S, then Log I.H.P.d equals Log I.H.P. plus 2 Log K (using 1.26 K for K)—2Zp plus Z_1 where Z_1 equals Zp value for e.h.p./E.H.P. corresponding to point on S curve (Fig. 8) where v/V intersects S curve. This is the formula given on page 456, June, 1921, issue (upper part of second column).

Referring to page 454, first column and thirteenth line from bottom; what is meant by the sentence beginning "These two types and type 2 of first order of apparent slips, etc."? There seems to be no formula given anywhere for I.H.P.d when plotted point on Fig. 8 falls below "C" curves.

Referring again to page 456, second column (lower half of column): Formula for I.H.P.d (type 2 vessels, second order of slip) is stated to be Log I.H.P.d equals Log I.H.P. plus Log K—2Zp plus Z_1 (if plotted point falls below upper set of "S" curves, Fig. 8).

In the formula at the top of the same column "2 log K" is used. Are both formulæ correct? There seems to be some discrepancy, for on page 403 of the May, 1921, issue, "2 log K" is used in explaining the reason for excess of actual power over estimated power in case of the fifth vessel, which vessel appears to fall under condition explained on page 456 of June issue, lower part of second column.

(a) What are the lower set of "S" curves (lower three of which are marked "C" and others—S-27 down to S-15), Fig 8 for? I find no formulæ for cases where plotted point falls below them (May, 1921, issue).

(b) Does e.h.p. in formulæ represent horsepower required to tow full size model? (Refer to Admiral Dyson's propeller formulæ.)

(c) Are "I.H.P.d" and "s" for types 1 and 3 vessels always determined by formulæ given in the May, 1921, issue, regardless of position of plotted point on Fig. 8? (Neglecting, of course, condition mentioned on page 553 of the June, 1921, issue.)

(d) Will tow boat propellers turn the same number of revolutions when towing as when running free, assuming tow does not interfere with flow of water either to or from propeller, and assuming steam pressures equal in both cases?

(e) Where can one find reliable tow boat propeller design data?

(f) Referring to Fig. 6, May, 1921, issue, are block coefficients on curve for type 2 hulls same as those on curve for 1 and 3 hulls, if projected on a horizontal line? For example: On curve for 1 and 3 hulls S.B.C. .50 falls on curve A = 30, will the same S.B.C. for type 2 hulls fall on curve A = 23.75 (approximate)?

A. (1165).—Your interpretation as to type 2 vessels with basic slips of the first order is correct.

The sentence referred to on page 454, beginning "These two types, etc." is in error and should read "These two types pass on down to v/V values shown by curves C, Fig. 8, etc." In connection with this sentence it should be stated that the correct location of these "C" curves has been and still is the cause of much study and uncertainty due to the scarcity of data of vessels showing true dispersal of the thrust column. For example, the destroyer now being classed as a type 1 vessel seems to fulfil the requirements of that class, yet due to the fact that it does not show a genuine dispersal of the thrust column nor cavitates at the points expected when referred to the "C" curves, brings a doubt as to whether it is not in reality a type 2 vessel.

When the plotted point falls below the "C" curves of Fig. 8 a "C" curve below those shown may be plotted in the following manner: Choose as a basis some curve such as S = .10. If it is desired to plot say an S = .05 curve, the value on that curve corresponding to any e.h.p./E.H.P. would be [(1-.10)/(1-.05)] × (the value of v/V on the S = .10 curve corresponding to the particular e.h.p./E.H.P. being used.)

The formlua referred to in the second column of page 456 is in error and should read: Log $I.H.P_d = \log I.H.P. + 2 \log K - 2 Z_p + Z_1$.

(a) The lower set of "S" curves, Fig. 8, are to be used with types 1 and 3 vessels and in exactly the same manner as the curves for type 2 vessels.

(b) The e.h.p. used in this article refers to the effective horsepower required to tow the actual vessel.

(c) The same formulæ given in the May issue are used for "$I.H.P_d$" and "S" for types 1 and 3 vessels regardless of position of plotted v/V and e.h.p./E.H.P. points.

(d) Revolutions towing will be less than when running free under conditions cited.

(e) There have been several instances where data were taken while towing United States naval vessels but in no case were the runs made over the measured mile, the speed having been estimated. In order to make an analysis of the data, since no overall effective horsepower was obtained, it would be necessary to add together the effective horsepower of each individual vessel, when available from model tank experiments, under the towing conditions and to this add the estimated power required to overcome the resistance of the idle propellers.

(f) The curve for type 2 vessels was intended for use in cases where information as to a vessel's general dimensions (such as displacement) was incomplete. It was plotted with values of 2 LAB/H and S and bears no known relation to the curve for types 1 and 3 vessels. Since the publication of this article the type 2 curve was abandoned and the types 1 and 3 curve was used for type 2 vessels as well.

NEW BOOKS

Motorship Year Book, 1922. Size, 7½ by 10⅜ inches. Pages, 100. Illustrations, 42. New York, 1922: Miller, Freeman and Company.

Compiled as a standard reference book on oil engines and oil-engined vessels for designers, operators, owners and students, this volume contains a complete detailed register of the motorships of the world, lists of marine Diesel and marine surface ignition engine builders of the world, the American Bureau of Shipping rules for the construction of marine internal combustion engines, Lloyd's revised rules for the construction and survey of Diesel engines and their auxiliaries, the United States Steamboat Inspection Service rules for the licensing of engineers of motor vessels and several articles dealing with matters of interest in the motorship industry.

Of chief value is the data given regarding motorships in existence. The list of vessels has been arranged chronologically according to the year in which the ships were built. As each item is numbered serially and an alphabetical index with the serial numbers accompanies the Register, the data regarding any vessel can be found very quickly. The Register is arranged in tabular form giving the serial number assigned to the vessel, the name of the vessel, its type, the names of the owners and the builders of the hull, the dimensions, tonnage, the number, type and make of engines, the total brake horsepower and the bore, stroke and revolutions of the engine. The Register has been carefully revised since first issued a year ago.

The book opens with a review of American motorship and oil engine construction during 1921. This is followed by a discussion of the use of tar oil fuel for Diesel engines, shaft diameters and ship conversions, exhaust piping and mufflers and forty-nine selected questions and answers for engineers about to take examinations for a marine operator's license for motorships.

LETTERS TO THE EDITOR

Wages Not the Principal Handicap

In the June issue of Marine Engineering and Shipping Age, Captain Eugene E. O'Donnell, manager, marine department, C. H. Sprague and Son, has given his opinions on the question of our merchant marine, and we believe truthfully, as far as he goes, but he has only stated a few of the reasons why we as Americans cannot meet foreign competition.

And, as we believe every American should know the truth, the whole truth and nothing but the truth, we as Americans ask that Captain O'Donnell finish his story, and as marine engineers we must demand in self-defense that the other side of the story be told.

Our reasons for asking Captain O'Donnell to finish are as follows:

First, while his figures as to the pay sheets of the two classes of ships compared with the same class of British ships are no doubt true and correct, we have only to look for a few more figures, also true and correct, and we see where Captain O'Donnell is misleading the public with the truth, but not the whole truth. The figures we ask for are the overhead or the shore expenses of the two companies operating the same class and number of ships, one American and one British; also the Shipping Board overhead for the American ships. If we can believe Admiral Benson's statement to the marine engineers in executive council in Washington, D. C., just before the wage war in May and June, 1921, we could not compete with our British rivals, if the American crews from the captain down worked for their board. Admiral Benson said that the total wages of an American crew was less than seven and one-half (7.5) percent of the total operating expense. Then a little later Senator LaFollette said from the Senate floor that at the very most it would not exceed ten (10) percent.

Now what we want is a comparison of the other ninety (90) percent. All we ask is a fair chance to prove to the world that we as American engineers can and will meet and defeat any kind of foreign competition, provided we are not handicapped with an unreasonable overhead or shore payroll.

Captain O'Donnell takes time to point out several defects in the American maritime laws, or rather what he calls defects. It is evident that he does not intend ever to sail again (if he ever did) or allow any of his boys (if he has any) to sail on anything but a passenger ship. If he did, he would not advise the several changes he has. He also thinks the subsidy bill should not demand more than forty (40) percent of Americans on American ships.

The statement that it will be hard to man our ships with Americans is not true. While it may force some deck and engine room help to become Americans, they are here and eligible and we claim that if this country is not good enough for them to become citizens of our country then the ships of our country are too good for them to sail on.

Portland, Ore. J. R. Snee, Secretary,
Marine Engineers' Beneficial Association No. 41.

Shore Expenses of American Steamship Companies

You have been kind enough to send me an advance copy of Mr. J. R. Snee's letter on "Wages Not the Principal Handicap." This was sent to me in order that I might make reply in view of the fact that he has taken issue with a paper which I presented before the Society of Naval Architects and Marine Engineers, entitled "The Operating Problems of the American Shipowner."

As Mr. Snee's letter deals in generalities and is not specific in character, I can hardly accept it as constructive criticism and while I do not desire to enter into a controversial discussion purely on the basis of generalities I shall, however, in this instance attempt to make a fitting reply.

Mr. Snee assumes to believe that the operating problem of the American shipowner so far as wages are concerned is one that is not entirely confined to the sea-going personnel, but rather emphasizes the fact that the overhead or office expense in the operation of a steamship line is largely responsible for our inability to compete in international trade. In this regard it may be said:

Shore expenses of American and British steamship companies in the operating and traffic offices differ only as salaries and wages on shore are generally different in America and Great Britain. It is doubtless true that American salaries and wages of the shore force are usually higher. It is also true that many current assertions as to the extravagantly high salaries paid American shore officials are grotesquely untrue. As a rule, only one man in an American shipping organization, except one of very great size, has a substantial salary, and he is the executive head who must bear not only executive but heavy financial responsibilities.

Only the Shipping Board can give the "overhead" of its steamers, for which your correspondent asks. As to private companies, I can speak only of my own case. With fifteen persons in our shore office, we are operating 4 steamers of private ownership and 6 steamers for the Shipping Board besides acting for 12 steamship companies calling at this port. I doubt very much whether a given number of British steamers is operated by a smaller force or with an overhead less than our own. The wages of officers and crews afloat have been emphasized in discussions of the merchant marine because these officers and men are so much more numerous and their payrolls are so much greater in the aggregate than those of the relatively small number of people employed ashore.

Wages and costs of subsistence represent together from 12 to 15 percent of the total operating costs of our cargo steamers. Fuel and supplies may be purchased for both American and foreign ships in the world's cheapest markets wherever they happen to be. The wages and subsistence differences are the main differences between our ships and their competitors under the Shipping Board's policy of selling its cargo steamers on the basis of the market prices of the world.

There was no purpose in my paper written for the Society of Naval Architects and Marine Engineers to exaggerate in any point the wage handicap upon American shipowners. We are not paying our good officers any more than they are worth. I did not say nor do I think that the Shipping Board should not demand more than 40 percent of Americans on American ships—I suggested that that was a good practicable point from which to work to the larger requirements of the present shipping bill, which provides that after two or three years at least two-thirds of the unlicensed men in the deck and engine departments must be citizens of the United States. Nor do I ask for any change in the La Follette seamen's law that would make it more difficult for any Americans to go to sea. On the contrary, all we ask in the way of amendments to that law are those that will give American ships and American boys a fairer chance and a more efficient discipline on shipboard. With this I am sure Mr. Snee will as a practical engineer agree.

With reference to the defects in our navigation laws, the recommendations for correcting these defects were made by a competent committee as the result of careful study of the subject, and in further consequence of the suggestions made by practical shipping people including owners, operators, licensed deck and engineer officers and others. These recommendations simply attempt to place us upon a parity so far as our navigation laws are concerned with our principal competitors.

There is no desire on the part of anyone, I am sure, to lessen the requirements for safety of life at sea but this report in effect and in the light of present day experience in reality increases those safeguards in a manner that is comparable with the best modern practice.

The gentleman's statement that it is evident that I do not intend to ever sail again (if I ever did) or allow any of my boys (if I have any) to sail on anything but passenger ships is innuendo and unworthy of an answer. Let me say for the gentleman's benefit, however, that I have sailed for a good many years—from boy to master. My ancestors for several generations were shipbuilders, shipowners or sailors and I should not be in the least surprised to find that my boy in due course will follow in the footsteps of his ancestors and I have no fear for him or any other boy, if the splendid suggestions of the navigation committee are adopted.

Captain Eugene E. O'Donnell,
Manager, Marine Department,
C. H. Sprague & Son.

Boston, Mass.

OBITUARY

Captain Humphrey Jones, a retired sea captain and for seventeen years an inspector of hulls in the United States Steamboat Inspection Service, died recently at his home, 417 East Twenty-fifth street, Brooklyn, N. Y., aged 73.

David Wood, a well known ship draftsman who was admired and respected by all with whom he came in contact, died at the Harbor Hospital, Bath Beach, Brooklyn, on Tuesday, June 27. Mr. Wood was born in Glasgow, Scotland, and served an apprenticeship as a draftsman in the shipyard of Charles Connell and Company. Afterwards he worked at the yards of Henderson Brothers, John Brown and Company on the Clyde and at the Harland and Wolff yard at Belfast.

David Wood

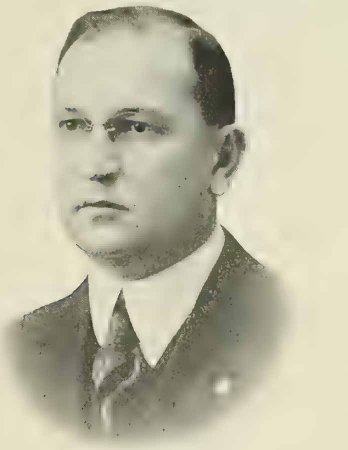
He came to the United States in 1896 and since then had worked at the following places: William Cramp and Son's Ship and Engine Building Company, Harlan and Hollingsworth, Newport News Shipbuilding and Dry Dock Company, Baltimore Dry Docks and Repair Company, Brooklyn Navy Yard, Bureau of Lighthouses, Emergency Fleet Corporation and the Federal Shipbuilding Company.

Mr. Wood was perhaps best known at the Brooklyn Navy Yard where he served 16 years. Recently, however, he had been connected with the Federal Shipbuilding Company and it was while at work at that plant on June 20 that he was taken ill. After receiving temporary treatment at the yard's hospital, he recovered sufficiently to be able to go to his home in Brooklyn where it was hoped that a few days' rest would set him on his feet again. On June 22 he was taken to the Harbor Hospital where he was operated on for appendicitis. After the operation he seemed cheerful and hopeful of being restored to health but unfortunately pneumonia set in from

which in his weakened condition he was unable to rally.

Funeral services were held at the undertaker's chapel on Ashland Place, Brooklyn, which were attended by a large number of his friends and he was laid to rest on the following day with full Masonic rites.

DAVID D. FARIS, appointed on July 1 as manager of the marine department of the Westinghouse Electric & Manufacturing Company, died suddenly in his office at the East Pittsburgh works of the Westinghouse Company on July 10, from apoplexy. Mr. Faris was born in Wheeling, W. Va., and was educated in the public schools and at the Linsly Military Academy in Wheeling, from which he graduated in 1896, going to work almost immediately for the Bellaire Steel Works, Bellaire, Ohio. At the outbreak of the Spanish-American War, he joined the army and went to the Philippines. Upon his discharge in 1899, at the end of the war, he took up a commercial course in the Elliot Commercial School in Wheeling and then came to Pittsburgh to work in the purchasing department of the National Tube Company.



David D. Faris

In 1901 he entered the employ of the National Cash Register Company in Dayton, Ohio, and a few months later became connected with the engineering department of the Pressed Steel Car Company in McKees Rocks, Pittsburgh. In May, 1904, he was employed in the production department of the Westinghouse Machine Company at East Pittsburgh and then was transferred to the sales department, where he remained for five years. He then was assigned to the Atlanta office as sales engineer, and later was engaged in the Chicago office. In 1912 he was given charge of the Detroit and Indianapolis offices of the Westinghouse Company. When the Westinghouse Machine Company was absorbed by the Electric Company in 1915 Mr. Faris returned to East Pittsburgh and was made assistant to the manager of the power department of the company. In 1919 he became assistant manager of the marine department, in which position he remained until his recent promotion.

Mr. Faris was an associate of the American Institute of Electrical Engineers, the Society of Naval Architects and Marine Engineers and the American Society of Naval Engineers.

PERSONAL MENTION

CHARLES C. MOSS, former inspector of repairs for the Munson Steamship Line, is now associated with Gibbs Brothers, Inc., checking up the work on the turbines of the *Leviathan* at the Newport News Shipbuilding and Dry Dock Company's yard, Newport News, Va.

T. PARK HAY is in charge of the United States Shipping Board Emergency Fleet Corporation office recently opened at 827-28 Marquette Building, Chicago, Ill. Mr. Hay was formerly manager of the St. Louis office of the Emergency Fleet Corporation. Harold C. King is his assistant. Besides acting as an intermediary between agents of American ships and exporters and importers, the office will promote cooperation between the railroads and the merchant marine.

CHARLES M. SCHWAB, chairman of the board of the Bethlehem Steel Corporation and of the Bethlehem Shipbuilding Corporation, Ltd., has been elected chairman of the board of directors of the Chicago Pneumatic Tool Company, Chicago, Ill., succeeding John R. McGinley, retired.

CAPTAIN W. A. HINDON has been made port captain of the United States Shipping Board, port of Boston to relieve Captain John J. Coholon, resigned. During the war, Captain Hindon was on the staff of the commandant at the Hampton Roads Naval Base and also served as executive officier on several navy transports.

FRANK E. SCOTT was appointed on July 1 by the United States Shipping Board Emergency Fleet Corporation as general western representative, with headquarters at Chicago, of the following steamship lines: United States Lines, Baltimore Steamship Company, W. A. Blake & Company, Black Diamond Steamship Company, Export Transportation Company. These companies operate Shipping Board tonnage from the North Atlantic to the United Kingdom and Continental European ports, giving frequent and regular service from all important North Atlantic ports to the important ports in the United Kingdom and on the Continent.

W. L. BUNKER, formerly manager of the Egan Refractory Engineering Company, has been appointed superintending engineer of the United States Lines. Mr. Bunker is a Californian and began his engineering career about thirty years ago. Eight years spent in the shops and drawing offices of the Union Iron Works Company of San Francisco gave him a good foundation for practical marine work and this was followed by several years in the transport service, beginning at the time of the Spanish-American war. He then went with the Pacific Mail Company, serving twelve years on passenger ships running to the Orient, going through all the grades of engineering and serving for the last six years as chief engineer of the S. S. *Manchuria*. Mr. Bunker then went with the Great Northern Pacific Steamship Company, where he worked for three years as chief engineer and superintending engineer. His next position was that of chief inspector of the United States Shipping Board in San Francisco, which he left after six months to enroll as a lieutenant in the Navy, where he served for sixteen months, leaving with the rank of lieutenant-commander. He was one of the first reserve engineers to receive this rank and he left the Navy with an excellent war record, having received a letter of recognition from Secretary of the Navy Daniels.

W. L. Bunker

Upon leaving the Navy, Mr. Bunker again joined the United States Shipping Board as chief inspector in charge of construction and repairs in Philadelphia and New York. After a year and a half in this position, he left to join the Lord Dry Dock Corporation, where he remained for eighteen months as general manager. Again, after one year as marine surveyor in New York, Mr. Bunker became manager of the Egan Refractory Engineering Company, the position which he left to take his present position.

Much of Mr. Bunker's marine experience has been with the handling of passenger ships. He is a diligent worker and has earned for himself the enviable reputation of living up to his motto of "A Square Deal for Everyone."

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Business Improvement

A PRONOUNCED upward turn from the low mark of the post-war ebb in the tide of shipyard business is shown by figures compiled by MARINE ENGINEERING AND SHIPPING AGE for the first half of 1922.

From January 1 to July 1 there has been reported ship construction and repair work as under contemplation having a total estimated value of $73,782,517 and contracts placed for similar work during the same time amounting to $28,905,186.

Figures for the first three months of the year showed $34,927,000 reported as work in contemplation and $14,930,206 in actual contracts placed. For the quarter ending July 1 the figures are $38,855,517 and $13,974,980 respectively.

In addition to these figures, there is at present every indication that contracts for at least seven new combination passenger and freight ships, as well as a number of other types of commercial vessels, will be placed this year.

There is also a strong possibility that orders may be placed in this country for either submarine torpedo boats or submarine mine layers for foreign accounts. Tentative bids have already been received or requested from American builders. The award of any one of the several contracts being considered in this connection would involve many millions of dollars.

Reconditioning of Agamemnon and Mount Vernon, Involving Millions, Receiving Serious Consideration

Washington Officials Understood to Be Investigating Probable Cost of Putting Ships in Service—Action on the President Grant May Be Deferred

FROM $3,700,000 to $4,500,000 will be required for reconditioning of the steamships *Agamemnon* and *Mount Vernon*, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE. It is learned that the question of putting these vessels into shape for service is receiving serious consideration in Washington, as it is believed that the operation of these or similar ships will be necessary to provide running mates for the *Leviathan*.

Unofficial estimates of the cost of overhauling the *Agamemnon* and the *Mount Vernon* placed the totals, including general specifications, oil fuel installation, stewards' supplies and ship furnishings at about $2,500,000 for the former and slightly over $2,000,000 for the latter. This reconditioning would provide for 22 knots speed, using oil for fuel.

For reconditioning the same vessels for 18 knots speed, using coal for fuel, the total figures for the *Agamemnon* would be close to $1,900,000 and for the *Mount Vernon* $1,800,000.

It is believed that the reconditioning of the *President Grant*, including general specifications and stewards' supplies and ship furnishings, would cost about $900,000.

It is understood that in the case of the *Mount Vernon* and the *Agamemnon* preliminary estimates were prepared on a basis of operating the ships at a speed of 22 knots, using oil for fuel, with an alternative estimate of service at 18 knots, using coal for fuel.

It is probable that three months will be required for the preparation of plans and specifications on the *Mount Vernon* and *Agamemnon* and the actual work of reconditioning these two vessels as coal burners would require six months' time and, with oil burners, seven months.

The ships have an over all length of 706 feet 6 inches; length between perpendiculars, 680 feet 4 inches; breadth, 72 feet; depth, 44 feet 2 inches and a gross tonnage of 19,503.

As oil burners, passenger accommodations can be provided for about 600 first class, 300 second class and 600 third class passengers, while, as coal burners, accommodations can be provided for over 500 first class, 300 second class and 350 third class passengers.

Steamship Comus To Be Converted Into Oil Burner

THE steamship *Comus*, of the Southern Pacific Steamship Company, went to the plant of the Robins Dry Dock & Repair Company, Brooklyn, N. Y., of the Todd Shipyard Corporation, where she will be converted from a coal to an oil burning ship.

$1,840,000 Job Awarded Newport News Shipyard

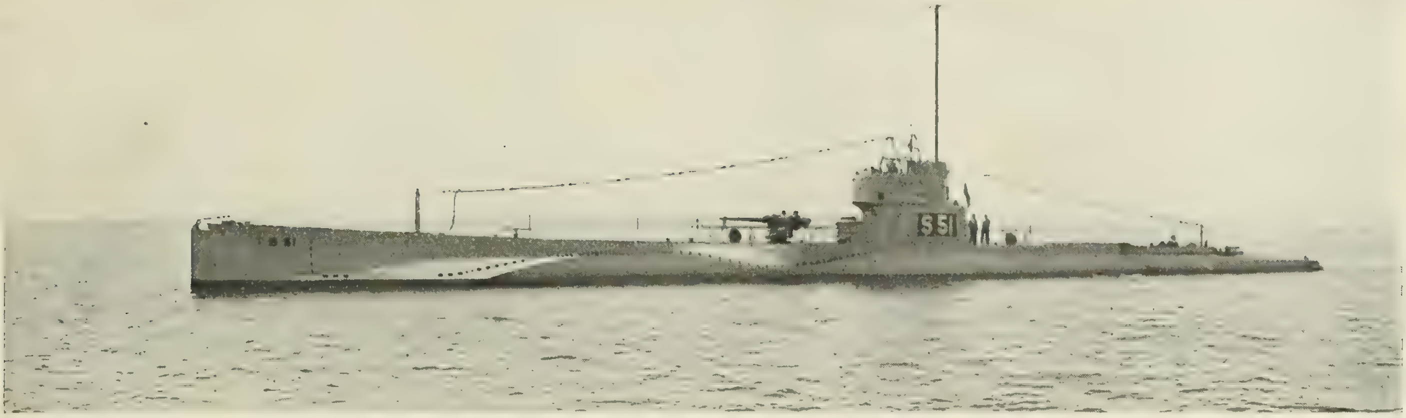
THE Newport News Shipbuilding and Dry Dock Company, Newport News, Va., has been awarded the contract for the construction of two combination passenger steamers for the Ocean Steamship Company, of Savannah, following the opening of tenders at Pier 35, North River, New York, on June 29. There were eleven bids submitted for the work, the Newport News price being $920,000 for each ship.

The vessels will be built of steel, the propelling machinery consisting of inverted, direct acting, triple expansion, surface condensing engines, having cylinders 26, 43 and 72 inches diameter by 48-inch stroke, designed to develop 2,900 indicated horsepower, steam being supplied by four single-ended, cylindrical, return tube boilers. The ships, which are to be similar in type to the company's steamships *City of St. Louis* and *City of Montgomery*, are for delivery in 1923, the first by September 1 and the second by October 1. They will accommodate about 228 passengers each.

Diesel Yacht Contract Awarded Newport News Yard

NEWPORT NEWS, Va. (Special.)—The Newport News Shipbuilding & Dry Dock Company has been awarded a contract for the construction of a seagoing Diesel yacht, 172 feet by 26 feet by 12 feet. The vessel will be propelled by two 350 horsepower Winton Diesel engines.

The yacht was designed by the firm of Cox & Stevens, naval architects, of New York City. It is understood she will be named the *Ohio* and will cost close to $350,000.



S-51, After Completing Successful Trials

Submarine S-51, Last of the Lake Company's Construction Program, Is Officially Delivered

THE submarine *S-51* built by the Lake Torpedo Boat Company, at Bridgeport, Conn., was officially turned over to the United States Government by that company at the Lake shipyard, on Saturday, June 24. With a band playing and flags flying, Lieutenant Commander W. S. Haas, U. S. N., assumed active command of the vessel. Simon Lake, designers and other engineers of the contracting company and a large party of invited guests witnessed the ceremony.

The turning over of the *S-51* to the Navy completes the Lake Company's present building program. The ship is the last word in submarine construction and gave a highly creditable performance when she ran her sea trials recently.

Gahagain Company Takes $491,904 Job for 12 Sea Scows

THE W. H. Gahagain Company, of Brooklyn, New York, has been awarded the contract by the City of New York for the construction of twelve seagoing side dumper scows for use by the Department of Street Cleaning. The company's bid was $40,992 as a unit price with a total figure of $491,904.

The specifications provide for a heavily constructed wooden boat having a length inside of fenders of 134 feet; breadth outside to outside of side planks, 37 feet; depth molded to center top of deck plank to bottom of bottom plank, 14 feet; the boats to be fully equipped.

Conversion of San Lorenzo Awarded To Sun Company

THE Sun Shipbuilding Company, of Chester, Pa., has been awarded the contract to insulate and convert the steamship *San Lorenzo*, of the New York and Porto Rico Steamship Company, into an air-cooled fruit carrier, following the opening of bids at 25 Broadway, New York city, on July 7. The Brunswick Refrigerating Company's machinery will be used and when completed the ship will have about 120,000 cubic feet of space available for cargo. She will be returned to service between New York and San Juan. The successful bid was $138,768, the work to be done in 60 running days.

The steamship company has also purchased a new high-pressure cylinder for the *San Lorenzo* from the Sun Company, which will be installed in the course of the overhauling and during the layup the ship will be classed by the American Bureau of Shipping.

Newport News Yard Gets Middlesex for General Overhauling

THE Newport News Shipbuilding & Dry Dock Company was awarded the contract for overhauling the steamer *Middlesex*, of the Coastwise Transportation Company, following the opening of bids at the office of Frank S. Martin, naval architect and marine engineer, of 25 Broadway, New York City. The contract provides for a long drydocking job including considerable steel work. The bids submitted were as follows:

Newport News Shipbuilding & Dry Dock Co.	$134,986	60 days
Morse Dry Dock & Repair Co.	155,000	57 days
Robins Dry Dock & Repair Co.	157,000	70 days
Alderton Dry Docks	160,000	55 days
Tietjen & Lang	162,354	72 days
James Shewan & Son	165,000	43 days
Bethlehem Shipbuilding Co.	249,800	65 days

Freighter to Be Built by American Yard, Cleveland

THE American Shipbuilding Company, of Cleveland, Ohio, has been awarded a contract by the Pandor Steamship Company, of Cleveland, for the construction of a steel freighter of 12,000 deadweight tons, similar in type to the vessels the shipyard now has under construction for other lake carriers.

The vessel will have a length between perpendiculars of 580 feet, beam 60 feet and depth 32 feet. She will be propelled by a triple expansion reciprocating engine, and cost about $800,000.

Bethlehem Plant Awarded Two Ships For Eastern Lines

THE contract for the construction of two coastwise freighters for the Eastern Steamship Lines, Inc., of Boston, Mass., has been awarded to the Bethlehem Shipbuilding Corporation at a total price of $287,000 each. Bids for the construction of one, two or three of these ships were received on Wednesday, June 14. Construction work will start immediately at the Sparrows Point plant of the Bethlehem Corporation, the first ship to be built in 180 days and the second ship in 200 days.

The ships will be of the hurricane shelter deck type, having an overall length of 233 feet 3 inches, length between perpendiculars 221 feet 6 inches, beam molded 38 feet, load draft 17 feet, 1,400 deadweight tons and developing a speed of 11½ knots. It is understood that the propelling machinery will consist of reciprocating engines purchased from the Shipping Board and built by the Hooven, Owens, Rentschler Company. Steam will be supplied by two, oil burning, single ended, Scotch boilers of the two furnace type, delivering steam at 190 pounds working pressure.

The vessels were designed by Theodore E. Ferris, naval architect of 30 Church Street, New York City.

Robins Yard Gets S.S. President Pierce on Bid of $229,000

THE Robins Dry Dock & Repair Company of the Todd Shipyards Corporation with a price of $229,000 was awarded the contract of reconditioning the steamship *President Pierce*, formerly the *Hawkeye State*, following the opening of bids by the Shipping Board, 45 Broadway, New York, on June 27. The work includes extensive hull and engine repairs.

Self-Unloading Collier Is Contracted For

James Playfair, of Midland, Ontario, has signed a contract with the Midland Contracting Company for the construction of a self-unloading canal sized collier.

Building of Two Steel, Turbo-Electric Ferries Under Way

MARKING the first steel ship contract work undertaken at any Los Angeles yard since the war, the first plans for the keels of two steel double ended ferry boats were laid on June 29, at the plant of the Los Angeles Shipbuilding and Drydock Corporation. The construction contract amounts to $586,000, outside of equipment, and was secured by the local yard in sharp competition with northern shipyards.

The vessels are to be built under the supervision of John B. Matthews, naval architect and engineer, who designed them as the first turbo-electrically driven ferryboats ever laid down in any yard. The propelling machinery is of a similar type as that used in modern warships and is said to provide a saving of 30 percent in horsepower as well as to effect a great economy in fuel and simplicity in operation. The construction work promises to provide employment for several hundred men and this activity taken in connection with the establishment of a modern lumber yard, with sawmills and box factories at the same plant, is expected to re-establish the Los Angeles yards in their old position as among the largest employers of labor in the harbor district.

Bids for Seven Millions in Submarine Mine Layers Requested from Contractors in America

Prices Asked by South American Government for Construction of from Three to Five Vessels in Addition to Undersea Torpedo Boats

A SOUTH AMERICAN government is again in the American market for a number of submarine vessels having an estimated total value of $7,000,000, according to information obtained by Marine Engineering and Shipping Age. Argentine, Brazil and Chile have already received tenders from American builders for the construction of from six to twelve submarine torpedo boats of the latest type, the cost of which would range from five to eighteen million dollars, the latest development being a request for estimates on three, four or five submarine mine layers. It is believed that these latter vessels would involve the expenditure of from $5,000,000 to $7,000,000.

Proposals for vessels of the mine-layer type will probably provide for a submarine about 200 feet in length, driven by two 1,000-horsepower oil engines developing a speed of from 15 to 16 knots.

Each vessel would be equipped complete with auxiliary machinery, including electric motors, storage batteries, mine handling mechanism, pumps, wireless apparatus, etc. Unofficial figures give the approximate displacements of these proposed boats as follows: Net submerged tons, 870; surface displacement, 720; submerged depth, 200 feet.

Contract Placed for Rebuilding of C. & O. Pier at Norfolk, Va.

The J. T. Nuchols Company, of Richmond, Va., has been awarded contract for rebuilding the Chesapeake & Ohio pier and warehouse, burned at Norfolk, Va., several months ago. The amount of the contract has not been made public, but it is believed to be less than the $125,000, which was the amount of the first estimate.

The new pier and warehouses will be fireproof, constructed of reinforced concrete and steel. It will be 450 by 52 feet, approximately, and will more than compensate for the space lost

United States Only Country to Show Increase in Shipbuilding During the Past Three Months

Figures of Lloyd's Register of Shipping Credit United States With Gain from April 1 to July 1—World Shipbuilding Below Pre-War Level

WORLD shipbuilding today is actually below the pre-war level, says a statement just issued by Lloyd's Register of Shipping. The decrease in production has been steady since the fall of 1919, and the volume of new orders continues to be far below the completion of orders in hand.

While the returns for the quarter ended July 1 show that the aggregate of contracts in hand is nearly 800,000 gross tons more than the total at July 1, 1914, so many suspensions of work have been directed by those who placed the orders that the actual volume of construction actively under way is slightly below the pre-war figure.

Although there has been a sharp shrinkage in the gross aggregate of tonnage in hand during the past three months, Lloyd's Register points out, the total for the shipyards of the United States shows a small gain. On April 1, the American aggregate was lower than before the war, but on July 1 it was slightly above the pre-war figure. This country, however, was practically the only one in the world to show a gain during the past quarter.

The gross aggregate of tonnage on July 1, as compared with the previous quarter, was as follows (in gross tons):

	July 1	*April* 1
United States	150,623	136,266
United Kingdom	1,919,504	2,235,998
Other countries	1,165,303	1,307,358
World total	3,235,430	3,679,622

Stoppages ordered on this work fell more heavily on British shipyards than on those of all the other maritime nations combined, says Lloyd's Register, the result being that, while the actual British total is nearly 300,000 tons below the pre-war figure, the aggregate of the other shipbuilding countries is about 250,000 tons higher than in 1914. The following shows the result of the last quarter's suspensions, in gross tons:

	Britain	*Others*
Work contracted	1,919,504	1,315,926
Less suspensions	481,000	290,000
Actual work	1,438,504	1,025,926

The actual construction under way at present, as compared with that just before the war, shows how British shipyards have been affected:

	July 1,1914	*July* 1, 1922
United Kingdom	1,722,000	1,438,504
United States	148,000	150,623
Other countries	626,000	875,303
World total	2,496,000	2,464,430

The world construction now actually under way shows a decline of nearly 5,600,000 gross tons from the peak, which was attained in September, 1919, when 8,048,000 tons were being built, Lloyd's Register states. This country's present total of 150,000 tons, compared with the high level of 4,186,000 tons reached in the first quarter of 1919, shows a decrease of more than 95 per cent.

Bethlehem Begins Construction of Two 20,000-Ton Ships

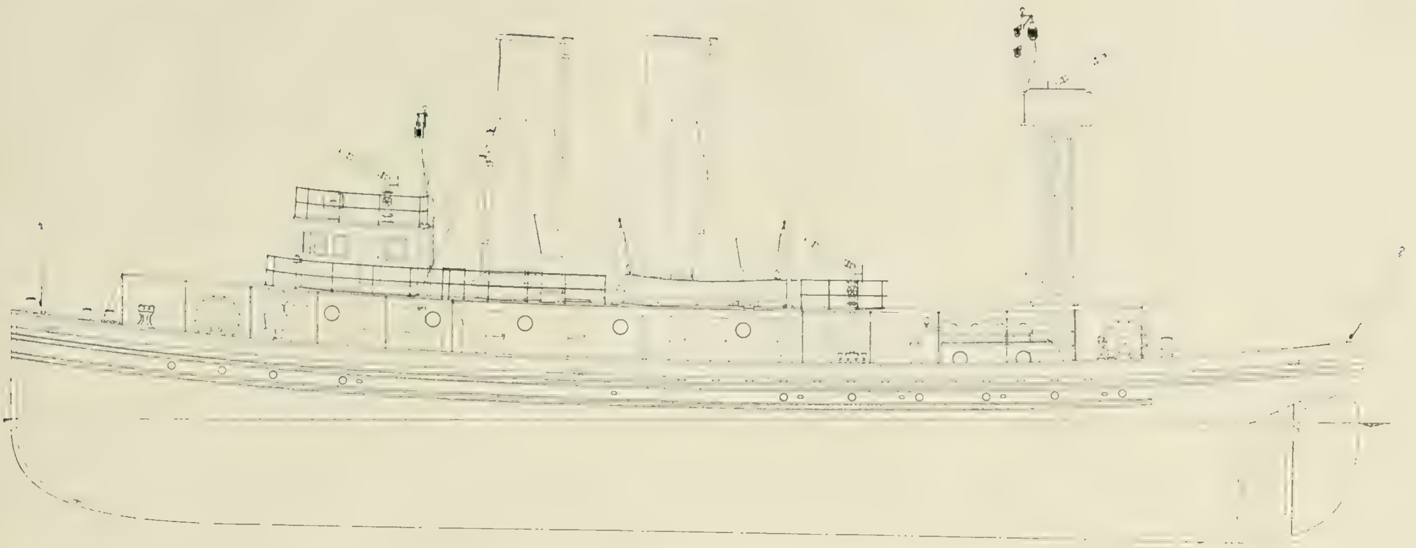
THE Bethlehem Shipbuilding Corporation has begun the construction of two 20,000-ton cargo ships at their Union plant, San Francisco, California. These ships are to be combination ore and coal carriers similar to the ore and oil carriers already built by that company.

The vessels will be named the *Chilore* and *Lebore*. They will each have an over all length of 571 feet 6 inches, length between perpendiculars 550 feet 1 inch, beam molded 72 feet. The propelling machinery will consist of two Bethlehem-Curtis type turbines developing a maximum of 5,000 horsepower. Steam will be supplied by three single-ended Scotch boilers burning oil for fuel and developing a working pressure of 220 pounds. The cargo space of each ship will have a total capacity of 911,856 cubic feet.

Virginian Railway Will Build Three Million Dollar Pier

ACCORDING to announcement by C. H. Hix, Vice-President of the Virginian Railway, the railway will build a new coal pier at Sewall's Point terminals, more than doubling the capacity of the plant to dump coal. The expenditure involved will be about $3,000,000. Bids will probably be asked in the near future as plans are now being prepared. Mr. Hix said that he hoped to have the preliminary work on the pier started in two months and that it should be completed in two years.

Construction of the new pier will add about one-fourth to the coaling facilities of the port.



Outboard Profile of Fireboat to Be Built for New Orleans

New Passenger and Freight Ship is Under Consideration by New York and Porto Rico Line

Theodore E. Ferris, New York Naval Architect, Commissioned to Prepare Plans and Specifications—Bids May Be Asked in from Three to Five Weeks

THE construction of a new steel combination passenger and freight steamer is being contemplated by the New York and Porto Rico Steamship Company, according to official information obtained by Marine Engineering and Shipping Age. Theodore E. Ferris, naval architect, of 30 Church Street, New York City, has been commissioned to prepare plans and specifications and it is probable that bids for the contract will be asked in from three to five weeks. It is believed the cost of the proposed vessel will be close to one million and a half dollars, at present prices of materials.

According to preliminary figures, the ship will be about 425 feet in length, propelled by turbine engines of sufficient power to develop speed of 15 knots. Accommodations will be provided for approximately 200 first and 60 second class passengers, the public rooms and other equipment being designed for the maximum of convenience and comfort.

The new steamship will be of a type similar to the company's ship *San Lorenzo*, now being reconditioned at the plant of the Sun Shipbuilding Company.

Government to Order New Steam Driven Tender

BIDS will shortly be invited by the Bureau of Lighthouses in Washington, D. C., for the building of a new steel, stern-wheel tender for the Ohio and Monongahela Rivers, with headquarters at Cincinnati, Ohio.

The new vessel will replace the *Goldenrod*, now operating in these waters, and will be named the *Greenbrier*. She will be 165 feet overall, 140 feet length of hull, 32 feet 6 inches beam over the guards, and will draw 32 inches when in light steaming condition, 42 inches when fully loaded.

The motive power will be furnished by two horizontal high pressure steam engines operating at 200 pounds working pressure and horizontal flue boilers with natural draft.

Steam heating, hot and cold water service, electric light and steam steering gear will be provided. A noticeable feature in the design is two kerosene burning ranges in the galley, the use of which eliminates much of the heat of coal ranges and avoids the carrying of hard coal for cooking.

Reconditioned Fireboat Passes Successful Tests of Equipment

TESTS held recently on the New York fireboat *Thomas Willett*, at the Clinton plant of the Todd Shipyards Corporation, were pronounced highly satisfactory by Fire Chief J. J. Henry, consulting engineer of the department.

The *Thomas Willett* has just had new turbines and pumps installed by the Todd Corporation, and in the presence of expert engineers from the fire department, the National Board of Underwriters and Clinton Dry Docks, Inc., the boat gave a performance that Chief Henry said was better than he had ever seen in his thirty years experience.

At a pressure of 300 pounds, the pumps discharged 4,700 gallons of water per minute; at a pressure of 175 pounds, the pumps delivered 7,500 gallons per minute; at a pressure of 150 pounds, the pumps delivered 9,200 gallons of water per minute.

The fireboat's three turrets threw a 3-inch stream a distance of 400 feet, and with six stand pipes in operation six 2-inch streams of water were thrown a distance of 200 ft.

Those present at the tests, which lasted four hours, were:—Chief E. J. Worth, Chief J. J. Henry, Herbert Tracey, Fred Thompson, Lieut. George McNear of the New York Fire Department, F. A. Raymond, N. N. Walpert, H. E. Newell of The National Board of Underwriters, Paul D. Goodman, J. Hollander, W. F. Mayer, George Worley, Frank Howell, George J. Robinson, Frank Taylor, Joseph Haig and J. Herbert Todd.

Johnson Plant to Build Fireboat for New Orleans

THE Johnson Iron Works, Dry Dock & Shipbuilding Company, Inc., of New Orleans, La., has been awarded the contract for the construction of a steel screw fireboat for the city of New Orleans at a price of $264,447, the vessel to be completed in 220 days. Bids for the construction of this boat were opened on June 29.

The vessel will be 138 feet 6 inches long, driven by compound engines with cylinders 20½ inches and 46 inches in diameter and 28 inches stroke, steam being supplied by two watertube boilers, fitted to burn oil for fuel. She will be equipped with four turbine-driven fire pumps of a combined capacity of 10,000 gallons per minute and was designed by and will be built under the supervision of Cornell and Matthews, naval architects and marine engineers, of Philadelphia.

Contract for Three Tugs Goes to Tebo Plant

Orders for the construction of three steel, single screw tugboats for the New York Central Railroad have been placed with the Todd Shipyards Corporation, the lowest bidder. Construction will be commenced within a few days at the Tebo plant, in Brooklyn, and delivery is expected to be made by the end of January, 1923.

The boats are to be oil burning equipped with Todd mechanical oil burners. They will be 108 feet overall length, 25 feet 6 inches beam, 12 feet 9 inches molded depth.

Business Address

The Mahr Manufacturing Company, of Minneapolis, Minn., makers of the "Mahrvel Line" of oil burning equipment, have arranged to have W. H. White take care of their New York business. His offices are located at 56 Murray street, New York.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Steamer Repairs, Portland, Ore.—The American-Hawaiian steamer Iowan was awarded to the Albins Marine Iron Works, Portland, Ore., for repairs.

Steam Schooner's Hull Repaired, West Coast.—The schooner Virginia Olson has been removed to the Bethlehem Shipyards to repair the damage done to her hull in collision with a submarine.

Drydocking of Steamer, San Francisco, Cal.—The steamer Johanna Smith called at San Francisco, Cal., en route to Oregon from San Pedro to go on dry dock for annual inspection and repairs.

Contracts Awarded by Shipping Board.—The Shipping Board awarded repairs to steamship Chappaqua to Maryland Dry Docks Company at $868, repairs to Standard Oil Company's tank barge American to same plant at $2,647.

Repairs at Moore Yards, Oakland, Cal.—Steam schooners Arctic and Pasadena, barkentine James Johnson and lightship No. 76 went on Moore ways for cleaning, painting and repairing.

Condenser Repairs to Steamer, Savannah, Ga.—The Wilkinson Machine Company, of Savannah, Ga., repaired condenser on Edward Munch, a sugar vessel, discharging cargo of 30,000 bags of raw sugar at the refinery, Savannah.

Steamer Overhauled, Savannah, Ga.—The same company was also awarded the contract for generally overhauling the Farnsum.

Tanker Overhauled, Portland, Ore.—The Union Oil Company's tanker Oleum, which lost two propeller blades while en route up the Columbia River, was placed on drydock at Portland, Ore., for annual overhauling and inspection.

Tankers Overhauled for Renewed Service, San Francisco, Cal.—The Standard Oil Company has decided to place a number of their idle oil carriers in service again and has sent the tanker Algonquin to Union Iron Works docks for overhauling; S. C. T. Dood at Alameda for reconditioning, and F. H. Hillman to undergo reconditioning.

Ferryboat Completely Overhauled, San Francisco, Cal.—Ferryboat San Pablo was completely overhauled, inside and out, on ways of the Bethlehem Shipbuilding Company.

Overhauling and Repairs, San Francisco, Cal.—Tanker Richmond went to Union Iron Works for overhauling and freighter Bessie Dollar to No. 4 ways, for general repairs.

New Propeller on Steamer, Oakland, Cal.—Steamer Sonoma received new propeller at the Moore yards.

Contract Awarded, Pittsburgh, Pa.—Marine Manufacturing and Supply Company received contract to re-build sidewheel ferryboat Transit into sternwheel craft. New engines are 8 by 3, high pressure. The boat, built three years ago, is in Wellsburg, Ohio—Brilliant, West Virginia, trade.

Ship Overhauled, Pittsburgh, Pa.—Steamer Elizabeth Smith overhauled at landing of Marine Manufacturing and Supply Company, Pittsburgh, Pa.

Steamer Drydocked, Sun Yards, Chester, Pa.—British steamship Slavic Prince was drydocked at Sun yards, Chester, for miscellaneous repairs.

Repairs to Steamships, Mobile, Ala.—Steamships Maquan and Jeff Davis, consigned to Trosdal, Plant & Lafonta, underwent repairs.

Freight Carriers to be Reconditioned, Atlantic Coast.—Three freight carriers of 4,200 deadweight tons each, recently bought by the Matson Navigation Company are to be reconditioned on the Atlantic Coast before going into service between San Francisco and the Hawaiian Islands. They will be converted to oil burners. The steamers are the Coverun, the Cowee and the Cowboy.

Ship Repairs, Chester, Pa.—The steamship Agwimex, of the New York and Cuban Mail Steamship Company, went to the Sun Shipyard for boiler repairs, motor alterations and miscellaneous repairs to hull and engines.

Vessel Repairs, Hoboken, N. J.—W. & A. Fletcher Company, Hoboken, N. J., was awarded the steamers Clairmont for drydocking and painting; J. R. Gordon for general repairs, drydocking, and General Gorgas for drydocking, scaling underwater body, painting and repairing damage to bottom plates, the total amount involved being about $6,000.

Contract for Sea Dumper Scows, Brooklyn, N. Y.—W. H. Gahagain Company was awarded contract by City of New York for construction of twelve seagoing side dumper scows for use by Department of Street Cleaning. Unit bid, $40,992; total figure, $491,904.

Trial Trip of S-51, Bridgeport, Conn.—Submarine S-51, built by Lake Torpedo Boat Company, at Bridgeport, Conn., was officially turned over to United States Government by that company at Lake shipyard, Saturday, June 24.

Reconditioning of Steamer, Brooklyn, N. Y.—Robins Dry Dock & Repair Company, of Todd Shipyards Corporation, with a price of $229,000, was awarded contract for reconditioning steamship President Pierce.

Construction of Freighters, Sparrows Point, Md.—Contract for construction of two coastwise freighters for Eastern Steamship Line, Inc., Boston, Mass., was awarded the Bethlehem Shipbuilding Corporation at price of $287,000 each.

Contract Awarded, Cleveland, O.—American Shipbuilding Company was awarded contract by Prandas Steamship Company, of Cleveland, Ohio, for construction of steel freighter of 12,000 deadweight tons, similar to vessels shipyard now has under construction for other lake carriers.

Collier Contracted For, Midland, Ont.—James Playfair, of Midland, Ontario, has signed contract with Midland Contracting Company for construction of self-unloading canal sized collier.

Lighthouse Tender, Washington, D. C.—Bids to be shortly invited by Bureau of Lighthouses in Washington, D. C., for building of new steel, sternwheel tender for Ohio and Monongahela Rivers, with headquarters at Cincinnati, Ohio.

Two Ferries, San Pedro, Cal.—Los Angeles Shipbuilding and Drydock Corporation is to construct two steel, turbo-electric ferries. Construction contract amounts to $586,000 outside of equipment.

Overhauling of Steamship, Newport News, Va.—Newport News Shipbuilding & Dry Dock Company was awarded contract for overhauling steamer Middlesex, of Coastwise Transportation Company. Price, $134,986 (60 days).

Construction of Cargo Ships, San Francisco, Cal.—Bethlehem Shipbuilding Corporation has begun construction of two 20,000-ton cargo ships at their Union plant. These ships are to be combination ore and coal carriers similar to ore and oil carriers already built by that company.

General Repairs to Lighthouse Tender, Los Angeles, Calif.—Lighthouse tender Sequoia was taken to Los Angeles Shipbuilding & Dry Dock Corporation for hull scaling, painting and general machinery overhauling. Her service ranges from Panama to Alaska as lighthouse tender.

Contract Awards, Maryland.—Repairs to Atlantic, Gulf & Pacific steamer Cape Romain were awarded the Maryland Dry Dock Company, steamer Hoxie, of Baltimore Steamship Company's fleet, was docked at lower plant of the Bethlehem Shipbuilding Corporation, and barge Northern No. 44 was taken into upper dock.

Contract Awarded, San Pedro, Calif.—Shipping Board awarded contract for reconditioning steamers Huron and Aeolus to Los Angeles Shipbuilding Company. Total price, $137,928.

Steamship Conversion, New York.—Mallory Line contemplates converting steamer Medina from coal to oil burner.

Reconditioning of Steamer, Hoboken, New Jersey.—San Jacinto extensively overhauled, two new triple expansion engines installed and converted to oil burner; renovation of passenger accommodations, etc. Approximate cost, $700,000. Work completed by Tietjen & Lang Shipyards.

Probable Conversion to Motorships, New York.—Munson Steamship Company will probably convert recently purchased ships, two in number, to motorships. Expected the work will cost over $50,000 for each ship.

Morse Yard Receives Contract, Brooklyn, N. Y.—Morse Dry Dock & Repair Company, with price of $177,445, was awarded work of reconditioning steamer Buckeye State, following opening of bids by Shipping Board at 45 Broadway, New York.

Contract for Diesel Yacht, Newport News, Va.—Newport News Shipbuilding & Dry Dock Company awarded contract for construction of seagoing Diesel yacht, 172 feet by 26 feet by 12 feet. Vessel will be propelled by two 350 horsepower Winton Diesel engines.

Diesel Engine Installation.—William Cramp & Sons Ship & Engine Building Company equipped steamship Seekonk, recently purchased by them, with Burmeister & Wain engine. An order for two three-cylinder 125-horsepower mechanical-injection Diesel engines for ocean trawlers has been placed with the Atlas Imperial Engine Company by Western California Fish Company. Contract for the hulls was placed with the W. F. Stone & Son, Oakland, Calif.

Drydocking and General Repairs, San Francisco, Cal.—Coast guard cutter Seift went to Crowley's to undergo drydocking, general repairs and installation of new propeller. Army mine planter General Franklin K. Bell was also at Crowley yards undergoing a general overhauling.

Lightship Drydocked, San Francisco, Cal.—Lightship Blunts Reef was taken to Goat Island to undergo thorough cleaning and possible drydocking.

Savannah Concern Lowest Bidder on Government Dredges.—Wilkinson Machine Company, of Savannah, Ga., was awarded contract for emergency repairs on all of the government pipe line and seagoing dredges, operated in that district, at a price of $3,318.35.

Repairs to Steamer, Portland, Ore.—Steamship Santa Veronica was drydocked to replace a broken tail shaft and ship a new wheel at Portland Drydocks.

Wireless House Installed, San Francisco, Cal.—United States army transport Meiggs went to Crowley Shipbuilding Company to have new wireless house installed. Contract price for work was $5,100, and bid of Crowley Yards was lowest.

Contracts Awarded Fletcher Company, Hoboken, N. J.—Steamship Moldegaard, owned by A. H. Bull and Company, was taken to Fletcher yards for generally reconditioning; Eastern Dawn, of United States Shipping Board, for general overhauling; steamship Lebannon, owned and operated by Globe Line, for drydocking, examination and painting, etc.; Severance, owned and operated by Union Sulphur Company, drydocked, painted and generally overhauled; President Polk, owned by United States Shipping Board, for usual trip repairs. The yard also completed work of reconditioning steamship Philadelphia, formerly of the American Line, and now owned and operated by New York and Naples Steamship Company.

SHIPYARDS AND DRY DOCKS

Floating Drydock, etc., Guaymas, Manzanillo, Mexico.—Government of Mexico plans floating drydock, marine railway and repairing equipment. Price $1,000,000.

PORT IMPROVEMENTS

Dock, Saulte Saint Marie, Ont.—A. B. McLean & Sons, Saulte Saint Marie, plans dock for unloading sand and gravel. $60,000. Work will be done by day labor.

Pier, Oakland, Calif.—City of Oakland will build pier at the foot of Market street, by day labor under supervision of R. Beebee, harbor engineer. Price $200,000.

Pier Extension, Hermosa Beach, Calif.—Election is soon to take place on $500,000 bonds for numerous improvements, including extending present pier 300 feet into ocean.

Dredging, Manitowoc, Wis.—Contract for dredging 90,000 cubic yards in Manitowoc River was awarded to McMullen & Pitz, 915 Commercial Bank Bldg., at $0.305 per cubic yard.

Harbor Wall Repairs, Buffalo, N. Y.—Three breaks in the harbor wall south of the main entrance to Buffalo harbor are among repairs and improvements listed for this summer.

Dredging, Los Angeles, Cal.—San Francisco Dredge Company, San Francisco, Cal., was awarded contract for dredging about 670,000 cubic yards in Los Angeles harbor, San Pedro.

Wharf, etc., Norfolk, Va.—Contract awarded to Raymond Concrete Pile Company, 90 West street, New York, for 34 by 1,400 feet marginal wharf and pile jetty at Sewells Point, at price of $417,000.

Dredging, Los Angeles, Calif.—San Francisco Bridge Company, Nevada Bank Building, San Francisco, Calif., was awarded contract for dredging in Los Angeles harbor by U. S. Engineer, 725 Central Building, at price of $6,000.

Dredging, Chicago, Ill.—Fitzsimons & Connel Dredge and Dock Company, 10 South La Salle street, Chicago, was awarded contract for dredging in Calumet River, by U. S. Engineer, Room 1201, 537 South Dearborn street, Chicago, Ill.

Wharf, Midland, Ont.—Aberdeen Elevator Company, Midland, Ont., awarded contract for concrete wharf with 10 reinforced-concrete cribs and deck, to J. H. Tromanhauser, 69 Adelaide street, East Toronto, Ontario, Canada. Price $60,000.

Grain Handling System, Portland, Me.—Directors of Port of Portland, 67 Commercial street, Portland, Me., awarded contract for furnishing and installing grain handling system, to D. E. McIntire, Inc., 74 Broad street, Boston, Mass. Price $30,954.

Coal Pier, Virginia.—Virginian Railway will build a new coal pier at Seawall's Point terminals, more than doubling capacity of plant to dump coal. Expenditure will be about $3,000,000. Bids probably to be asked in near future. Preparing plans.

Harbor Improvements, Nassau, Bahama.—Taking bids for dredging channel and turning basin in harbor, 468,000 cubic yards of limestone and coral rock, 615,000 cubic yards of sand, low water depth 27 feet, tidal range 4 feet. S. H. R. Beard, harbor engineer.

Canal, Lake Charles, La.—Calcasieu Parish voted $2,700,000 bonds for deep water channel to the sea, including deepening and widening of Intracostal Canal between Calcasieu and Sabine Rivers, to depth of 30 feet and bottom width of 125 feet, also cut off near Lake Charles, and dredging Prien and Moss Lakes.

Dredging, Brooklyn, New York.—Sealed proposals were received by Superintendent of Public Works, Charles L. Cadle, at his office in the Capitol at Albany, N. Y., until twelve o'clock noon of Tuesday, July 25, 1922, for dredging a portion of the Henry Street slip at Gowanus Bay, Borough of Brooklyn, New York City, N. Y.

Bulkhead Platform, New York.—A. N. Spooner & Son, Pier 11, North River, were awarded contract by J. H. Delaney, Commissioner of Docks, Pier "A," foot of Battery place, North River, for a bulkhead platform between foot of Stanton and East Third streets, at $98,400; dredging thereat, to Morris & Cummings Dredging Company, 17 State street, at $0.28 per cubic yard.

Canals Purchased by Government.—Purchase by the Federal Government of the Cape Cod and Dismal Swamp canals, now privately owned and operated, is authorized under a Senate amendment to the rivers and harbors development bill adopted recently by the Senate Commerce Committee. Under terms of the amendments the Government agrees to pay $5,000,000 cash and to assume bonds aggregating $6,000,000 face value for the Cape Cod Waterway. The Dismal Swamp Canal, which runs from Chesapeake Bay to Beaufort, N. C., would be purchased for $500,000 under the amendment.

GOVERNMENT WORK

Bulkhead Extension, San Diego, Calif.—Specification 4651—Bureau of Yards & Docks, Navy Department, Washington, D. C., awarded contract for concrete bulkhead at Naval Base, San Diego, to Ross Contracting Company, Van Nuys Hotel, Los Angeles, Calif. Price $69,644 (120 days).

Seawall, Annapolis, Md.—Specification 4621—McLean Contracting Company, Fidelity Building, Baltimore, Maryland, was awarded contract for building seawall at Naval Academy, Annapolis, Md., by Bureau of Yards and Docks, Navy Department, Washington, D. C. Price, $14,350 (120 days).

NEW INCORPORATIONS

Gulf & Steamship Company, capital $75,000, chartered at Dover, Delaware.

The Augusta Navigation Company, capital $10,000, chartered at Wilmington, Delaware.

Observation Steamship Company, of Manhattan, capital $15,000, chartered at Albany; incorporators, E. F. Walker, H. F. Eckhardt and C. A. Polling.

The Pacific Fruit Transport Company, of New York, capital $15,000,000, chartered at Dover, Del., to operate steamships. Registrar & Transfer Company, Dover, Del., registrars.

The Shippers Exchange & Trading Corporation, of Manhattan, capital $100,000, chartered at Albany. Incorporators are V. and P. Giordano and C. R. Menille; J. M. Nolan, attorney.

American-Ukranian Corporation, of Manhattan, capital $50,000, chartered at Albany, New York, to do trade and transport business. Incorporators: W. B. Devoe, R. R. Maiden, H. S. Bracken.

Mexican Trading & Transportation Company, capital $100,000, chartered under Delaware laws, to engage in operation of boats. Corporation Trust Company of America at Wilmington, registrar.

The Backman Towing & Transportation Company, of Manhattan, capital $25,000, chartered at Albany, New York. Incorporators are: M. Anderson, E. Vorwerk and C. Backman; F. S. Johnson, 30 Church street, New York City, attorney.

Marine Equipment Company, Aberdeen, Washington, capital $1,000,000, organized for manufacture of ship furniture and furnishings. The new concern has purchased a tract of land east of Gray's Harbor and will shortly let the contract for the first unit of the factory building. New concern is only one of its kind in the West. Incorporators are: A. F. Gross, A. Bullinski, William Matis and John Trohimovich, of Aberdeen, and B. P. Kolowski, of Portland.

FOREIGN ACTIVITIES

Steamship Lines Established, Russia.—Odessa-Varna, Odessa-Constantinople, Odessa-Cardiff, and a further line between Odessa and an English port are to be established from Russia.

Tanker Launched, Caen, France.—Launching of what is said to be largest tanker in European continental yards took place at Caen, France. Vessel is 468 feet long, of 57 feet beam, with tonnage of 11,000. Named St. Boniface.

River Barge, Flardinsveld, Holland.—The Menvede Shipbuilding Company, late Van Vliet and Company, of Flardinsveld, launched a river barge of about 850 tons deadweight for Dutch owners, following which a keel for a sister-ship for the same owners was laid.

Monthly Passenger Service, France and Australia.—French-Australian Line has inaugurated new monthly passenger service between Marseilles, Melbourne, Sydney and Noumea, of New Caledonia. Company proposes placing seven or eight passenger and cargo steamers on route.

Steamship Launched, Holland.—Steamship Flandria, built for the Royal Holland Lloyd by Barclay, Curle & Co., Ltd., was successfully launched from the firm's Clydeholm yard, Whiteinch. This vessel, 470 feet long by 59 feet by 45 feet, with gross tonnage of 10,000, is for the Holland Lloyd's mail and passenger service between New Amsterdam and South American ports.

New Cargo Steamer, Holland.—The Kertosomo, the new Rotterdam Lloyd cargo steamer, built by Royal Shipbuilding Company de Schelde, Flushing, carries 3,000 deadweight tons on Summer freeboard. She is a shelter-deck steamer with forecastle, short bridge and cruiser stern. Principal dimensions are: Length, 473 feet 8 inches; breadth, 63 feet 4 inches, and depth to shelter deck, 41 feet.

Italian Shipbuilding Output.—During the first three months of the present year, the Italian Shipyards launched ten vessels of 13,743 tons. Of these five were passenger vessels of 11,788 tons, two sailing vessels of 560 tons, and five miscellaneous craft of 13,095 tons. During the same period keels were laid for one passenger steamer of 5,300 tons and one sailing vessel of 118 tons.

Steamer Launched, Belfast, Ireland.—The first-class passenger steamer City of Nagpur, designed and built for City Line fleet of Ellerman's Line, Ltd., was launched at yard of Workman, Clark & Company, at Belfast. The vessel is especially designed for passenger service between Great Britain and India and is twenty-first built by Belfast concern for Ellerman's. The vessel is more than 400 feet long and of 10,200 gross tons.

New Service, England.—November 4 will mark the beginning of a once-a-month service from British ports to Barbados and Trinidad by Elders & Fyffes, Ltd. It is proposed to arrange outward sailings in relation to sailings of the Harrison Liners Intaba and Ingoma, so as to give the West Indies a fortnightly passenger steamer service from the United Kingdom during the winter months. The Ingoma is to sail from Tilbury on or about November 18.

Scottish Shipbuilding.—During June the output from the Clyde shipbuilding yards aggregated 34,891 tons, compared with 40,476 tons in the same month last year. The half-year's total for 1922 is also down considerably, the figures being 162,216, as against 237,371 in 1921. From all the Scottish yards the June output amounted to 18 vessels of 38,240 tons, compared with 25 vessels of 42,651 tons during last June. The half-yearly total for all the Scottish yards amounts to 75 vessels of 180,270 tons, compared with 155 vessels of 275,370 tons during the same period last year.

Vessel Launched, Scotland.—Messrs. Ramage and Ferguson, Leith, have launched the steamer Tasso, built for the passenger and cargo trade between Hull and the Baltic of Ellerman's Wilson Line, Hull. The vessel is 344 feet long, 42 feet 9 inches in breadth, and 22 feet 6 inches molded depth. She will accommodate 45 first class and 362 third class passengers. The vessel is of cruiser stern type with extensive gear for rapid handling of cargo. Triple-expansion engines, having cylinders 21½ inches, 36 inches, and 63 inches in diameter respectively, and a stroke of 42 inches, will be provided by the builders. Two large Scotch boilers, working at a pressure of 225 pounds and fitted with forced draft, will supply steam.

Trial Trip, England.—Steel screw steamer Eastmoor, built by the Northumberland Shipbuilding Company, Ltd., Howden, to the order of the Moore Line, Ltd. (Messrs. Walter Runciman and Company, Ltd.), Newcastle, left the Tyne on her trial trip recently. The Eastmoor is 415 feet long by 53 feet breadth and 35½ feet depth molded. She will carry about 9,200 tons deadweight and has been built to Lloyd's highest class. Propelling machinery supplied by North Eastern Marine Engineering Company, Ltd. Triple expansion engines have cylinders 27, 45 and 75 inches diameter by 51-inch stroke, with three boilers, 15 feet 9 inches by 12 feet, 180 pounds working pressure, with Howden's forced draft. Trial was satisfactory, and mean speed of 11 knots was attained.

TRADE PUBLICATIONS

Heating and Power Plant Specialties.—The McAlear Manufacturing Company, 1920-7 South Western Avenue, Chicago, Ill., have ready for distribution a new 128-page catalogue, known as No. 27, which illustrates many new devices, including an individual temperature control valve, specialties for all power plants, vacuum and vapor heating systems, oil refining and water works plants, plumbing systems and marine service, together with illustrations showing their application and use. The individual temperature control valve is self contained and can be applied to any radiator, old or new, without additional piping other than the supply and return. When the thermostatic member is set for the desired room temperature, it automatically controls the opening and closing of the valve. The catalogue contains a very comprehensive detailed description of all specialties.

Vulcabeston.—The Johns-Pratt Company, Hartford, Conn., has just distributed its first catalogue which deals exclusively with Vulcabeston products, which include various forms of air pump, rod and valve stem, asbestos packings, pump valves, disks, bushings, rings, gaskets, washers, etc. Complete descriptions of the various products, together with price lists, are included in the pamphlet.

Seamless Steel Tubes.—The first of a series of illustrated bulletins, describing the manufacture of seamless steel boiler tubes, has been published by the Standard Seamless Tube Company, Pittsburgh, Pa. This first bulletin includes the manufacturing processes up to the point of piercing the solid billet and by means of illustrations gives an excellent idea of the equipment and methods employed. The second of the series of bulletins will be published within a short time, showing the tube mill operations, including the piercing of steel billets.

Fuel Oil Burning Systems.—A catalogue, consisting of three bulletins describing mechanical fuel oil burning systems and fuel oil burners in which the oil is atomized by low or high pressure air and steam, is being distributed by Schutte-Koerting Company, Philadelphia, Pa. The catalogue discusses thoroughly the installation, operation and maintenance of oil burning equipment, the characteristics, requirements and functions, as well as the relative merit of mechanical spray oil burners, the use of air control registers, oil pumping outfits and fuel oil heaters. Instructions are given for the general arrangement of steam boiler furnaces for burning oil.

Preventing Corrosion of Boiler Tubes.—A complete treatise in bulletin form on the prevention of corrosion in boiler tubes has been published by the National Tube Company, Pittsburgh, Pa. The subject of corrosion in general is treated, followed by details showing how this expensive item of locomotive boiler operation may be eliminated or reduced. This section includes methods of treating feed water, types of repairs and the like. The problem in the case of power and heating boilers is less difficult to remedy than for locomotives, being mainly a case of proper purification and softening of the feed water. In marine boilers the treatment of feed water is much the same as in stationary units. Authorities on the subject of corrosion have collaborated in preparing material for this bulletin.

Pneumatic Tools.—Two folders (special publication No. 686) have been sent out by the Chicago Pneumatic Tool Company, showing by illustration and description the great number of possible applications of the company's pneumatic and electric tools. These bulletins constitute a general review of riveting and chipping hammers, grinders, drills, air hoists, compressors, Semi Diesel oil engines and other products, with interesting notes on the history and development of the company and its devices, together with statements on the performance of many of them.

Flue Gas Analysis.—A new type gas filter for preparing flue gases for analysis, known as the double disk "Pyro-porus" filter, is described in a bulletin recently issued by the Uehling Instrument Company, Paterson, N. J. In addition to the details of the filter, an outline of its installation and uses are given, together with illustrations, showing its position in relation to the gas sampling pipe and boiler.

Armstrong Stocks and Dies.—Catalogue No. 17 has just been published by the Armstrong Manufacturing Company, Bridgeport, Conn., giving detailed descriptions and prices for Armstrong stocks and dies, water, gas and steam fitters' tools and pipe threading machines. A special section of the catalogue is devoted to details of new machines for threading and cutting pipe. These are built in various sizes for both hand and power drive.

Powdered Fuel Equipment.—A catalogue having as its object the explanation to prospective users of the advantages, construction and operation of the Grindle powdered fuel system has been published by the Grindle Fuel Equipment Company, Harvey, Ill. The complete system of stowing, drying, pulverizing, conveying and burning coal eliminates all handling of fuel by hand, shovels, wheel barrows, or industrial coal cars, also firing tools, grate bars, etc. The catalogue contains specifications and illustrations of standard equipment, but special types can be furnished to meet any particular condition.

Boiler Tube Cleaners.—The problem of eliminating the heat waste due to the formation of scale in boilers is dealt with at length in a catalogue sent out by the Liberty Manufacturing Company, Pittsburgh, Pa. Water turbine cleaners of various types, equipped with different style heads are described with the special uses for which they are best adapted. Pneumatic cleaners of high power in which steam can also be used are also illustrated and described. Mention is made of pneumatic cleaners for fire tube and return tubular boilers, arch tube cleaners and special cutting heads.

MARINE SOCIETIES

AMERICA

American Society of Naval Engineers
Navy Department, Washington, D. C.

WE GUARANTEE that of this issue, 5,250 copies were printed; that of these copies 4,196 were mailed to regular paid subscribers, 110 were provided for counter and news company sales, 231 were mailed to advertisers, 29 were mailed to employees and correspondents and 684 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 49,500—an average of 5,500 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Prod the Party in Power Into Action

IF there is one fault of the American people that is more outstanding than any other, it is their lack of interest in their own Government. Intense attention to business, which has resulted in the development of the resources of this country far beyond that of any other has left them with little time or inclination to "Render under Cæsar those things which are Cæsar's." The payment of taxes is not a citizen's whole duty. He must be prepared to vote intelligently and to help form a public opinion that will in no wise leave Congress in doubt as to the wishes of their constituents.

It is a favorite pastime to criticize our legislators particularly along the line of inaction, but, where there are so many divergent interests, it cannot be expected that any set of men can hope to read public opinion correctly, if America is to continue apathetic on questions of vital importance.

There can be no reasonable doubt that the vast majority of our people want to see our merchant marine firmly established and developed. A good many, however, are not convinced that a subsidy is the only way in which this can be accomplished. They know in a general way that our ocean-going shipping was practically negligible in 1914 and that later it was necessary to spend enormous sums of money in hurriedly constructing vessels to take the place of those being sunk by the German submarines.

The necessity for a merchant marine was apparent then but the reason why there was not an adequate number of American ships and the reason why millions of tons of our vessels are tied up today has really never sunk in because the interests who handle this business have taken good care to confuse the issue.

It would seem that our experience in the last sixty years of trying to build up and operate a merchant marine without Government aid would be convincing enough. It would seem that with fully one-half of the world's idle tonnage American owned while only one-fifth of the world's tonnage is under the American flag would show us that we are not getting anywhere near our share of the world's commerce. But this is not sufficient and, if the American people do not take enough interest to demand and insist that their representatives grant National aid of a nature similar to that which has been recommended by the best experts in the country, we will never have a merchant marine.

The subsidy is the answer until someone can show another way to make up the differences between the wages of the shipyard workers and the operating costs over that of other countries. The opponents to the shipping bill in Congress are not anxious to bring the matter to debate. They would far rather delay action on the bill and allow it in that way to die a natural death. But, if public interest could be aroused sufficiently to demand a decision on this matter, at this session of Congress, we need have little fear for the future of our merchant marine.

Standards for Export

ACCORDING to a report from the American Engineering Standards Committee, Germany is trying to impress its standards on all import countries. "The day may not be far distant," it is stated, "when American manufacturers will receive inquiries from oversea countries to furnish goods according to the German national standards, and it behooves us to plan in time to meet such conditions."

As an instance of how a standardized industry could be made of great value in securing foreign trade for Germany, a case is cited where "nineteen German manufacturers and one Swedish manufacturer were executing an order for seven hundred locomotives for Russia, all of the same design. Every part in every one of them was being made interchangeable with the corresponding part in all the others, all parts having been manufactured to the same fits and tolerances." This feature, it is claimed, "will have the great advantage of permitting the Russian railroads to use

any disabled locomotive as a store of spare parts for all the others. In one case a locomotive was assembled from parts machined in twenty different shops, with no more difficulty than a locomotive which was built complete in one shop."

Of course the inference is drawn that any future orders for locomotives from Russia will be strictly according to the design for these seven hundred engines which are built to German specifications and therefore German manufacturers will have a great advantage over those of other nations. It is not clear, however, what action should be taken by America to prevent the loss of foreign trade through Germany and England forcing their standards on other countries.

This much, nevertheless, is certain that we have the largest domestic market of any country to standardize for. Our export surplus which is claimed to be not over 15 or 20 percent on the average has all the benefit of quantity production and it is where mass production has been taken advantage of, as in the case of typewriters, harvesting machinery and automobiles, that we have achieved the greatest success in our foreign trade. It is our opinion that more could be accomplished for America at present by evolving some method of financing foreign trade but, at the same time, we should keep abreast of both England and Germany in the prevention of waste by standardization.

Shall We Depend on the British?

It has been stated that a much deadlier poison gas is now known than any which was used in the great war and that it can be put up in spherical glass containers of about 4 inches in diameter. One aeroplane could carry a sufficient number of these gas bombs to completely destroy all life in a city for the gas would remain in the narrow streets for days and would quickly permeate into cellars and subways.

We also learn that incendiary bombs of small compass but containing thermit have been invented. Anyone who has seen this substance used in welding operations will realize that it will burn its way through steel and cannot be extinguished. A shower of such instruments of destruction would be a catastrophe that Sodom, Gomorrah, Pompeii or Mt. Pelee could not eclipse.

Right here is the greatest argument for a ship subsidy. If such things are possible, we should not only have as good a Navy as any nation but a real merchant marine with its quota of fast passenger ships capable of making a speed of over 20 knots and so designed that they can be quickly converted to aeroplane carriers. We should make it certain that any fights in the future shall occur away from our shores and the only way to do this is to provide a sufficient subsidy to secure the construction and operation of the type of vessels that will not only help us commercially but also prevent terrible destruction in case of war.

Joseph W. Powell says that the Washington Conference clinched the supremacy of British sea power for the next decade. He is absolutely right, for England would still be mistress of the seas if every warship was sunk because her merchant marine and naval bases are superior in number and strength to those of any other nation.

England has constructed since 1905 twenty-seven passenger ships capable of making over 20 knots speed. All of these ships are over 10,000 gross tons. We have one vessel of 8,225 gross tons having a speed of 20 knots.

If we are going to have the protection of such vessels, they must be constructed, for they do not exist. The Shipping Board with all its surplus vessels has none. But, if a reasonable subsidy is provided, men like W. A. Harriman stand ready to do their part and this fact has been proved in Mr. Harriman's case by the money that he has already invested in American shipping.

Vote on Subsidy Bill Deferred

President Harding has agreed to a postponement of action on the Administration shipping bill until after the November election. But in doing so he has made it clear that he is still very much in earnest about the passage of this measure and that he still thinks it so important to our commercial prosperity and so essential for our national security that he sanctions the delay only because he fears that the attention of Congress cannot be riveted on the bill at this time.

Had it not been for the extraordinary industrial situation, namely, the coal and railroad strikes, which have taken practically his whole attention, the President undoubtedly would have invited conferences of the Congressional leaders to iron out the differences of opinion that have arisen in regard to the inforcement of prohibition on American passenger ships and other matters. But he believes that until a way can be found to straighten out these difficulties, so that they will meet the approval of all supporters of an American merchant marine, it would only jeopardize the bill by pressing for immediate action.

We are sorry that we cannot agree with the President's opnion that delaying action will help matters. We believe that the longer a vote is deferred the greater will be the opportunity for the alien propagandists and pacifists who make light of the necessity for a merchant marine as an auxiliary navy to defeat it. What a triumph it would be for those who are willing to place the United States in a position of dependence on the Navy and merchant marine of Great Britain to put American shipping in a position that it could take only such commerce as the other nations were willing to give it!

The President has intimated that should it become necessary to call a special session of Congress in order to get the subsidy bill written into the statutes he would do it. Let us hope that he meant what he said and that a special session will be called immediately after the election and kept in session until action is accomplished. History shows no example of a successful commercial nation that depended upon other powers for the carriage of its merchandise or for naval protection. If the subsidy bill is not enacted, American ships cannot compete with those of other nations and our prestige as a country will surely suffer.

No matter which way the election goes there will still be the same Congress during the short session commencing December 4. Therefore, President Harding with his unprecedented Republican majority in both houses of Congress ought to be able to make the subsidy bill a law even if a Democratic landslide occurs.

Boom for Shipyards If Subsidy Bill Passes

Cost of Subsidizing Ships Should Be Considered as Investment Paying Dividends in Increased Trade

By Hon. William M. Calder*

I ASSUME that no American citizen would oppose the creation of a great merchant marine. I know that all our people would like to see the ensign of their country floating at the masthead of ships in all ports of the world. But while it is pleasing to think of this, we must bring ourselves to the realization that its consummation can come only when we shall have adopted the means necessary to translate it into actual achievement.

It is a strange fact that some of our citizens who desire that America shall be supreme in the peaceful navigation of the seven seas would refuse to give their assent to the means through which this could be accomplished.

In reality the cost of the subsidization of the merchant marine would amount to nothing, for the benefits resulting from such an enterprise would be so great as to make the "investment" look trivial in the extreme. It is an investment which will pay enormous dividends in the shape of increased trade.

To embark upon an enterprise such as the President has already outlined would be to commit the country to an industry which before very long would become almost incalculably productive.

American shipyards would become more active than any of the plants on the Clyde, and soon we would have an army of trained and well paid mechanics who would rival anything that Scotland, England or Wales has ever produced.

Many of our citizens deplore the fact that less than twenty-eight percent of our commerce is carried in American bottoms, but when it is suggested that practically all American goods can be carried in American ships if we will only be wise enough to equalize the difference between the freight costs in foreign bottoms and American ships, they hesitate to take the steps necessary to assure such equalization.

They balk at the word "subsidy." Some of them even go as far as to say that it is synonymous with the term "graft." In reaching this conclusion they are deluded by an illogical method of thought. They forget that if their desires for an American merchant marine are ever gratified we must either pay American seamen the wretched dole that is given by European and Asiatic countries or give the American shipowner the benefit of Federal aid.

No one wishes to see the standard of living for American seamen reduced to the low levels of European and Asiatic standards. We all want American workers to be well paid, well clothed, and well fed. We want not only to build and operate a great merchant marine, but we want the ships manned by robust, wholesome men who are paid wages sufficient to enable them to lay up something against that time when adversity may overtake them. In other words, we desire that the American citizen who makes his living at sea shall enjoy the same benefits of his citizenship as his more numerous countrymen on land. It is worth paying a subsidy if only to assure the employment on American ships of men who truly represent American ideals. We want no impairment of American manhood whether that manhood is employed in the Arctic Ocean or in the congested cities of our great country.

Some of our farmers have criticized the proposal to build and operate a great merchant shipping industry through the temporary assistance of the government; and yet agriculture will be the chief beneficiary of such an arrangement. What farmer is there who does not desire that American fruit, American meat, American wheat, American corn and American cotton shall be carried to the ports of the world in American ships? Through the assistance given by the government, American ships will be able to enter into successful competition with foreign vessels and new and extensive markets will be found for American farm products.

Moreover, a merchant marine in time of war is an absolute necessity. The greatest navy that was ever built by any nation that ever existed, would be helpless without supply ships. The fighters must be fed. God forbid that we shall ever have another war; but if it should come, let us not be caught in the condition of unpreparedness in which we were found when the late struggle was forced upon us. I refer of course to our condition of unpreparedness in relation to necessary merchant ships.

It is humiliating to recall the fact that two-thirds of our soldiers were transported to France in British vessels. Our Navy convoyed them, and without the loss of a man, but we had to depend upon our chief associate in the war to get our men to the French front.

If the Germans had been successful in their submarine warfare, we would have been left with a great and efficient Army which because of the lack of necessary transportation facilities could not have taken, for a long time at any rate, an effective part in the terrible conflict. No doubt American genius, loyalty, patience and courage would at last have found a way to circumvent the enemy. But why allow ourselves to get into a condition where in time of emergency we are compelled to rely upon the shipping resources of another power?

I regard the general proposition of a ship subsidy plan in much the same light that I do the principle of a tariff to protect our American industries. Let us have a great merchant marine and be ready, as good and progressive American citizens, to pay the cost. The price will be comparatively small, while the ultimate returns will be incalculable.

* United States Senator from New York.

Ship Subsidy Vital to United States, Says Harriman

W. A. HARRIMAN, chairman of the United American Lines, declared recently in a newspaper interview that the position of American shipping is precarious. World trade is badly depressed, he said, and ocean rates are low and operating expenses high. Foreign shipping suffers from this condition, but American shipping suffers more because it costs more to run boats under the American flag, and because we have had less experience in world trade. The next five or ten years will be highly competitive ones and will test the strength of the shipping organizations of the various countries. Those which cannot compete will be forced to quit. Under these circumstances I consider the ship subsidy question a vital one for this country. If Congress sees fit to pass the subsidy bill, thus giving American shipowners assistance which is needed to see them through this critical period, I will then feel confident of the future.

Failure of Shipping Bill Means Government Ownership

If Merchant Marine Is Not Established Through Pending Legislation, It Will Be Maintained by Shipping Board

By "Old Scotch"

"WE will fight it out on this line, even if it takes all summer" was a declaration of General Grant in his campaign before Richmond. History records that it took him more than "All summer," but that eventually he won out.

The campaign for the subsidy bill seems to have resolved itself into a do or die proposition, and all the proponents of the pending legislation need is some of the indomitable spirit of Grant. Our cause is a just one, and notwithstanding the dismal outlook, at this writing, for legislation of any kind, we can console ourselves that the outlook is no more discouraging than that which faced General Grant, or similar outlooks of various other persons and classes in the world's history, who have accomplished great things by knowing that the causes which they espoused were righteous ones, and who had the will and determination to win because of that knowledge.

People generally have no use for "quitters," and, while I hesitate to place some of the proponents of the subsidy bill in that class, the fact remains that some of our number seem to be getting a little weak-kneed, to place it mildly. After all is said and done, what finite thing has developed to make any one weaken? The opposition to the bill in Congress is not based on the broad principle of a merchant marine or no merchant marine. Opponents have merely criticized certain phases of the bill, and made mountains from mole-hills of things which in a close analysis are more or less trivial. Such propaganda as has appeared in unfriendly newspapers is plainly based on the efforts of foreign rivals to defeat the bill and is disguised by American writers, who are not conversant with the subject, so thinly as not to hide its origin from readers who know the subject in all its phases.

Shall It Be Government Ownership?

There is one outstanding feature of the entire controversy that is so plain that it can be discerned by any one of fair intelligence and unbiased judgment, and that is, the American people at large are determined to have their own merchant marine. If it is not to be established through the medium of the present legislation before Congress, which represents the consensus of opinion of those best informed on the subject, there is little doubt but what it will be maintained as, at present, under Government ownership. The most bitter opponents of the subsidy bill have never questioned the idea of our having an American merchant marine, and no sentiment throughout the country has developed against that fundamental idea. So the alternative is, if this subsidy bill does not pass, we will find ourselves so firmly committed to Government ownership and operation that we cannot extricate ourselves from that much to be dreaded state of affairs.

There is in this country today a deep-seated leaning towards Government ownership of common carriers on land as well as on the sea, which should not be overlooked by those opposed to this semi-socialistic doctrine. Let our foreign rivals, who are trying their best to defeat the present bill, take heed of this warning. The very thing most dreaded in maritime nations abroad is that Uncle Sam will continue to operate his own merchant ships, if we can believe the editorial comments of leading journals. Hence, if by any chance they can succeed in defeating the subsidy bill, the avowed object of which is to place our merchant shipping in private hands, they will, beyond peradventure of a doubt, be confronted with a fixed determination on the part of this Government to continue in the shipping business as at present. The present Shipping Board has made gigantic strides in clearing up the fearful muddle in which our shipping was plunged during and just after the great war. Inefficiency, extravagance and downright crookedness have been almost entirely eliminated, and today the Shipping Board fleet is being operated almost as well as it could be in private hands.

Shipping Board Management May Appear Desirable

No one is making any money out of shipping at this time, because conditions of world commerce were never before at such a low ebb. Conditions cannot and will not long remain in this unusual state of depression. If freight rates, now lower than they have been in years, should advance to anything like normal, in all probability the books of the Shipping Board would show a small profit to the Government instead of the gradually decreasing losses at the present moment.

Efficient Government ownership and operation by the United States would be very difficult to beat by any foreign competition. Federal enterprises would not be compelled to show any financial profit, which would remove almost the entire handicap which surrounds private ship operation under Government ownership. The capital is already provided by the actual possession of the necessary ships, the cost of which, in the minds of the public at least, has already been charged off as a war cost. Depreciation charges just sufficient to provide the necessary replacements of more modern and efficient ships, of a number to equal the actual needs of transacting only sixty percent of our water-borne foreign commerce, the aim of our present shipping ambitions, would not be a great deterrent in a Government-owned merchant fleet. Honest and efficient management in the purchase of fuel and supplies, and the making of repairs, for such an enormous fleet such as we already have, under the present efficient Board, would be a great handicap for foreign competitors whose merchant fleets are divided up among innumerable private owners.

Big Undertakings Our Specialty

When it comes to quantity production and management the United States has always been supreme in any competition. The American mind seems to grasp great undertakings much better than any other, because we are all trained to think and act in large units. Nearly every one of the great basic industries upon which mankind's wants are filled are found in this country in a predominating state of development. Shipping, in the last half century, is the one outstanding exception to this general rule. When we start in to make this a success comparable to other great basic industries in which we are paramount, whether it be in private hands or by force of circumstances it is placed in public control, we can and will assume our rightful position.

We demonstrated what we could do in this line during the late war, when, waking from a somnolent state of our shipbuilding industry, we applied our national characteristics of energy and determination and in three years assumed the leadership in the world for ship production. Of course, due to the necessities of the world-wide strife, this great produc-

tion of ships was brought about solely by the Government, but it shows what we can do with our enormous resources and capabilities for tackling large jobs.

THE DIE IS CAST

There are but a very few Americans conversant with shipbuilding and ship operation who want to see our Government remain in the ownership and operation of merchant shipping. But the die is cast, the American public is awakened to the absolute necessity, for purposes of trade as well as of defense, of American control of a sufficient merchant marine for our needs in peace and war. If the opponents of the pending shipping bill can by taking advantage of legislative entanglements and political exigencies succeed in defeating the subsidy bill now before this Congress, there is but one inevitable alternative and that is a continuation of existing publicly-owned and operated shipping. The relief to the taxpayers, which is bound to follow improved conditions in ocean shipping returns, will convert many citizens to the continuation of the Governmental control of sea transportation.

It is needless to dwell on the tremendous effect such an unfortunate conclusion would have on that ever-present menace of Government-owned and operated railroads, and the eventuality of Government control of all means of transportation. The present deplorable mix-up between railroad owners and employees is daily adding fuel to the flames, and the long-suffering public may "first pity, then endure and then embrace" the temptation of what they may conclude is, after all, the only solution of transportation ills on land and sea.

PRIVATE OWNERSHIP DEPENDS ON SHIPPING BILL

It therefore behooves everyone of us who is not in favor of Government ownership of the means of transportation, and fortunately it is believed we are still in the great majority, to lend all aid to the passage of the subsidy bill, the only known means of placing our shipping in private hands at the earliest practicable time. The subject has been thrashed over and over for years by the best talent in the country, and the predominance of opinion, by those qualified to know, is that the bill as now drawn is the only method of accomplishing this aim. Discriminating duties, such as are now authorized by law, might have been the proper means for accomplishing the end, but that seems to be impossible of enforcement, so we will have to dismiss it.

The writer still believes that the administration bill can be enacted into law, despite the seemingly impossible tangle in which all legislation at this time appears. Worse predicaments than the present one in Congress have been ironed out by force of public sentiment. The subsidy bill should be passed before election day. Those in charge should not listen for a moment to the blandishments of half-hearted supporters nor to the threats of whole-hearted opponents. If action is postponed until "next session," as is now being advocated, the bill will fail and, failing in this Congress, a great step will have been taken towards Government ownership for sea and land transportation.

Foreign Dread of the American Shipping Bill

America, with Harbors Fronting on Two Great Oceans, Will Inevitably Become Greatest Sea Carrier, If President Harding's Bill Is Enacted by Congress

By Winthrop L. Marvin*

It is no disparagement of the pending shipping subsidy bill for the advocates of the measure to make it clear at the outset that they cherish no delusion that a great merchant marine can be created by the sheer force of National aid or subsidy alone. Encouragement to ocean shipbuilding and navigation is the universal policy of all nations having a sea front and a commerce. But it is not to be pretended that the amount of the National aid or of the subsidy is an unvarying measure of success attained. This success depends upon the native aptitude of each nation for maritime adventure and the degree of circumstances or conditions favoring it.

The British, pioneers in subsidies (to their great National mail lines), have been brilliantly successful. So has another insular race, the Japanese. This is not primarily because the British and Japanese happen to dwell on an island or islands. It is rather because both Great Britain and Japan are enterprising commercial and maritime peoples, having aspirations and resources for wide-flung seaborne trade.

These two nations were predestined for success upon the ocean. They have won that success with the help of persistent expenditures for the direct encouragement of their steamship services, and they have attained their object at no excessive cost. In their cases National aid, inherent aptitude and trade opportunity have coincided in a remarkable degree.

Take another example—that of France. The French have expended far more money in National aids and subventions than has Japan—partly because they began their policy of aid long before Japan did—in 1881 instead of in 1896. For a long time success with France hung in the balance. Her merchant tonnage did not increase at once, as Japan's did. This was in part due to imperfect methods of detail in French laws bestowing subsidies and subventions. But it ought frankly to be recognized that it was due also to the fact that France was not so distinctively a maritime nation and an expanding commercial nation as Great Britain or Japan, or, as we might well add, America.

France in the seventeenth and eighteenth centuries disputed with Great Britain the mastery of the seas. But France in the Napoleonic wars was beaten at sea as she finally was on land, and forced to a subordinate position in her navy and her merchant shipping. The French genius shone best in other lines of effort than in shipbuilding and navigation in the nineteenth century. France's population, moreover, became stationary and even declined, so that the nation lacked the vital stimulus of colonial expansion. Moreover, the products of French industry, while of high intrinsic value, are and have been of relatively small volume, thus failing to furnish the bulkier cargoes for the outward voyage. Further, France, since the war of 1870-1871, had no super-abundance of coal and steel for shipbuilding.

PERSEVERANCE BRINGS SUCCESS

Thus, because of basic reasons with which subsidy had nothing to do, the foes of National aid for some years after

*Vice-president and general manager, American Steamship Owners' Association, New York.

1881 were encouraged to point to France as an example of the ill-success of a subsidy system. But no thoughtful advocates of a policy of National aid by subsidy or in other ways had ever assumed that all nations that tried subsidy would succeed in equal proportion to the amounts expended. There is nothing magical in a shipping subsidy itself. To achieve the maximum results it must be joined with other factors of aptitude, enterprise, zeal and favoring conditions. France happened to face conditions many of which were unfavorable, and, therefore, because of the imperfection of her earlier subsidy laws as well as because of natural handicaps already outlined, her progress in the rehabilitation of her merchant shipping under subsidy was for a long time slow and discouraging.

But the French, a brave race, a gallant race, a patriotic race, steadily persevered. They revised and re-revised their shipping laws, attempted new expedients, ceased to favor sail ships at the expense of steamships, and generally learned wisdom from experience. As a direct result, French merchant shipping, which even with subsidy had increased only from 919,298 gross tons in 1880 to 1,350,562 gross tons in 1900, soon began to show substantial progress, gaining steadily from 1,350,562 gross tons in 1900 to 2,319,438 gross tons in 1914, the year of the world war.

Result Is Experienced Ship Operators and Shipbuilders

Even before the world war, France was indisputably becoming again a great maritime nation. In the four years of the world war 921,636 gross tons of French shipping were destroyed by the enemy mines and submarines. But the French system of National aid had developed excellent shipyards and a strong and capable body of merchant shipowners and operators—so that with the continued aid of the government the French merchant marine had more than made up its war losses up to a total of 3,245,194 gross tons in 1920.

That is to say, in spite of difficulties and discouragements under an improving policy of constructive National aid, the French subsidies had succeeded, as British subsidies and Japanese subsidies had succeeded, in making the French merchant flag a power on the ocean.

Those foes of National aid to shipping who had scoffed at France as an illustration of the "futility" of subsidies were utterly discomfited in the long run—precisely as had been those who in the United States fifty years ago had scoffed at any hope of success from the high protection to manufacturing, under which the United States has now become head and shoulders the greatest manufacturing nation in the world.

Now what had enabled France to realize her ambition for a merchant marine was not the subsidy alone, any more than it was the subsidy alone in the case of Great Britain or Japan. It was subsidy matched by high endeavor and sustained by the native producing and commercial resources of the nation.

An Impressive Lesson For America

These facts of recorded history have their impressive lesson for our America. National aid to shipping will succeed in the United States, as it has succeeded in Great Britain and in Japan, first because the American race, as its whole history proves, is by instinct and tradition a maritime race —judged by its achievements before 1861 the most daring and efficient maritime people the world has ever known. Moreover, the Americans, perhaps beyond all others an industrial and commercial people, are exporting today a greater bulk and value of home produced goods than any other nation—and our overseas trade is only as yet in its infancy.

There are in America the goods to carry and the genius to build and sail the ships to carry them. There is a rapidly expanding population to furnish shipbuilders and seamen to convey an ever-increasing surplus of products to foreign lands. Judging by the experience of Great Britain, of Japan and of France, the United States, once it bestows National aid on its shipping as a half century ago it bestowed most liberal National aid on its manufacturing, will succeed far beyond the measure of Great Britain or Japan or France, and will become, before many years have flown, the greatest merchant shipping power in the world, just as it will be incontestably the first and foremost of industrial and commercial nations.

Opponents Must Lack Common Sense

A few years hence there will be widespread wonder in this country that any men calling themselves Americans should have ever made the piffling objections that some of our public men are making to the enactment of President Harding's shipping bill. There will be amazement that any Senators or Representatives, even of States far inland, should have failed to visualize the tremendous opportunities which National aid to shipping opens not to shipping alone but to the manufacturing and the agriculture of America. Those who in the halls of Congress are now contending that America needs no ships and that subsidy will fail to give her ships, are going to be looked on presently like those other wiseacres who disputed with Columbus and insisted that he could not sail around the world to the Indies because the world was flat!

Let this fact be emphasized again and again, that it is only in the United States that there is any debate over National aid by subsidy or in other ways to shipping. When the British Parliament bestowed the hugest subsidy of all to the Cunard Line when it loaned twelve million dollars of money for the building of the *Mauretania* and *Lusitania* and provided a twenty-year subsidy by which the loan might be repaid, there were no protests from agricultural statesmen of the inland counties. The vote of Parliament was hearty and unanimous. Japan, since the war, has confirmed her long-time policy of shipping subsidies. France and Italy are doing the same. The Scandinavian countries are studying the best means of reinvigorating their merchant navies.

And they are all doing this without sectional or factional division. It is only in America that the appeal to sectional or party spirit is heard against National aid to the National flag in the most intensely competitive of international industries.

Anti-Subsidy Propaganda

Britons, of all kinds and degrees, as Senator Ransdell and other American public men have lately shown, are carrying on a vociferous campaign against any encouragement to American shipping. Tories, Unionists and Liberals, through their public press, are unanimous in the demand that the passage of President Harding's shipping bill must be prevented by the British government. They are appealing for the defeat of this bill to what they describe as the "pro-British party" in America. And the same spirit of violent antagonism to American aspirations on the sea apparently pervades the people and the press of all other maritime nations.

A minority report from five minority members of our House Committee on Merchant Marine and Fisheries proclaims that the proposed shipping bill will not create a great merchant shipping for America. On the contrary, all American maritime men and the Senators and Representatives from maritime States proclaim that this bill *will* create a great merchant shipping. With this informed majority of Americans, all British, Japanese and other foreign shipping men thoroughly agree. These foreign observers who know trade and who know ships are frank to confess that the American shipping bill is a tremendously formidable measure—that it will most certainly give America the mastery of the seas—and that all foreign interests must unite to obstruct and to kill the bill as soon as possible.

These foreign antagonists of ours see far more clearly than some of our own people that America, by her proved genius for shipbuilding and navigation, her unmatched commercial resources and geographical position, with her deep harbors fronting on the two great oceans of the world, will inevitably become the greatest of sea carriers if President Harding's plans are fulfilled by the American Congress. All the world sees this but some of our own far Southern and Western inlanders—men to whom the glorious facts of our maritime history are as if they never had been written.

Here, then, is the extraordinary situation as the time nears for active consideration of the American shipping bill—our foreign competitors frankly fearful of its enactment because they are certain that it will make America the first maritime power of the world; all Americans who know ships and sea trade absolutely agreeing with this opinion—and a minority of inlanders in our own country blindly striving to thwart America's destiny. Is not this a spectacle for gods and men!

A quarter of a century ago a similar spectacle might have been witnessed with regard to the American navy. Foreign governments frankly disapproved the building of the first White Squadron. Those foreigners objected strongly to the presence of American battleships and cruisers protecting American commerce on the highways of the world. A great many inland Americans also objected. Those first naval appropriations for a new steel fleet were passed on a narrow division, with the utmost difficulty. Yet where would we have been without this war fleet in our conflict with Spain? That was a revelation that converted the West and the South to the enthusiastic support of the American navy of today. And in the immediate future that is what our experience is going to be with the American merchant marine.

Latest Developments for American Marine Week

Prominent Speakers to Address Combined Gatherings of Maritime Associations—Model of Leviathan to Be Exhibited

As the number of days in American Marine Week, which will be celebrated at the Grand Central Palace, New York City, November 4-11, will be far too few to accommodate meetings and conventions for all the associations taking part, it is planned to hold combined gatherings at which prominent speakers will talk on the practical problems of American shipping.

Very interesting papers of this nature have been presented at the annual conventions of the National Merchant Marine Association in Washington and it is believed that the auditorium at the Grand Central Palace will be taxed to its capacity to accommodate all the members of the various maritime associations who will want to hear these instructive addresses.

Naval Architects' Convention November 8 and 9

Two days will be required for the reading of the technical papers at the annual meeting of the Society of Naval Architects and Marine Engineers. Professional men both here and abroad are interested in the subjects presented and the ensuing discussions because they represent the best that America has to offer in the science of naval architecture and marine engineering. The list of the papers and their authors has not as yet finally been determined but it is understood that the selection will be made about September 1.

Likewise neither the selection of the prominent speakers, who will address the practical meetings, nor their subjects can be definitely stated this month. They will include, however, prominent Government officials, Congressmen and the leaders of the maritime organizations. A number of these gentlemen have already signified their willingness to speak and the publicity value of their services to the American merchant marine cannot be over estimated.

Steamship Owners' Day

The quarterly meeting of the American Steamship Owners' Association will be held on Monday, November 6, which will be called "Steamship Owners' Day." This meeting will probably be held in the morning, as usual, and in the offices of the association, which will leave the afternoon and evening free to such of their members as care to attend the meetings at the Grand Central Palace and inspect the marine exposition.

Maritime Association

Mr. F. B. Dalzell, Jr., has been appointed chairman of a committee to represent the Maritime Association during the week. At this writing the other members of the committee have not been selected. When interviewed by a representative of Marine Engineering and Shipping Age, Mr. Dalzell stated that they expected to have a very fine exhibit in their three booths at the exposition. They will also be represented by one or more speakers.

New York Tow Boat Exchange

Mr. Dalzell, who is also connected with the New York Tow Boat Exchange, has secured from that organization the privilege of showing a valuable moving picture film of towboating in New York harbor. This film will be exhibited on several occasions during the week in the auditorium of the Grand Central Palace.

A Joint Meeting

Under the auspices of the Ocean Officers' Conference, composed of captains, mates, engineers and radio telegraphers, a joint meeting will be held in the auditorium of the Grand Central Palace. The exact date for this meeting will be announced later.

The Marine Exposition

One of the star features of the marine exposition will be a gigantic *Leviathan* exhibit, the equal of which has never been seen in this country before. Through the combined efforts of the Newport News Shipbuilding and Dry Dock Company and the American Marine Association arrangements have been made with Gimbel Brothers to exhibit the original model of the *Leviathan* at the exposition.

This model is the original model which was owned and built by the Hamburg American Line. It is said to be some 38 feet in length and without doubt it is the largest and finest ship model in the world.

Purchased by Gimbel Brothers

This model and a complete set of the original plans of the *Leviathan* were purchased in Germany by Gimbel Brothers who are the contractors for furnishing the stewards' equipment on the *Leviathan*, which is now being reconditioned at the Newport News Shipbuilding and Dry Dock Company for the United States Shipping Board.

This exhibition of the model at the Grand Central Palace, November 4-11, will be the first time it has been shown in this country. The model was recently shipped from Germany at great cost and arrived in New York on August 21, 1922. In addition to the fact that the model will show

all the details of construction to scale, it will be the first opportunity for the public to see what the underwater portion of the vessel really looks like.

Equipment Display

The gigantic *Leviathan* exhibit has been so planned that any concern furnishing material for the reconditioning of the ship may suitably display their part in the reconditioning of the world's greatest vessel, by exhibiting in this section.

Full particulars concerning arrangements to exhibit may be obtained from the office of the American Marine Association, Inc., 15 Park Row, New York city, telephone Barclay 5458.

Transportation Rates.

Mr. John A. Heuse, eastern manager of the Northern Fire Apparatus Company, has been appointed chairman of the Transportation Committee. He has started negotiations with the railroad men and the Trunk Line Association to secure reduced fare rates for all the members of the various maritime associations that take part in American Marine Week.

As soon as the details of just what formalities persons coming to New York to attend any of the functions must comply with are obtained they will be published. Instructions will be given about purchasing tickets and validating the same upon arrival at New York so that a half fare reduction may be secured. It will be a big saving to those who come from a great distance if the Trunk Line Association grants permission to the railroads to sell half fare tickets from New York to the home destination and would amount to 25 per cent of the entire railroad fare.

Sightseeing Trips.

It will also be the function of the Transportation Committee to arrange for comprehensive sightseeing excursions so that those who attend the exposition may have the opportunity of visiting all the points of special interest in and about New York.

A consolidated ticket office will be maintained at the exposition in order that all delegates may procure both railroad and Pullman tickets and make all steamboat reservations for the return trip without leaving the building.

Increased activity is being shown in requests for exhibit space at the exposition. Shipbuilders, repair and equipment companies from all sections of the United States will be represented at the show, according to present indications, and the exhibits being planned give promise of being more unusual and interesting than ever before. Steamship owners and steamship operating companies are also exhibiting a keen enthusiasm. The scope of the forthcoming exhibition is daily growing more widespread and the list of companies who will take part is being constantly added to.

The official allotment of space and booth numbers thus far made is as follows:

Booth No. 2—American Manganese Bronze Co., Holmesburg, Philadelphia, Pa.
3-6—General Electric Co., Schenectady, N. Y.
7—C. H. Wheeler Mfg. Co., Philadelphia, Pa.
8-11—Pneumercator Co., New York, N. Y.
12—Victor Eng. Co., New York, N. Y.
13—C. H. Woolsey Paint & Color Co., New York, N. Y.
15—Peabody Engineering Corp, New York, N. Y.
16—Texas Co., New York, N. Y.
17—McCormick, McPherson & Lapham, San Francisco, Cal.
19—American Steel Foundries, Chicago, Ill.
21—Ashton Valve Co., Boston, Mass.
22-24—Sperry Gyroscope Co., Brooklyn, N. Y.
25-28—Coffey Engineering Corp., New York, N. Y.
29—W. & J. Tiebout, New York, N. Y.
30—Pantasote Co., New York, N. Y.
31—Lee & Simmons, Inc., New York, N. Y.
32—Marine Review, Cleveland, O.
33—Hyde Windlass Co., Bath, Me.
34-35—Brunswick-Kroeschell Co., New Brunswick, N. J.
38—Crandall Engineering Co., East Boston, Mass.
42—The Babcock & Wilcox Co., New York, N. Y.
44—Underwood & Underwood, New York, N. Y.
45—Valentine & Co., New York, N. Y.
46—Port of New York Publicity Co., New York, N. Y.
47—Keasbey & Mattison, Ambler, Pa.
51—Marine Engineering & Shipping Age, New York, N. Y.
52—Mercantile Specialties Co., New York, N. Y.
53—Ellcon Co., New York, N. Y.
55—Northern Fire Apparatus Co., New York, N. Y.
57—Coen Company, San Francisco and New York, N. Y.
58—National Malleable Castings Co., Cleveland, O.
59—Scovill Mfg. Co., Waterbury, Conn.
60—The Griscom-Russell Co., New York, N. Y.
63—Diamond Power Specialty Corp., Detroit, Mich.
64—Asbestolith Mfg. Co., New York, N. Y.
65—Row & Davis, Engrs., Inc., New York, N. Y.
66—The Superheater Co., Chicago and New York, N. Y.
68—Crane Co., Chicago, Ill.
70—Bethlehem Shipbuilding Corp., Ltd., Bethlehem, Pa.
71—Sterling-Cooper Corp., New York, N. Y.
72—Bethlehem Shipbuilding Corp., Ltd., Bethlehem, Pa.
80—Newport News S. & D. D. Co., Newport News, Va.
81-82—Model of S. S. *Leviathan.*
83—Gimbel Bros., New York, N. Y.
84—Todd Shipyards Corp., New York, N. Y.
85—Westinghouse Elec. & Mfg. Co., East Pittsburgh and New York.
86—Marine News, New York, N. Y.
87—Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
88—Todd Shipyards Corp., New York, N. Y.
90—Chase Metal Works, Waterbury, Conn.
96—Marine Decking & Supply Co., Philadelphia, Pa.
99—Lunkenheimer Co., Cincinnati, O.
100—Worthington Pump & Machinery Corp., New York and Harrison, N. J.
101—Kingsbury Machine Works, Philadelphia, Pa.
107—P. S. Thorsen Co., Brooklyn, N. Y.
108—H. E. Boucher Mfg. Co., New York, N. Y.
111—B. F. Sturtevant Co., Hyde Park, Boston, Mass.
221—Masters, Mates & Pilots, New York, N. Y.
222—Ocean Assn. of Engineers, New York, N. Y.
223—Neptune Association, New York, N. Y.
224—American Bureau of Shipping, New York, N. Y.
225-227—Maritime Assn. of the Port of New York, New York, N. Y.
228—New Process Chemical Co., New York, N. Y.
229—American Society of Marine Designers, Quincy, Mass.
230—Check Room.
237-245—U. S. Navy.
246-248—Port of New York Authority.
249-270—U. S. Shipping Board.
273—Pioneer Company, New York, N. Y.
274-275—United American Lines, New York, N. Y.
277-287—U. S. Shipping Board.
288-303—U. S. Navy.
304—Crane Packing Co., Chicago, Ill.
316—Luckenbach Steamship Co., New York, N. Y.
327—Stamford Foundry Co., Stamford, Conn.
344-346—American Marine Assn., Inc., New York, N. Y.
347-349—Society of Naval Architects & Marine Engineers, New York, N. Y.

Inventor of Isherwood System Here

Sir Joseph W. Isherwood, inventor of the Isherwood system of ship construction upon whose patent about 12,000,000 tons of vessels have been constructed, arrived in New York on the *Majestic,* August 23. Sir Joseph will remain in the United States for a month or two as he has some very important business in hand. He will undoubtedly visit a number of the prominent shipyards.

Speaking of the voyage, Sir Joseph said, "just before leaving Southampton it was found that between 30 and 40 of the studs on the rotor of one of the low pressure turbines were broken. A special staff of about half a dozen extra engineers was taken on board in addition to a superintendent and it was decided to make the repairs on the trip.

"Working under conditions of extreme heat this wonderful feat of drilling out and renewing about 40 studs 1½ inches in diameter was accomplished in 30 hours while the steamer proceeded at about 17 knots."

Notes on Dead Freight, Detention and Demurrage

By Robert E. Annin

In this article Mr. Annin explains from a wealth of practical experience a number of the ordinary and extraordinary occurrences that are apt to prevent economy in turnaround. While the possible situations that may occur cover so wide a range that no treatise can be expected to supply a full set of precedents, nevertheless the examples given form a basis which supplemented by experience and common sense ought to be of great value in preventing the losses in ship operation that depend upon the period elapsing between a ship's entering upon and release from service.

THE chief protection against loss to the ship caused by shipper's or charterer's delay in the delivery or removal of cargo lies in the penalties known as dead freight, demurrage and detention damages. Broadly speaking, the first applies primarily to berth shipments, the second to charters and the third to special cases technically falling outside the ordinary provisions of the first two. Since delays cause irrecoverable losses to one or the other party in interest, there are no provisions of a freight contract which are more frequently the subject of acrimonious dispute and in the discussion of which novel technical positions are more frequently assumed.

The enforcement of full demurrage on the ship as a penalty for default in shipment or removal of parcel lots is of course ordinarily impracticable, since in a majority of cases the value of the cargo would be insufficient security for the demurrage claimed.

Further, to hold up an entire shipload for default on a parcel lot would be a damage to all non-defaulting shippers; and, if the ship be not actually delayed, demurrage cannot be earned.

Bill of Lading Requirements

Hence the ordinary bill of lading provisions for dead freight in case of shipper's default in delivery, and for delivery into store at cargo's risk and expense in case of failure promptly to accept and remove on discharge.

This is subject to the obligation of owner or agent to make every effort to reduce shipper's loss by filling the unused capacity in the open market. Nor may the ship take any action at port of discharge which shall cause *unnecessary* loss to the cargo owner.

To meet special conditions, special clauses are, however, often desirable on the bill of lading.

One very striking incident of this sort occurred shortly after the end of the great war. A certain shipper had made berth term engagements for full cargoes of general merchandise from the United States to Europe. No charter was made and the bill of lading contained the usual discharging clause.

Learning that the port of discharge was badly congested, the warehouses full and the wharves crowded with cargo, the carrier decided to protect himself with a special clause, fearing that such congestion, etc., might continue until the arrival of one or more of the ships. Clearly, if no warehouse or dock room, or even river or harbor craft should be available on arrival of the vessels, the carrier's right to discharge into store, etc., would be barren; and (no other recourse being stated in the contract) it might be that the consignees could use the carriers' property as a free warehouse and the latter have no remedy.

A Special Clause

To cover this possibility the following clause was inserted:

"Should consignees fail to remove cargo promptly and should storage room be unavailable, the carrier shall be entitled to damages for resulting detention to steamer, at the per diem rate of ——— U. S. gold per ton of steamer's net register; and the same shall be a lien upon the cargo until paid."

As it turned out, it was most fortunate that this precaution was taken. The port was in chaos on arrival of the ships, some of which were delayed over a month beyond a proper discharging time.

The case, however, differed from ordinary berth term shipments in that the complete cargoes were from one shipper and to one consignee. In the event of several shippers and more consignees any such clause would have been unworkable. Nor would such a provision properly fall under the head of demurrage, but rather of detention damages.

Record of Lay Days Essential

In ocean traffic demurrage is commonly to be considered in relation to voyage charters only, and since demurrage can only begin upon expiry of lay days as provided, an undisputed record of countable lay days is essential for the ship. Hence a proper charter form must clearly provide for the earliest day and hour at which days may begin to count; the exemptions (if any) agreed upon and the conditions which shall constitute a proper tender. The potential importance of an exact count from the beginning to the end of lay days is often overlooked. Let the charterer fulfil his contract by completing the loading before or by the expiration of lay days, and no question of demurrage may be brought against him. But if he delay the ship, if only by a few hours, any cause of delay developing between expiration of lay days and completion of loading, may involve a valid demurrage claim, even though the delay run to days or even weeks.

In such case the test question is apt to be—would the ship have met the delay, if the charterer had loaded her within the time granted in the charter party?

Examples That Might Result in Serious Demurrage

To illustrate,—should a ship whose days expired at noon on a Saturday be incompletely loaded at that hour, and a general dock strike develop on Saturday afternoon, the charterer would ordinarily be bound for all resultant demurrage even though the delay should be far in excess of the time required to load the ship. For the strike clause, like other exemptions of the charter party, can be claimed by charterer only during lay days.

Nor is it always possible for the charterer to accept loss by paying dead freight in lieu of completing the loading. In the case of a bulk cargo sold "10 percent more or less" it might be that the minimum quantity permitted by the contract of sale had not been loaded when the interruption occurred. The charterer would then have to choose between the payment of demurrage up to completion of loading, and jeopardizing his sale by tendering a quantity below the contract limit.

From such instances it is sufficiently obvious that demurrage and detention clauses cannot be considered too carefully, in relation to their potential relation to other charter clauses.

Tendering, Strike and Berthing Clauses

Closely related to this matter are the tendering, strike and berthing clauses. In relation to the two last, questions may

easily be raised in connection with conditions existing at the dock to which ship is ordered by charterer.

For the latter to select a wharf where loading was interrupted by strike, the claim benefit of the strike clause would be obviously unfair if other berths not so affected were available. Such a right if recognized would clearly be subject to grave abuse.

In such case, however, the owner or agent should refuse the berth when tendered. To accept the order to berth without demur might be considered as a waiver on the ship's part.

As a curious instance of the defenses which may be set up against demurrage, may be cited the case of a sailor in a South American port. Charter party obligated charterers to provide stiffening when and as called for by the master, as the ship could not shift or stand up without ballast. The stiffening was not provided in accord with contract terms and vessel was therefore delayed in discharging. Claim for demurrage was refused by charterers on the ground that the ship was not a good tender until discharged; that lay days could not therefore begin, and that no demurrage was due until lay days had run out. This was an ingenious method by which defendants endeavored to make their first default neutralize a subsequent delinquency.

The case was decided by awarding detention damages to the ship based on the rate of demurrage provided in charter.

An interesting detail was that charterer's agent had induced the master to sign a certificate which substantiated the charterer's claim as to days used in loading, but which the facts as established contradicted. The decision therefore supported the principle that a certificate of the master, not in accord with the facts proved or admitted, may be disregarded. But the main point decided was of course that neither party may claim benefit of a default of the other when same is directly due to his own delinquency.

Action to Reduce Losses to a Minimum Necessary

This leads to another point, not to be easily stated in a phrase, but of great influence in case of controversy.

In case of unforeseen and unforeseeable events, not specifically covered by charter provisions, the party observant must act so as to cause the least possible loss or expense to the party delinquent. As an actual incident:—

A ship, discharging at New York, had left in her 300 tons of ore, when a dispute arose resulting in the temporary holding of the ore by the carrier, as security for demurrage. The carrier had two courses.

First, to hold the cargo in the ship, charging against it the full amount of demurrage accruing day by day, or—

Second, to secure lighters and discharge into them; thus releasing the ship, and avoiding full demurrage as provided in the charter party, but making the cargo liable for lighter hire during the time that the dispute might continue. The second course was by far the less expensive, and the ship chose it.

But in the course of arbitration it developed that, had the other course been chosen, the ship could not have enforced a claim for full demurrage; on the ground that in case of default, the party observant is obliged to pursue the course obviously least damaging to the party delinquent, provided the security of the first party were not thereby impaired. In this case the security was the ore. If it could be held in barges at a cost of say $100 per day, it was the duty of the carrier so to dispose of it pending settlement; since the cost of demurrage on the ship itself would have been $750 per day.

Ready and Seaworthy

The question as to what constitutes readiness clearly has a vital effect upon possible damages for delay. Under long standing decisions of English law, it has been decided that readiness to load does not necessarily imply readiness for sea. This is also confirmed by universal practice; for few ships when tendered for loading fully meet requirements of seaworthiness as to provisions, crew and bunkers. As to engines and equipment the case is not so clear. Customarily, if a ship be tendered seaworthy as to hull, and with all holds ready to receive cargo, charterers do not object to minor repairs, not interfering with loading, whether to engines, decks or rigging. But a recent American decision held that a motor-schooner tendered on her cancelling date with engines in dismantled condition, justified charterers in cancelling the charter. Certainly in case it were doubtful whether engines could be made seaworthy by the time loading was complete, objection on the part of the charterers would seem to be justified.

Termination of Lay Days

Another question has been recently raised concerning the termination of lay days. A coal charterer, having delivered a full cargo of coal to a ship, claimed that lay days ceased with the arrival of the last coal in the hold of the ship and that time occupied in trimming was for the account of the owners. There appeared to be no precedent for this nor was the point directly covered in the charter. It had therefore to be argued from the lay day clause as written.

That clause stated: *"Cargo to be loaded at the rate of* 1,000 *tons per day;"* and the meat of the question (when it came to be considered) lay in the proper definition of the term *"loaded."*

When, therefore, is cargo loaded in the sense that the charterer's obligation in relation to lay days terminates? Charterers claimed such point to be reached when cargo was aboard ship; owners claimed that it was reached when cargo was aboard *and stowed.*

Trimming for coal is equivalent to stowage for most cargoes.

Now evidently in the case of general cargo, the "loading" is not complete either when the cargo is placed alongside ship (which constitutes *delivery* under most charters) nor even when it is taken aboard. Such cargo is only *loaded* when it is stowed and secured in the hold and the ship safe to proceed, so far as cargo is concerned. Hence, in general cargo, the term "loaded" means "put aboard and stowed."

Grain Must Be Stowed

In the case of grain, the cargo is delivered by shipper to the elevator, and the loading is by belt carrier or by gravity. The grain has to be trimmed, and a part bagged. The time required for bagging and trimming is always counted as part of the lay days in loading grain, and on the face of it, properly so. It would be a gross injustice to the ship merely to dump the grain in the holds, and claim that loading was complete. Therefore, in grain cargoes the term "loaded" means "on board and stowed." The same argument may be used in regard to lumber and other cargoes.

"But," said the charterers, "the trimming of coal is by contract paid for by the ship; and if the duty, responsibility and expense belong to the owner, the time also must be for owner's account. Also, suppose the coal lay untrimmed for a week; would that week count on lay days?"

The first of these points is covered by the analogy of general cargo, grain, and lumber. In all these articles, the cost of stowage is borne by the ship under ordinary gross form charters, but time spent in stowage counts on lay days.

The second point is only well taken in case the ship neglects, or for any reason does not use, due diligence in the trimming.

The conclusion finally reached may be summed up in the following: "and properly stowed; but the ship must use due diligence to complete stowage as promptly as possible during working hours. Any unnecessary delay in stowage or trim-

ming the cargo shall not count as lay days, or in demurrage, as against the charterers."

Delays Caused by Strikes

The so-called "Strike Clause" is likely to cause as much controversy as any other ordinary provision of a charter party. Stoppage of labor on wharves or lighters directly involved is simple enough. The term "extraordinary occurrence," which is often used, is not very conclusive; yet it is difficult to see how it can be expanded with any real advantage. What is an extraordinary occurrence? Let us say an occurrence which ordinary foresight and diligence could by no means have prevented or provided against. The Martinique volcano; the Galveston cyclone; the Great War; clearly would come under this definition; as might a disastrous fire or earthquake in New York, Norfolk, or San Francisco.

But these are all obviously extraordinary and would probably be covered by the "Act of God" etc. clause. The puzzling questions are those which come up when an occurrence is close to the line of ordinary or extraordinary; a gale in harbor; a fire or strike of limited extent but wide influence; a sudden change in law; or any other happening which one party may claim as coming within the limits of the ordinary, while the other asserts that it is in the class of the extraordinary. There seems no course here except to leave the definition open until the emergency forces a decision.

Direct Effect of Extraordinary Occurrences

This can be somewhat modified by the stipulation that such "extraordinary" occurrences must "directly" prevent the delivery, loading, or discharge, of cargo; and the effect of the word "directly" should not be overlooked. It is conceivable that a local coal strike might prevent the production of steel in certain mills; an automobile manufacturer being unable to obtain promptly steel contracted for with such mills, might be delayed in shipping an export order; and, further, transportation might be delayed by lack of coal. The result might be that a large percentage of a given cargo would be late in delivery and a ship therefore held beyond her lay days.

Clearly it would not be fair to the carrier to saddle the loss from such delay upon him.

Cases Where Charterer Is Responsible

Again, a local strike might prevent the delivery of the special lot of coal cargo contracted for, by the date which the steamer had been chartered to fit. Here might arise a question, provided other coal of suitable quality were not available. But if such coal were obtainable *at any price* it would appear that the charterer must be held responsible. Otherwise the owner in accepting charter terms would be assuming the guarantee of contract between the charterer and supplier in which he had no interest, and of the terms of which he was ignorant.

In the list of extraordinary occurrences which might raise debatable questions, the following will be pertinent. A shipper had engaged on berth terms, thirty loads of grain for shipment by three successive freight liners. All the grain was coming down by Erie Canal from Buffalo, and ample time had been allowed for the boats to reach New York. But one week before the first lots were due to arrive, a flood caused a break in the canal, holding up the entire shipment for over ten days, and there was no available grain of similar quality in New York.

No such clause as we are now considering was included in the freight engagement, and the carrier therefore had the shipper at his mercy. The matter was amicably and equitably arranged, owing to the liberality and large mindedness of the carrier. But it is no bad guess that, under full charter terms, many owners would have exacted their pound of flesh, unless checked by some such provision as we are now considering.

Experience Best Guard Against the Unexpected

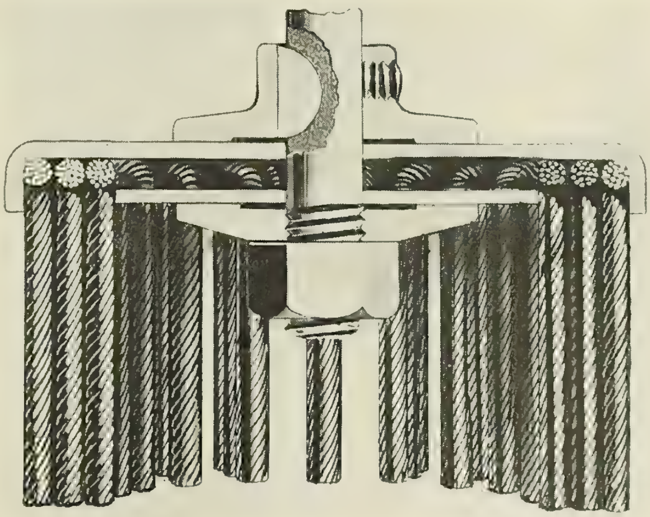
These are merely examples; and current charter forms are full of such clauses gleaned from experience. Hence it is the duty of the charterer to protect himself, by careful study of current practice, supplemented by any special experience of his own, against the unexpected and the unpredictable. Here is the great advantage of the owner or charterer experienced in certain trades. He will know of risks to be run, of contingencies to be provided against, and tricks to be dodged, which the novice (absolute or comparative) cannot possibly foresee.

Another principle which should be borne in mind is that in the absence of special covenant to the contrary, lay days always begin to count with the beginning of loading or discharging, notwithstanding any *general* provisions of charter party.

For these matters, which are of the very essence of the business, experience, aided by common sense, is the only true teacher. The possible situations have so wide a range that no records of the past can be expected to supply a full set of precedents. The vital importance of a correct estimate of the time required for a given service, is obvious in relation to arrangements of deferred business. Further, profit or loss on any gvien voyage depend largely upon the length of the period elapsing between the ship's entering upon and release from the service, since the ship's expense is in proportion to the time used. In the case of chartered ships this factor varies in importance according to the proportion of expense which the contract between the two parties imposes upon the shipowner.

Wire Brush Attachment for Air Grinders

In ship work where the removal of rust and old paint forms a very essential operation in the repair and maintenance of practically every vessel, the new wire brush attachment for air grinders produced by the Chicago Pneumatic Tool



Wire Brush for Attachment to "Little Giant" Air Grinders

Company, Chicago, Ill., will be found especially useful. This brush consists of three units, a 1/8-inch back plate, dished as shown in the illustration; a 1/8-inch front plate with a series of slots, and a wire brush consisting of 30 renewable units made of heat-treated crucible steel.

Recent Developments in Marine Insurance

River Plate Controversy—Cargo Clause Changed Protecting the Mortgagee—Carrier's Liability to Shipper—Standard Policy

By "Bordereaux"

ONE of the outstanding features of the past month in marine insurance has been the lively controversy that has developed with respect to the River Plate clauses. There is evidence of a concerted movement on the part of the banks to force underwriters to modify these endorsements and concede coverage on goods held in the custom house awaiting assessment of duties. The clause to which so much objection is being raised reads as follows:

Including (subject to the terms of the policy) all risks covered by this policy from shippers' or manufacturers' warehouses until on board the vessel, during transshipment, if any, and from the vessel while on quays, wharves, or in sheds during the ordinary course of transit or until safely deposited in consignees' or other warehouse at destination named in policy, except that in respect to shipments to the River Plate, the risks under this insurance shall cease upon arrival at any shed (transit or otherwise), store, custom house or warehouse, or upon the expiry of ten (10) days subsequent to landing, whichever may first occur.

The reason this discrimination had to be made against shipments to the River Plate lies in the fact that fires so continually broke out at the point involving the underwriters in a disproportionate number of claims.

The position taken in the revolt of the banks is as follows: The customs regulations of Buenos Aires require that all shipments arriving in vessels from abroad shall be declared within eight days of the entry of the vessel or pay a fine of 2 percent on the customs valuations. Due to the foregoing, the merchants of that market have grown to consider this interval as a period of grace, during which time they may accept or pay the relative drafts, and many of them invariably take the full eight days. At the same time, the banks which have received the bills for collection have also been in the habit of allowing these eight days to pass before making declaration and insuring the merchandise pertaining to items not attended to. They have been led to do this from the fact that formerly the insurance policies covered the goods for more or less time after unloading and placing in the Government warehouse, usually for a period longer than eight days, but when a special qualifying clause was added to the policies because of disastrous fires which took place in deposits their custom was not altered.

Cargo is not unfrequently landed and stored in a Government warehouse for several days before expiration of the above-mentioned period, and whenever this happens the goods remain unprotected until covered by fire insurance. For the banks to cover all shipments, the documents for which pass through their hands, on the day of entry of the vessel and attempt to collect the proportionate premium from the drawee of the respective bills would probably result in much trouble and argument for them, to say nothing of losses from delays in payment or acceptance of drafts. This attitude of the Buenos Aires banks is being brought to the attention of their correspondents in this country to the end that something may be done to cover this phase of insurance; for instance, that insurance policies may be adjusted to cover at least ten days in the customs deposits there, or that instructions may be given by the insurance companies to cover goods for account from the day of the entry of the vessel.

The underwriters, on the other hand, argue that it is not unusual for goods to be held in customs at the River Plate for thirty and forty days, and that such extended risks were not contemplated by them in their rate of premium; nor do they care to encourage such unnecessary and dilatory practice by granting coverage at a higher rate, although in most cases the shipper can arrange at the time of placing his insurance for a cover of thirty days after discharge from the steamer.

There would seem to be considerable merit in the contention of the banks that the clause of the underwriters should be so worded as to grant, say, not exceeding ten days coverage in the custom house and/or on the wharf instead of making the insurance terminate as at present. Under the regular warehouse-to-warehouse clause the risk in customs is covered during any period of ordinary transit. Indeed, unless some concession is made by the underwriters, it is evident that they stand a good chance of having this business lost to the American market, as the consignee is very likely to arrange for insurance in Argentina under his open policy. A marked tendency in this very direction has been observed of late in both Argentina and Australia.

New Cargo Clause Changed

WITH the evident intention of preventing ship owners and operators from evading any part of their legal liability Clause No. 9, of the new American Institute Cargo Form 1922, has been amended with the approval of underwriters to read as follows:

"Warranted that this insurance shall not inure, directly or indirectly, to the benefit of any carrier or bailee; and warranted also that the assured has not made and will not make any waiver or special arrangement with any carrier or bailee who shall have the custody of any goods hereby insured, releasing such carrier or bailee from its or his common law or statutory liability."

Protecting the Mortgagee

AMERICAN marine underwriters have concluded that they will in the future be obliged to scrutinize their hull coverages very carefully to make sure that their own interests are protected quite as much as those of the mortgagee, especially if the appellate courts of Great Britain sustain the recent decision of Justice Greer in the case of the steamer *Ioanna*. This vessel was of Greek registry and was sunk in the Mediterranean during the epidemic of Greek total losses. In the course of subsequent litigation it was established that the vessel had been deliberately cast away and not lost through a war peril, as alleged by the owners. The underwriters on the war risk were excused from liability, but the Justice held that they were liable under marine risks for an amount equal to the mortgage on the vessel. It was held by the court that the mortgagees were not responsible for the loss, as they had not connived with the operators. To protect them, the Justice ruled that the boat was lost by the entrance of water into the hold, and that is a marine peril. Marine underwriters insist, however, that the business of insurance ought not to be saddled with fraudulent losses for the sake of mortgagees who are not parties to the insurance contract. Unless the sinking of a vessel is an act of barratry, the risk, they insist, is not covered by the marine policy.

In this case of the *Ioanna,* as well as that of the *Gregorios,* a similar Greek loss, the case of Small vs. the United Kingdom Company was cited as a precedent, and apparently had considerable weight with the court. In this celebrated case the vessel was deliberately cast away. The offending master was part owner, but the other owner was innocent. Suit was brought by the innocent owner and he won his case on the contention that the co-owner had committed a barratrous act. Underwriters regard this as a bad precedent to have followed in the cases above referred to. That there is a wide variance of circumstances, the following summary by Gow, in his "Sea Insurance," proves: "Interests of mortgagor and mortgagee are distinct; master who is mortgagor can commit barratry against mortgagee, provided he was not appointed by mortgagee; policy effected by mortgagor; intention to benefit mortgagee."

Dry Dock on a Rampage

DRY dock underwriters had a narrow escape from a serious loss recently when the main dry dock of the Jahncke Dry Dock and Ship Repair Company, of New Orleans, broke loose from its moorings with the steamer *Nyanza,* of the Pacific Caribbean Gulf service, in dock. Scarcely had this steamer been admitted to the dock when the latter tore away from the wharf and started on a wild rampage down the river. It made an impromptu voyage of two miles before being captured by tugs. Fortunately, the *Nyanza* had been able to slip out without damage. It was astonishing that none of the shipping in the harbor was rammed by the dock; several vessels were missed by inches.

Liability of Carrier to Shipper

IN an interesting case recently decided by the United States Circuit Court of Appeals, Second Circuit (279 Fed. Rep. 684), several involved questions arose as to who was the insured and who the insurer. The Virginia-Carolina Chemical Company brought suit against the Chesapeake Lighterage and Towing Company for the recovery of damages alleged to have been sustained in the total loss of certain merchandise of the former carried on a barge of the latter, which sank in the course of its voyage. It was alleged that when the lighterage contract was made, it was agreed that the Chesapeake company should insure all goods while on its lighters up to the sum of $6,000, "provided there was no prior insurance." As a matter of fact the Federal Insurance Company had a policy in force covering the company which sold the goods to the libelant, "on account of whom it may concern," and it concerned the libelant apparently as holder of bills of lading for the merchandise under consideration at the time it was put aboard the barge.

This insurance covered the goods from time of shipment until delivery at destination, and specifically included "all risks of lighterage;" but such general assumption was limited by the following exceptive provision:

"Warranted by the assured free from any liability for merchandise in the possession of any carrier or other bailee, who may be liable for any loss or damage thereto, and for merchandise shipped under a bill of lading containing a stipulation that the carrier may have the benefit of any insurance granted thereon, and that any insurance granted herein shall not cover where any carrier or other bailee has insurance (whether prior or subsequent in date to this policy) which would attach if this policy had not been issued."

At the time when the Chesapeake company agreed to carry the merchandise in question it had a policy in the Fireman's Fund which by its terms covered "merchandise and property on which the insured have agreed with the shippers to provide insurance, also their legal liability in cases where they have not agreed to provide insurance." And this policy, again, carried the following: "Warranted by the assured that any insurance granted herein shall not cover where the assured or any carrier or other bailee has insurance which would attach if this policy had not been issued."

When the goods at question were lost, the libelant received from the Federal Insurance Company what would have been its loss under that company's policy, but only "as a loan, and repayable only to the extent of any net recovery it may make from any carrier, bailee or others on said merchandise." The receipt for this loan contained the usual agreement on the part of the libelant to prosecute suits as required by the Federal; hence the suit against the Chesapeake company, the contention being that the policy with the Fireman's Fund made the latter liable to the libelant.

The finding of the trial court was for the libelant as against the Fireman's Fund only, but dismissed the libel as against the Chesapeake company. Whereupon the Fireman's Fund appealed. The Circuit Court of Appeals reversed the decree of the lower court, without costs, and remanded the cause, with directions to dismiss the libel, without costs. The court held that the cargo owner could not recover on such a policy for loss of cargo as "the assured," where it had other insurance, nor through liability of the ship owner where the latter was not charged with any fault—as was the case in this instance.

Standard Marine Policy Needed

CONSENSUS of opinion is slowly crystallizing around the idea of devising a standard marine insurance policy to cover all nations. It has many supporters in America, and is being actively urged in various parts of the United Kingdom. Not long ago a Liverpool newspaper approached a number of prominent marine underwriters for an expression of opinion on the plan, and they declared that among other advantages that would follow a universal adoption of such a proposition would be the doing away with a great amount of expensive and unnecessary litigation. This would especially be true were such a policy made to apply to hulls as well as cargo. One of the difficulties appears to be as to the form of policy. It has been suggested that the only way to arrive at a satisfactory result is to have a general policy for all kinds of cargoes and all kinds of hulls for all countries of the world. Two separate policies, one for hulls and one for cargoes, would entail dissatisfaction. Says one authority: "The modifications which would be absolutely necessary to suit different classes of vessels, different forms of goods, and the many different ideas of shippers as to how much they are willing to pay for the kind of insurance they want, would lead to chaos, and in all probability involve just as much litigation as the present system." The suggestion now is to have a round-table discussion between representatives of the principal countries.

Warehouse to Warehouse

SVEND ANDERSEN, general manager of a prominent Danish insurance company, has some interesting views on the joint warehouse to warehouse clause, and he expressed them frankly in an address he delivered before the recent Second Northern Marine Insurance Congress, held at Copenhagen. His conclusions, summarized, are as follows:

1. The clause must not act as a new extension of the risk, only as an extension of the ordinary conditions of the policy.

2. Fundamentally, the clause is only valid for the ordinary course of transit.

3. The underwriter should see that his risk is limited to a certain number of days after the unloading of the goods, irrespective of whether the goods within that period reach the warehouse.

4. The underwriter should never undertake to insure the

goods after the arrival at the consignee's warehouse, and should claim all losses notified immediately at the expiration of the risk.

5. The underwriter should, in a reasonable measure, give the insured an opportunity of being covered under deviations, against an additional premium. The insured must, however, get to know that marine insurance in essence is *uberrimæ fidei.*

6. The underwriter should use a "proof" clause for composite transports to ensure that he is not to pay for losses sustained under the preceding part of the transport, when he was not on the risk.

7. The underwriter must understand clearly that the warehouse to warehouse clause is a considerable extension of the risk, and consequently claims a big increase in the premium.

New Rivet Gun Speeds Up Rivet Passing

THE need for speed and safety in passing rivets in the shipyard led to the development by the Pennsylvania Flexible Metallic Tubing Company, Philadelphia, Pa., of a machine known as the Penflex rivet gun which is intended to deliver hot rivets from the forge to any part of the ship through a special flexible tubing. The gun comprises four heavily built parts—a compressed air tank, a head mounted on the tank into which the hot rivets are dropped, a metal delivery tubing and a receiver at the end of this tubing. The completely assembled device is shown in the illustration.

In use the gun and forge are located at the most convenient point for operation, and the tubing is led to the place where the rivets are to be driven. As each rivet is heated and ready to be passed it is set by the heater on a valve provided in an opening contained in the head of the gun. By its own weight the rivet opens this valve and enters the machine. Automatically the valve recloses and the rivet is sent through the tubing by the depression of a foot treadle. This latter operation releases the compressed air, which has been supplied to the tank, into the head of the machine and the impulse shoots the hot rivet through the tube to the receiver at the other end.

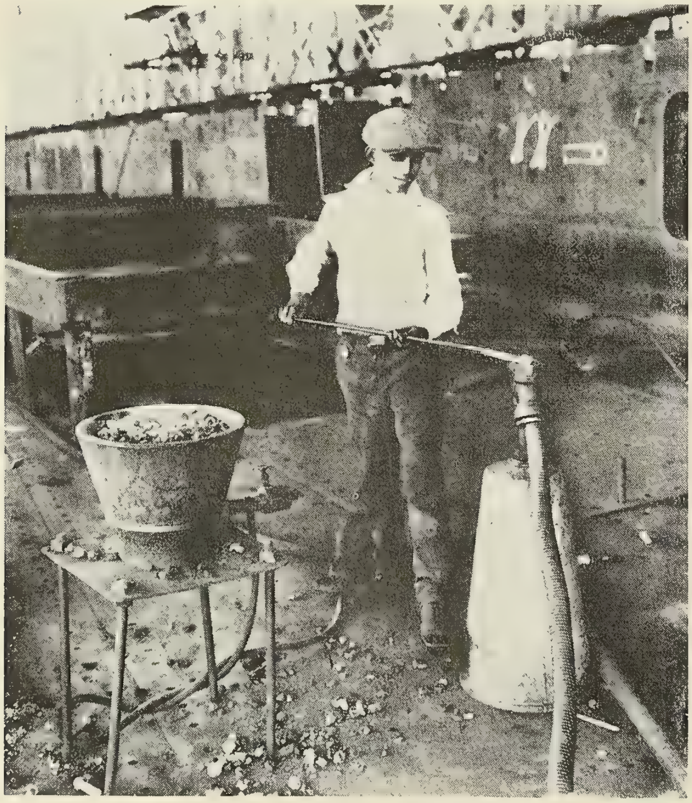


Fig. 1.—Heater Boy at New York Shipbuilding Corporation Yard Dropping Hot Rivet in Head of Penflex Rivet Gun for Delivery By Compressed Air Through Metal Tubing to Riveting Gang

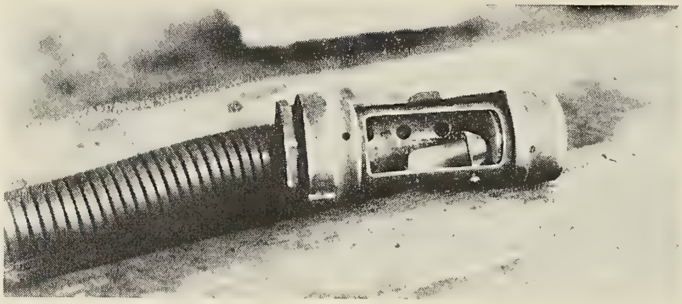

Fig. 2.—End of Metal Tubing Where Hot Rivet Is Delivered to Riveter

The standard gun has a distance capacity of 125 feet and it is stated that rivets can be delivered up or down at the rate of nearly 20 feet a second.

Corrugations are arranged in the tubing which act as a tumbling barrel and remove all hard oxide scale from the rivet so that the rivets are delivered hot free from scale.

Lehigh Car Float Launched at Baltimore

THE first of three car floats under construction at the Baltimore Dry Docks Plant, Baltimore, Md., of the Bethlehem Shipbuilding Corporation, Ltd., for the Lehigh Valley Railroad Company was launched on July 22. The float launched is the largest of the three, its principal dimensions being as follows:

Length, molded	325 feet
Breadth, molded	38 feet
Depth, molded at side	10 feet 6 inches

This float contains three tracks and has a capacity for carrying twenty loaded freight cars. It was towed from Baltimore to New York for delivery and will be used by the Lehigh Valley Railroad for conveying cars to various points in New York Harbor.

Of the two remaining floats one is 270 feet in length, 38 feet in breadth and 10 feet 6 inches in depth, while the other is 180 feet in length, 36 feet in breadth and 9 feet 6 inches in depth. All of these floats are of steel construction throughout with the exception of the deck houses which are of wood. The smallest, which is to be used in carrying refrigerator cars, has a covered platform in the center with a track on each side.

Operations of Shipping Board Vessels.—Chairman Lasker of the United States Shipping Board has recently made public the results from the operation of vessels for the month of June. The total expenses incurred in excess of income from vessel operations (including overhead, repairs, insurance and lay-up expenses) were $2,783,216.29. This result is almost as good as the result attained in May, which was the most favorable month under the present board in the operation of Shipping Board vessels. The corresponding excess of expenses over income for the month of May was $2,660,486.81, or a slight increase in the month of June of $122,729.48. The net excess of outlay over income on voyage operations for May (excluding overhead, repairs and insurance) was $376,445.84. In June, for the first time, income exceeded outlay, the excess of income over outlay amounting to $204,531.75. This improvement is due partly to the increase in passenger revenues, which for the month of June showed an excess of income over outlay (excluding overhead, repairs and insurance) of $354,630.78.

Cargo Steamer Steel Traveler, of 10,050 Tons D.W.

Designed Particularly for the Handling of Long Length Cargoes Such as Steel Rails and Structural Shapes or Lumber

THE only large ocean going steel cargo vessel designed for the carriage of general cargo, now under construction in American shipyards, is the *Steel Traveler* which will be launched at the yard of the Federal Shipbuilding Company, Kearny, N. J., about September 1. The surplus of general cargo vessels owned by the Shipping Board and now tied up in various waterways has prevented any new building except where special or very efficient types were required.

Of the other vessels designed for special freight trades now under construction, the largest are the coal and ore and the oil and ore ships of 13,500 gross tons which are being built by the Bethlehem Shipbuilding Company. Freighters for service on the Great Lakes ranging from 4,900 to 8,500 gross tons are also building at the plants of the American Shipbuilding Company, the Great Lakes Engineering Company, the Manitowoc Shipbuilding Company and the Toledo Shipbuilding Company. In addition to the above mentioned cargo ships the Bethlehem Shipbuilding Company has started work on two small freighters for the coastwise trade of the Eastern Steamship Company.

The *Steel Traveler,* although similar in design to the ten 9,600-ton deadweight freighters that have been built at the Federal Shipbuilding Company during the last three years, namely: the *Steel Worker, Steel Mariner, Steel Trader,* etc., has, nevertheless, several features incorporated in her design which will increase her efficiency over the previous vessels.

10,050-Tons Deadweight Capacity

The principal improvement is the elimination of the well aft which was made by a continuation of the bridge deck to cover the space. In this way the permissible load draft has been increased from 25 feet 10¼ inches to 27 feet and the deadweight carrying capacity from 9,380 tons to about 10,000 tons.

The vessel is a steel single screw steamship of the shelter deck type having a straight stem and an elliptical stern and it is being constructed to the highest rating of the American Bureau of Shipping, +A.1 (E). The transverse system of framing is used and there are seven watertight bulkheads, including the collision bulkhead which extends to the shelter deck and after peak bulkhead, which extends to the upper deck. There is also a longitudinal bulkhead extending from frame 104 to frame 115 dividing cargo hold No. 3 so that it may be used as a hold or ballast tank.

Accommodations

Under the steel pilot house, which contains the wheel room, chart room, wireless and battery rooms, are the captain's quarters. They consist of a stateroom, office, day room and bath which are also inclosed in a steel structure on the bridge deck. A little forward of amidships on the shelter deck are the deck officers' accommodations, including the owner's stateroom and bath. The dining saloon is located in the forward central portion of this structure with the pantry, pantry stores, dispensary stores and linen locker.

The galley is located on the same deck aft of the engine hatch in a compartment formed by a continuation of the engine casing. There are two steel houses abreast of the engine and boiler casings. The engineers are quartered in the starboard house and the petty officers in the port house. Oilers, firemen and crew are berthed in staterooms on the upper deck aft, where their mess and wash rooms are also located. The hospital, carpenter shop, store, lamp and paint rooms are situated forward on the upper deck.

Joiner Work

The pilot house and captain's quarters are sheathed with tongued and grooved cypress. Hard wood flooring is laid in the captain's rooms. The houses on the shelter deck are finished in tongued and grooved cypress with the exception of the dining saloon which is paneled in oak with white paneling overhead. The crew's quarters are also finished in tongued and grooved cypress with overhead ceiling of the same.

Brass beds are furnished for the captain, owner and chief engineer. Built-in wood berths with drawers below are fitted for the rest of the officers and wardrobes are provided in each room. The outside wood doors in the deck houses are of cypress, solid framed with solid flush panels 2½ inches in thickness.

Flooring

All rooms and passages in the officers' quarters on the shelter deck, with the exception of bathrooms, are floored with Litosilo decking 1½ inches thick. The hospital and the living and mess rooms in the crew's quarters are also floored with this material. Vitrified tiling of hexagonal shape is laid in the officers' and hospital bathroom. Linoleum ⅛-inch thick is laid in the wheel house, chart room and wireless room. Brick is used on the galley floor and both brick and tiling are laid in cement 1½ inches in thickness.

Cargo Handling

Cargo will be handled by 24 booms of long length for the particular cargo which this vessel has been designed to carry, 8 of which are 5-ton, 12 are 8-ton and 2 are 30-ton capacity. These booms are attached to 2 steel pole masts of long length and 8 tubular derrick posts. The steel derrick posts are also arranged to act as ventilators to the 'tween deck spaces and spaces below them. The five hatches are served by 8 single and 9 double geared winches so arranged that one man can handle two winches and watch his lift in the cargo holds.

Refrigerating Plant

The refrigerating machine is of the ammonia type having a capacity of 2 tons per day. The plant is required to keep the meat room at a temperature of 24 degrees and the vegetable room at 34 degrees Fahrenheit. The cold storage rooms are on the upper deck and are formed by a continuation of the engine casing. Inside the casing forming the outer walls comes a 3-inch air space, then one thickness of ⅞-inch tongued and grooved spruce, then two thicknesses of P. and B. paper, then two thicknesses of 2-inch cork, then two thicknesses of P. and B. paper, then one thickness of ⅞-inch tongued and grooved spruce, then two thicknesses of P. and B. paper, then one thickness of ⅞-inch tongued and grooved spruce, making a total of about 10 inches.

The divisional walls have first, one thickness of ⅞-inch tongued and grooved spruce, then two thicknesses of P. and B. paper, then one thickness of 2-inch cork, then one 1-inch air space, then one thickness of 2-inch cork, then two thicknesses of P. and B. paper, then one thickness of ⅞-inch tongued and grooved spruce, making a total thickness of about 7 inches.

Ventilation

There is one 12-inch ventilator fitted to the store room over the forepeak. Each hold and the corresponding 'tween deck space are served with four ventilators, which are either of cowl type, 24 inches in diameter, or tubular derrick posts fitted with mushroom tops. Two 36-inch ventilators fitted with cowls are installed at the forward end of the boiler room. These ventilators may be operated from the upper platform. The engine room is served with four 24-inch ventilators, two forward and two aft, which can be worked from the upper grating. One 15-inch ventilator with cowl is fitted at the tunnel escape trunk to ventilate the shaft alley.

Boilers

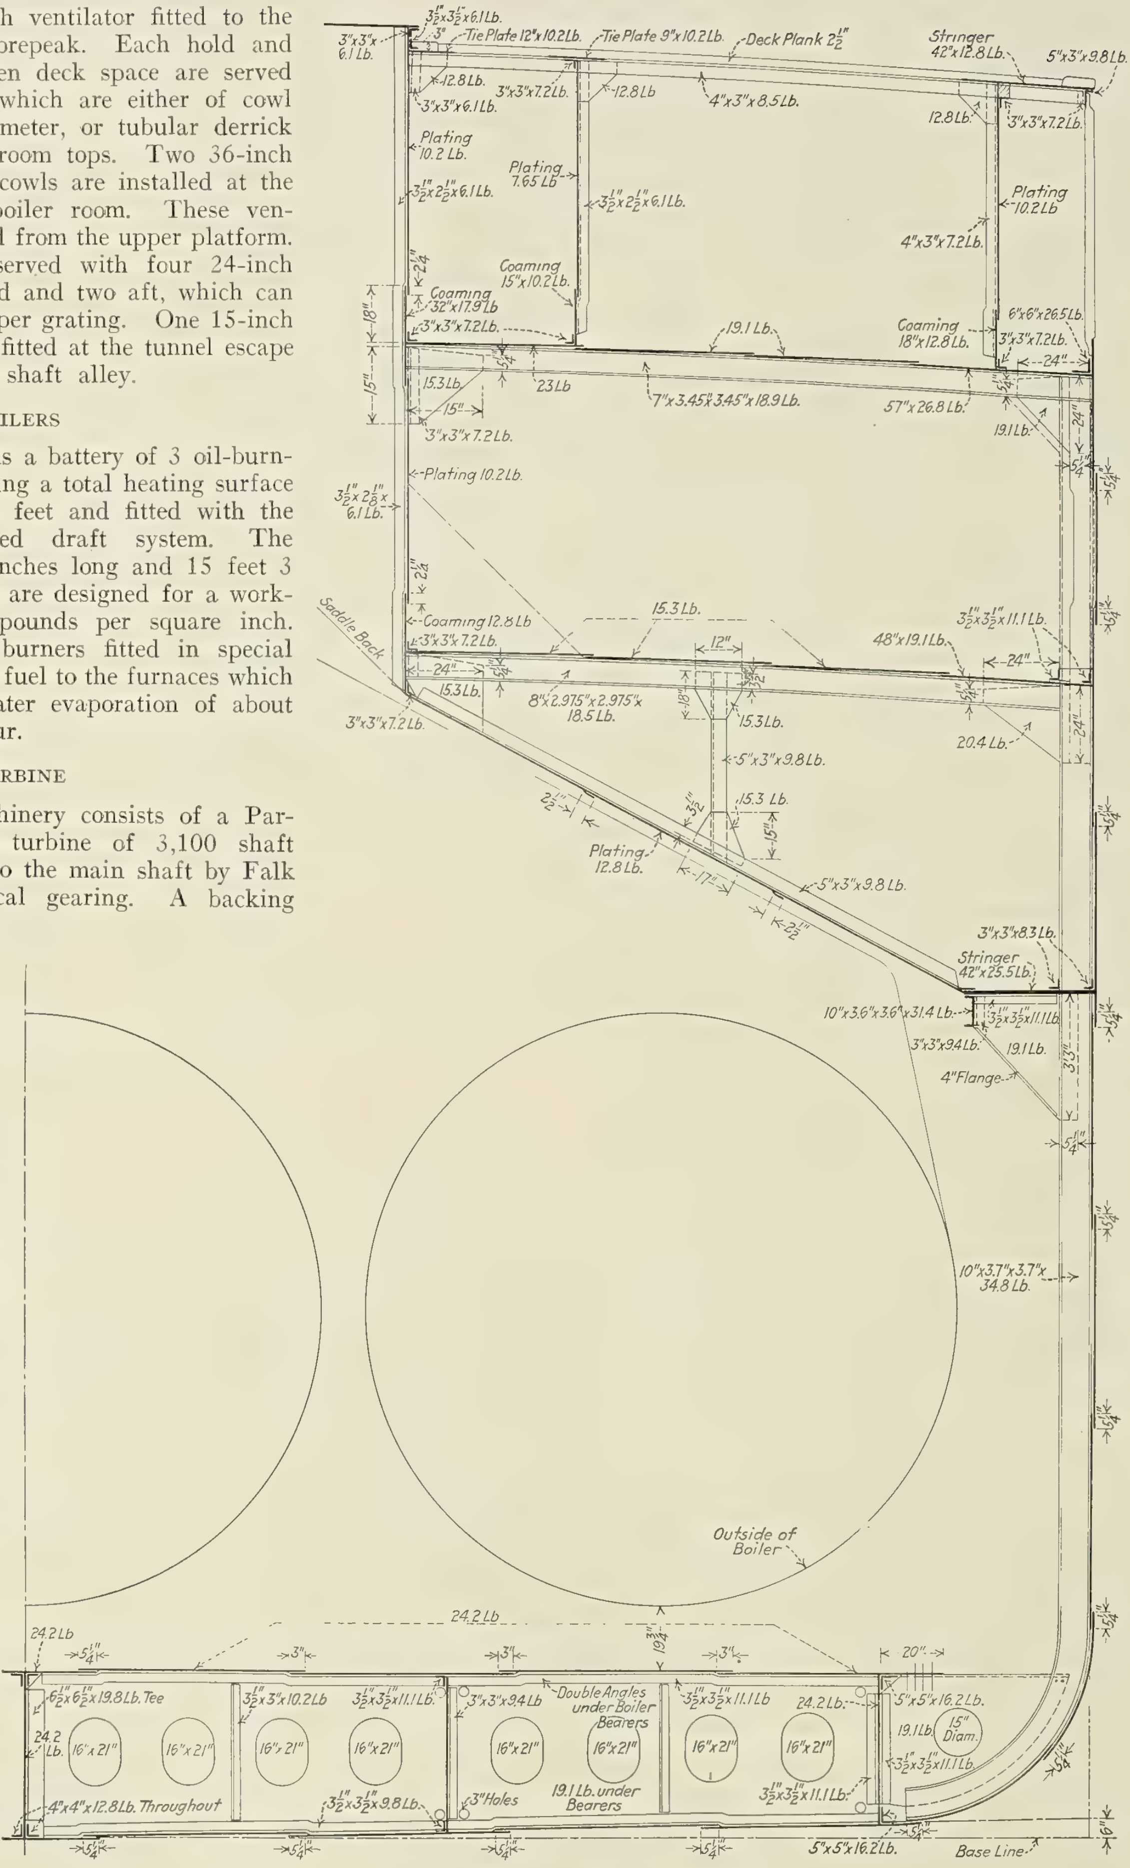
The fireroom contains a battery of 3 oil-burning Scotch boilers, having a total heating surface of about 7,836 square feet and fitted with the Howden heated forced draft system. The boilers are 11 feet 4 inches long and 15 feet 3 inches in diameter and are designed for a working pressure of 210 pounds per square inch. Todd mechanical oil burners fitted in special turret fronts supply the fuel to the furnaces which will give a normal water evaporation of about 45,000 pounds per hour.

Turbine

The propelling machinery consists of a Parsons cross compound turbine of 3,100 shaft horsepower connected to the main shaft by Falk double reduction helical gearing. A backing turbine is incorporated in the same casing as the ahead turbine which develops 50 percent of the maximum power with the same steam flow and one-half of the ahead full speed revolutions per minute.

The lubricating oil system is of the pressure type. Oil drains from the turbine and gears to a tank of about 600 gallons capacity located in the inner bottom. From there it is pumped through two Griscom-Russell Company coolers and an Elliott duplex strainer to the turbines and gears.

The auxiliary machinery, electrical equipment, propeller data and other interesting information are listed in the accompanying data sheet and further details and the arrangement of the vessel are indicated on the drawings.



Section Through Boiler Room

White Star Liner Pittsburgh Has Distinctive Features

Triple Screw Vessel of Intermediate Type Built for Moderate-Rate Service—Accommodations Comparable with Those of Express Liners

DESIGNED for the Boston-Queenstown-Liverpool service of the White Star Line, the steamship *Pittsburgh*, of 16,600 tons, is an outstanding example of the modern cabin-class ship, designed to meet a demand among persons of refined and discriminating tastes for ocean travel comforts of a superior kind at reasonable cost. She is one of the finest ships afloat for moderate-rate service.

With a length of 600 feet and a beam of 67 feet 6 inches, the *Pittsburgh* has a capacity for 600 cabin passengers, besides 1,700 in third class. Her public rooms are large and handsome. She has staterooms included in suites with private baths; an abundance of outside rooms; extensive promenade decks; a large and handsome lounge; a dining room beautifully decorated and fitted, with plenty of light, and perfectly ventilated; a smoking room comparing favorably with those of the largest ships; a gymnasium equipped with a variety of modern exercising apparatus, and a special playroom for children.

Propulsion is by Triple Screws

In construction and structural fittings, the *Pittsburgh* represents the same standard as the *Olympic*, the original *de luxe* liner of the White Star Line, which was built in the same yard as the new liner, that of Harland & Wolff, at Belfast, Ireland. The *Pittsburgh's* hull is subdivided into 14 watertight compartments and there are five completely plated decks, besides a promenade deck and boat deck.

An oil-burner, the vessel is equipped with triple screws, driven by two sets of reciprocating engines for the wing propellers, and a low pressure turbine for the center propeller.

Steam is supplied at 215 pounds per square inch working pressure by six oil fired double-ended Scotch boilers working under natural draft. The high pressure four cylinder triple expansion reciprocating engines have cylinders 28, 44, 49½ and 49½ inches diameter by 54 inches stroke. The low pressure turbine is of the Parsons reaction type.

A special feature of the machinery is the electrical installation, which includes power not only for electric lights, ventilating fans and elevators, wireless, watertight doors and various forms of equipment, but also for the steering gear and winches, which are electrically operated.

Public Rooms Are Spacious

As in most liners of recent construction, the *Pittsburgh's* chief public rooms are on the upper deck, and are lofty apartments, tastefully decorated and furnished.

A central foyer leading to the public rooms is decorated in white, the only color being supplied by doors of teak and a floor of warm-colored rubber tiles. In the wall over the landing of the staircase is a large picture with a view representing a scene in Pittsburgh. The balustrading of the staircase is painted white and is surmounted by a handrail of polished wood.

The largest public apartment is the lounge, decorated in delicate straw color, relieved by moldings and wreaths of pure white. A piano, and handsome card tables are to be found here. Palms and flower stands give an inviting atmosphere to the room, the corners of which are partly enclosed by glazed screens to form cozy retreats. There is an attractive fireplace in this room.

The writing room has a paneled wall in white with delicately modeled designs, after the style of the famous Adam Brothers. There are serviceable writing desks at various points and comfortable arm-chairs and curved seats flanking the fireplace set in a mantle of Maine marble. The furniture in this room of graceful design and pleasing color is made of birch, a characteristic American wood.

Dining and Smoking Rooms

The smoking room, in Queen Anne style, is panelled in French walnut, very simply and effectively wrought. There are ornamental stained glass windows and gilded sconces for the electric light fixtures placed in the center of various panels around the room. Chairs and seats are luxuriously upholstered in leather in a pleasing shade of blue. Ample table space is provided with groups of four chairs for card parties, if required, and isolated tables for writing purposes. The floor is covered with thick linoleum with lines of blue on a warm gray ground.

The dining room, two decks below, accommodates 400 at one sitting. It extends the full width of the ship and is fitted with tables seating two, four and six persons.

One of the distinctive apartments on the ship is the children's playroom. It is plainly paneled in oak, but enlivened by pictures illustrating the exploits of heroes and heroines of nursery legends. Toys and picture books are part of the equipment of this room.

In the gymnasium is found a chamber of old English type, with oak paneling, doors with diamond-shaped panes set in lead and equipped with iron locks, and details of finish in keeping with these features. The equipment by contrast is exceedingly modern, including apparatus for cycling, horseback riding, rowing, weight lifting, ball punching and hand ball.

Staterooms Are Attractive

One of the *Pittsburgh's* most striking features is the variety of her staterooms, and the number which look out upon the promenade deck. Located amidship are suites which comprise one or two bedrooms, sitting room and bath room. This arrangement of apartments is an innovation for ships of the cabin class.

The sitting rooms in these suites are tastefully furnished and contain a writing table, a large lounge, a pedestal table and easy chairs. Their dimensions are 10 by 11 feet, and they have two windows looking out on deck, affording abundance of light and fresh air. The connecting bedrooms are 12 feet 6 inches by 11 feet, and each contains two bedsteads, a dressing table, wardrobe, chairs and electric heaters. The bedroom has two large windows, and off the bedroom is a white tiled bathroom with an outside window.

The remainder of the staterooms on this deck are outside rooms 9 by 11 feet, many of them connecting, furnished with four berths, thus affording desirable accommodations for families. Forward of the cabin entrance on this deck are a number of two-berth outside rooms each 6 by 10 feet, which is larger than the average stateroom.

On the upper deck are situated many two, three and four-berth rooms, including a number which are "L" shaped, having an inside dimension of 6 by 10 feet, and an extension to the outside of the ship, having an overall length of 4 feet. Many of these rooms are connected with adjacent two-berth rooms, so that if necessary individual parties may be accommodated in as many as four connecting rooms, having a total capacity of ten berths. On the same deck with these staterooms are 26 bath rooms and wash rooms.

Motorship Missourian Leaving Cramp's Shipyard on July 10

Motorship Missourian Given Successful Tryout

Performance Proves That Standardization of Design and Accurate Workmanship Make It Unnecessary for a Diesel Engine to Undergo Extensive Shop Tests Before Installation in Vessel

By J. C. Shaw

On July 6 the motorship *Missourian,* which is a sister ship of the motorship *Californian* and owned by the American-Hawaiian Steamship Company, ran her builder's trial on the Delaware, returning to the yard of the Cramp Company the same day for completion before being turned over to her owners.

The owners were in a special hurry to have the vessel, which limited the time available for dock and preliminary trials, as they were desirous of putting her on the regular sailing date, which was scheduled for leaving Boston on July 15. This haste was due to a recent decision to lay up two of their steamers for repairs which were being employed on the combined coastwise and continental service.

The engine builder's preliminary trial, accordingly, consisted of a six-hour run down the Delaware and back, or a total of 12 hours.

During the preliminary trial, revolutions and cards were taken over a six-hour continuous run.

The oil-consumption trials were run in the open sea, on the way to New York, and when running between various ports for loading.

Results of Preliminary Trial

The results of a six-hour period of preliminary trial are as follows:

Starboard engine	116.65	revolutions per minute
Port engine	114.45	revolutions per minute
Mean, both engines	115.55	revolutions per minute
Starboard engine—M. I. P.	83.34	pounds per square inch
Port engine—M. I. P.	86.19	pounds per square inch
Starboard engine	2,221	indicated horsepower
Port engine	2,258	indicated horsepower
Both engines	4,479	indicated horsepower

The shallow water, in combination with the drag of the vessel due to the trim aft, had the effect of simulating loaded conditions, as it will be noted that the engines on an average developed approximately their rated power at normal revolutions, which is 4,500 indicated horsepower at 115 revolutions per minute. At the turn where the water was deeper, however, the revolutions and corresponding power were considerably above the mean values, though the control levers on the engines were not altered.

The draft on the trial, taken in fresh water, and with the inner bottom oil tanks filled with oil and the peak tanks partly filled with water, was 8 feet 1 inch forward and 17 feet 9 inches aft, or a mean of 12 feet 11 inches, corresponding to 6,579 tons displacement.

On July 10 the *Missourian* left the Cramp Company's yard for New York to dock for bottom painting, and on the 12th proceeded to Boston to commence loading, where about 700 tons of cargo were put aboard. She then went directly to Philadelphia for additional cargo, where about 3,000 tons were taken on. Afterwards she returned to New York to finish loading. From the last mentioned place she finally sailed on July 23 for the Pacific Coast.

Much fog was encountered on the way to and from Boston, when rounding the New England coast, necessitating slowing down at times, and taking the longer outside passage, via Nantucket Light. The average speed, however, on the way up to Boston, from Ambrose to Boston Light, was 12.97 knots, and on the return from Boston Light to Overfalls (or entrance to Delaware Bay) 12.89 knots.

Oil Consumption Very Consistent

The first four columns in the accompanying table show the summary of the results obtained between the different ports before leaving for the West Coast. The data in the last column were obtained by radio on the second day out, after leaving New York for the Panama Canal. From these

R. P. M. port engine	......	121.20	......	111.70	......
R. P. M. mean	115.3	121.02	121.	112.8	......
Slip, percent	6.8	.8	6.4	5.	......

figures it will be noted that the total oil consumption per indicated horsepower, main engines only, is very consistent and checks quite closely the results obtained with the motorship *Californian*, previously published.

The set of cards shown was obtained on the final run from Philadelphia to New York, when partly loaded. The only adjustment which had been made to the engines, affecting the character of the cards, since erection in the vessel, was to slightly advance the fuel cam throws on cylinders Nos. 2 and 4 of the port engine. The mean indicated pressures of the various cylinders had not yet been equalized, as this was to be carried out after leaving New York by the Cramp Company's guarantee engineer, Mr. O. Mattson, who accompanies the vessel on the first voyage.

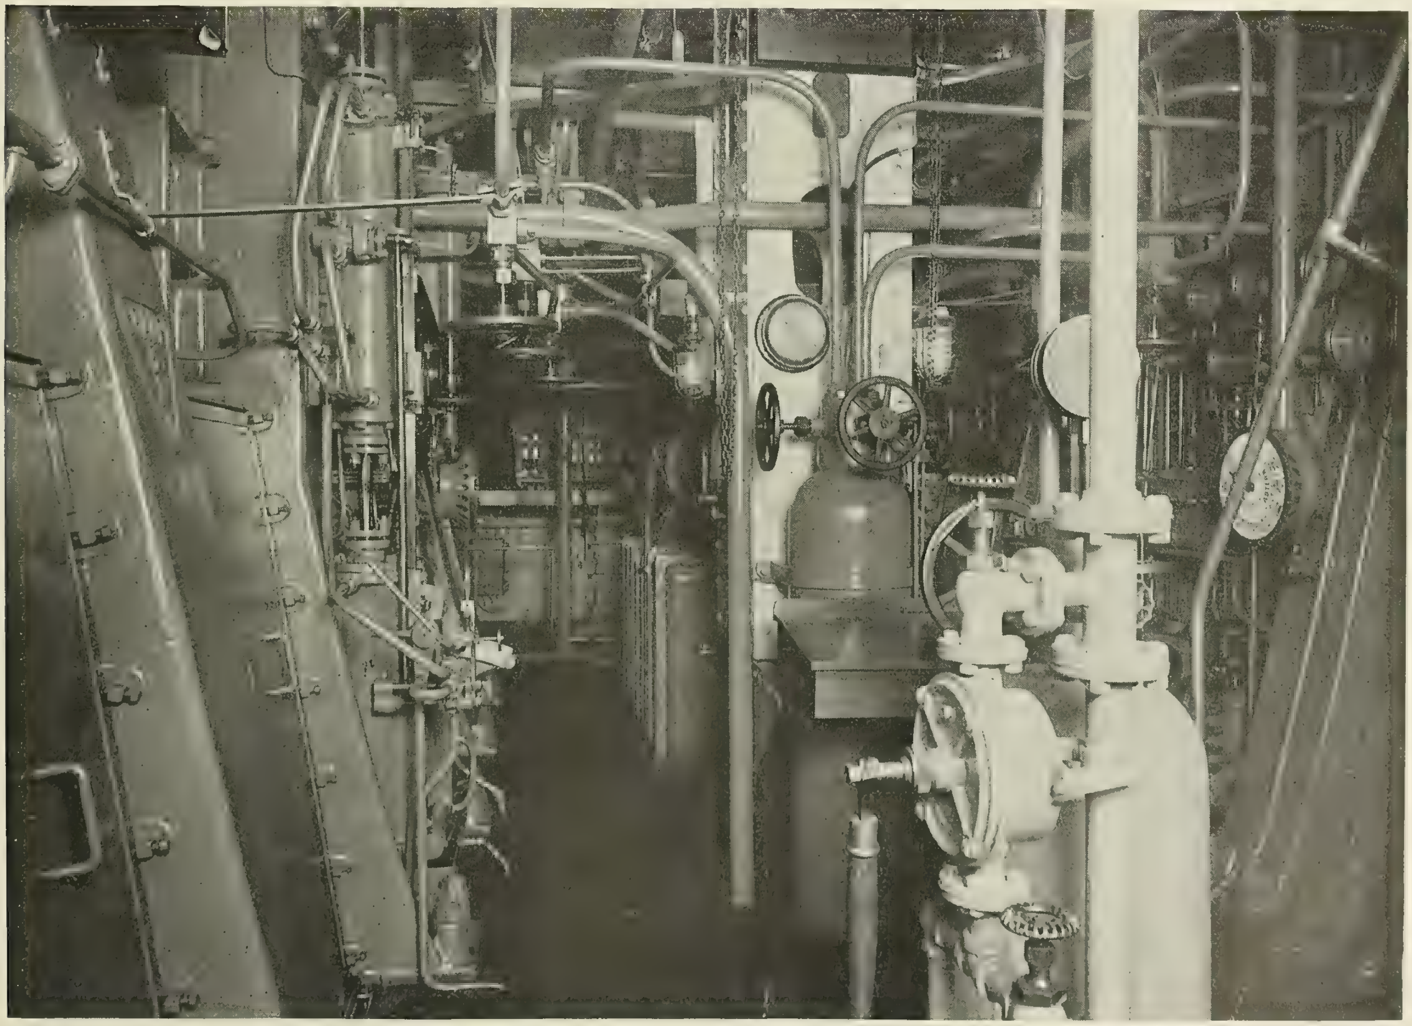
The engines were remarkably free from vibrations at all times, although the vessel was in light condition, and the revolutions of the propellers at times considerably exceeded the designed revolutions of the engines.

Carries Oil For Round Voyage

The oil, which was used on the trials, and of which sufficient is being carried for the round voyage to the Pacific Coast, returning via Panama and Europe, is the same as that furnished the motorship *Californian*. This was supplied by the Texas Company (known as Port Arthur Light Fuel), and shows the following analysis:

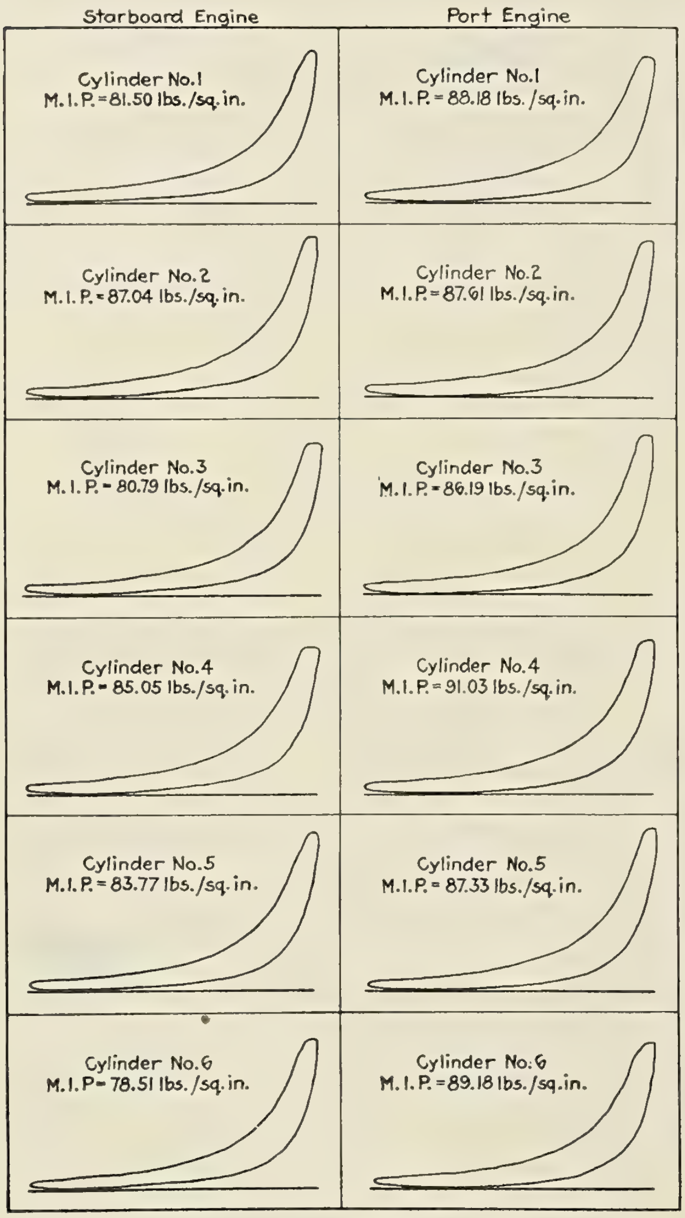
Specific gravity at 60 degrees F	.913
Be., corresponding	23.5 degrees
Flash, open cup	253 degrees F.
Fire	273 degrees F.
Viscosity. Saybolt universal	152
Sulphur—percent	.60
Hard asphalt, percent, insoluble in naphtha	1.11
British thermal units, higher heating value	19,120

The motorship *Missourian* is identical as to hull and machinery with the motorship *Californian* with the exception of



Engine Room of Motorship Missourian, Port Side, Looking Forward, Showing Operating Platform

the deck machinery. The *Californian* has fourteen winches built by the American Engineering Company, and the *Missourian* fourteen winches of similar design, but supplied by the Maine Electric Company. Both vessels, however, have two winches of the Sheppard planetary gear design located at after end of No. 2 hatch. The windlass and hydro-electric steerer are the same for either vessel, being supplied by the American Engineering Company. The chief difference in the deck machinery is that the *Missourian's* electrical equipment



Indicator Cards Show Uniform Performance of Engines

was supplied by the General Electric Company, while that of her sister ship, being the same as the motorship *William Penn,* was furnished by the Westinghouse Company. In equipping the *Missourian's* deck machinery with the General Electric apparatus it was the desire of the owners to try out the equipment of these two well-known electrical companies in a competitive way, as much of the success of the motorship as a whole depends on the reliability and efficiency of the electrical accessories, and this applies to the winches in particular.

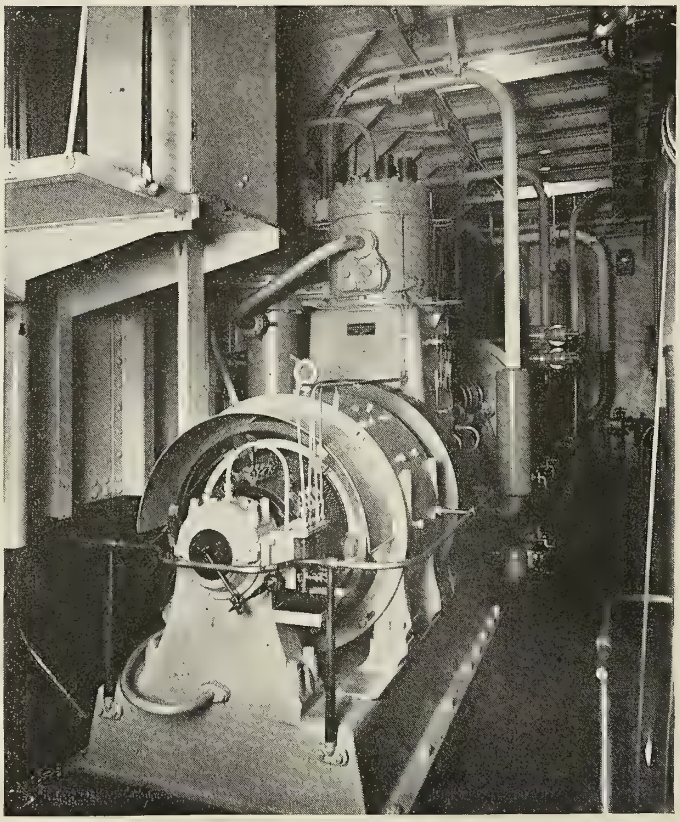
The hull of the *Missourian,* like that of the *Californian,* was built at the yard of the Merchant Shipbuilding Corporation at Chester, Pa., and towed to Cramp's yard for installation of the machinery.

View in Engine Room at Upper Grating, Port Side, Looking Forward, Showing Cross Girder and Vertical Column

No Time Lost

The port engine was turned over for the first time under power on July 1, and the starboard engine the following day. On the 4th no work was done, it being a holiday, and on the 6th the vessel carried out her 12-hour preliminary trial, as previously stated. This is an accomplishment worthy of mention and speaks well of the standardization in design and accuracy of workmanship attained by special production methods, and completely refutes the general impression that it is necessary that a Diesel engine undergo elaborate shop tests before being installed in the vessel.

The American-Hawaiian Steamship Company has the distinction among American private shipowners of having the



Starboard Side of Engine Room, Looking Aft. Auxiliary Air Compressor in the Foreground

first two all-American built motorships of large size, and comparable with the motorships abroad that are being built in considerable numbers. These vessels are being run on a route, on scheduled sailings, in conjunction and in competition with their fastest and best freight steamers. American shipowners, accordingly, should follow with keen interest the performance of these motorships in service.

The master of the motorship *Missourian* is Captain R. M. Tapley, and the chief engineer Mr. Henry Timmer, both veterans in the service of the American-Hawaiian Company.

Striking Features of Motorship Building in Europe

Development of the Long-Stroke Engine—Diesel Electric Motorships—British Designers Adopting Engines to Run on Boiler Oil

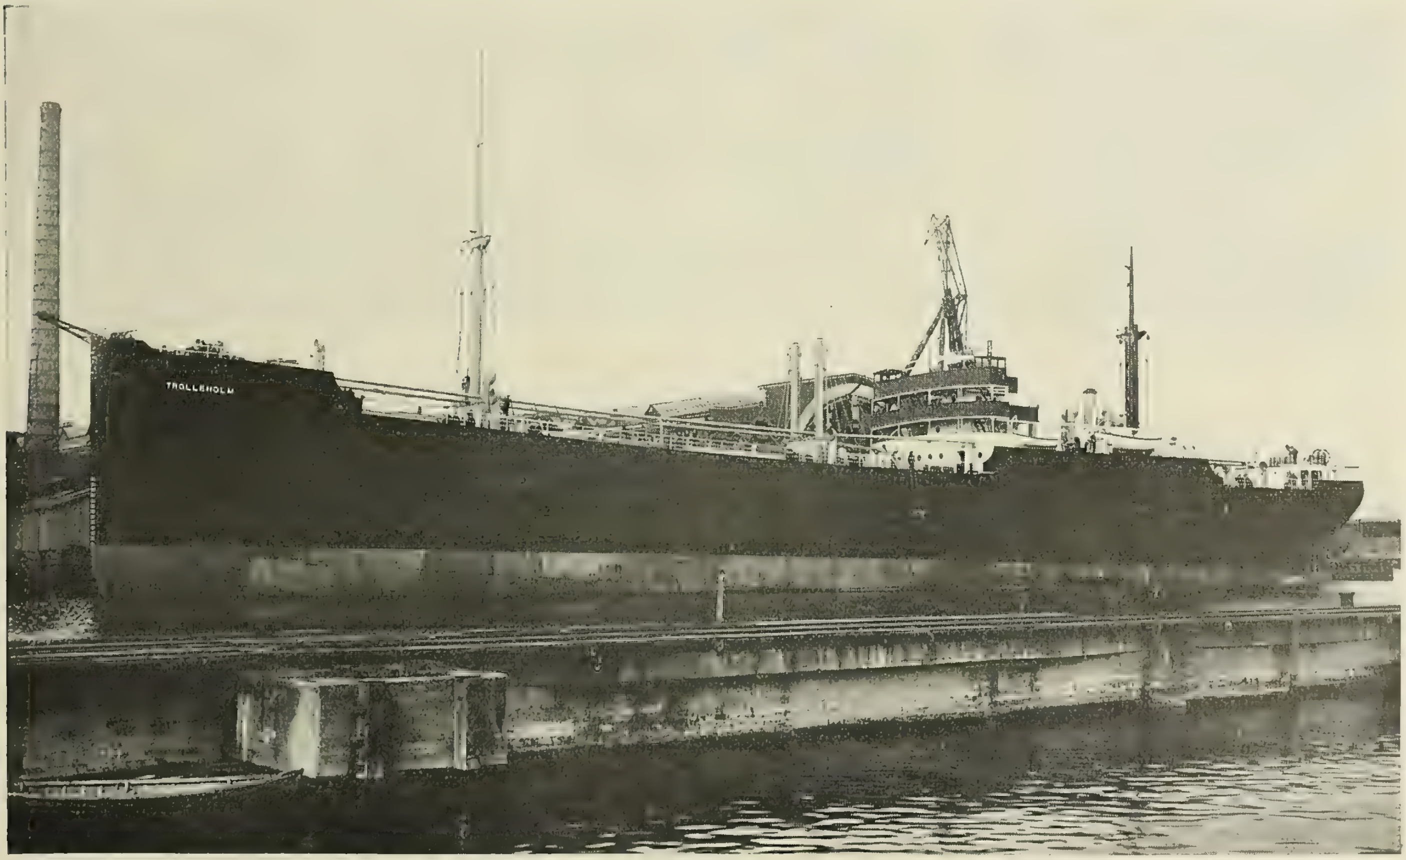
By Our Special London Correspondent

ONE of the most interesting lines of progress of marine oil engine construction in Europe during the past year, has been the development of the long-stroke motor. This is in consequence of a demand that has naturally arisen among shipowners for single screw vessels, more particularly in cases where the power of the machinery required does not exceed about 2,000 horsepower. By the adoption of this design, speeds of revolution can be kept down to a figure commensurate with those employed on single screw steamers, as the modern long-stroke Diesel engine is designed to run at about 75-90 revolutions per minute.

In spite of the depressing shipping situation, quite a number of orders for oil engined vessels have recently been placed, and among these are contracts for five ships to be provided with single screw plants. A short time ago it was considered desirable to install twin engines if only from the standpoint of reliability, but no doubt the success of the Doxford engined vessels and other single screw motor craft, has caused shipowners to change their policy in certain cases.

Hence the latest motor liner for the Holt line, which has just been laid down, and which is a 10,000 ton ship, will be equipped with the largest Burmeister & Wain long-stroke engine that has yet been built. It will develop 3,000 horsepower in eight cylinders, and run at about 85 revolutions per minute. The stroke bore ratio will be rather more than 2 instead of 1.5 to 1.6, and other new features in design will include the extension of the long vertical steel bolts to the tops of the cylinder covers, whereas in the normal arrangement, they only reach to the top of the cylinder barrels.

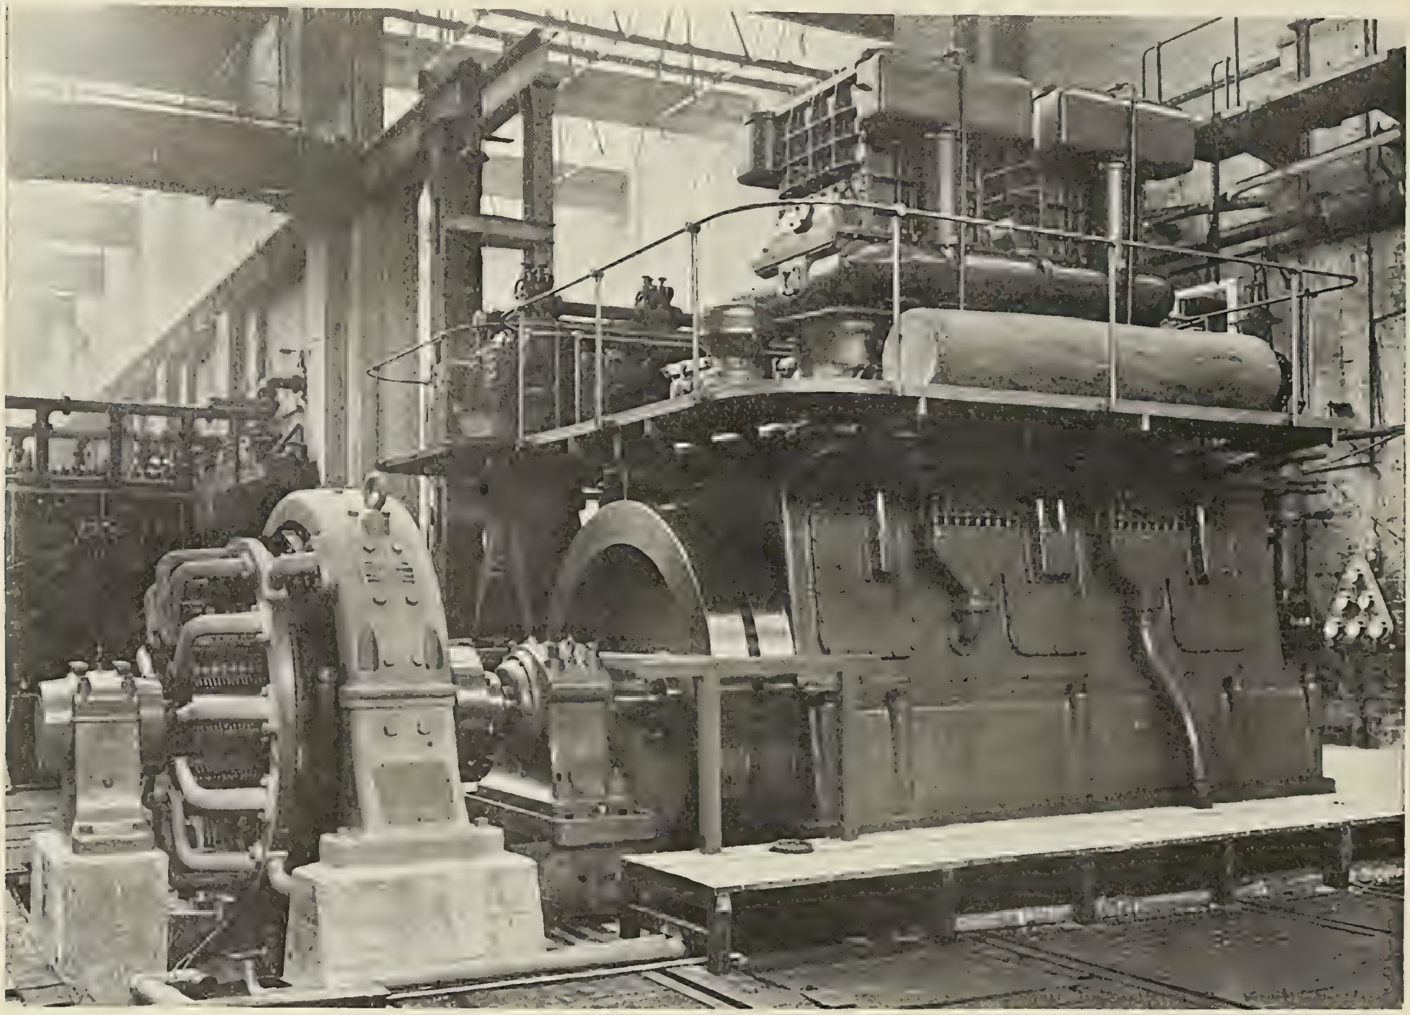
Another alteration lies in the adoption of a means for varying the lift of the fuel valve, according to the speed of rotation, this usually being considered unnecessary with short-stroke Burmeister & Wain engines. It will be remembered that the William Cramp & Sons' Ship and Engine Building Company is also constructing one of these long-stroke Diesel motors with the object of converting an existing steamer; and an order for three further ships has recently been placed on the Clyde for which Messrs. J. G. Kincaid and Company will supply the machinery.



The New 7,500-Ton Motorship Trolleholm

Diesel Electric Motorships

As a marine engineering proposition, the propulsion of ships on the Diesel electric system is of unusual interest. Messrs. Cammell Laird and Company, which has developed the Camellaird Fullagar engine with opposed pistons, has taken up the problem of the Diesel electric drive, and has received an order for three ships embodying this system, for the United Fruit Company. There will be no fewer than four generating sets installed in the engine-room, developing a total of 3,400 brake horsepower and the electric motors will drive the propellers direct at a relatively low speed. The engines will not differ from the Camellaird Fullagar marine design which is now so well-known, except in certain details, but they will operate at much higher speeds, probably at about 250 revolutions per minute.



The Camellaird-Fullagar Diesel Generating Set. Four Units are To be Installed in Motorships for the United Fruit Company

One of the licensees of Messrs. Cammell Laird and Company, the English Electric Company, has already developed a stationary Camellaird Fullagar engine, of which an illustration is published, and the sets installed in the new ships will not show any marked variation from this construction, although they will be of somewhat higher power. A specially sensitive governor is provided, and the somewhat peculiar features of the Camellaird Fullagar marine engine will be embodied, including a square section scavenging pump, arranged at the top of each cylinder. The absence of reversing mechanism will of course render the design very simple and it is believed that in spite of the electrical gear, a considerable reduction of weight will be effected as compared with an ordinary marine equipment.

The reductions in the prices of liquid fuel at British ports, which have recently been announced, will undoubtedly give a fillip to the motorship industry. Diesel oil is quoted at £4 per ton at British ports, and boiler fuel at £3 per ton, and it is evident that, especially for those motorships equipped with machinery which can operate on the heavier and cheaper oils, the possibilities of effective competition by steamers are remote. Hence, it is not surprising that builders of marine oil engines are making every endeavor to design their motors so that they will operate satisfactorily and continuously on the low grade fuel.

The performance of one of the Doxford engined ships, the *Dominion Miller,* is interesting in this connection. On a long run at a speed of 11½ knots, boiler oil was used exclusively, the amount consumed being 10½ tons daily for a vessel with a deadweight of between 9,000 and 10,000 tons. No special precautions appear to have been taken except that heating coils are provided to render the oil sufficiently liquid to flow under all conditions. Obviously if one type of engine proves that it will burn boiler oil with complete satisfaction, makers of other designs will have to guarantee equal performance for their motors, since the saving in the fuel bill at present prices amounts to quite 30 percent.

The Motorship "Trolleholm"

Motorship building in Scandinavia seems to be boiling itself down to the development of a limited number of standard types, since both shipowners and engine builders are desirous of obtaining the advantages which can be derived by repetition construction in marine oil engines. The latest example of one of these classes of standard ship is the *Trolleholm* built for the Swedish American Mexico Line and engined by Burmeister & Wain.

She has a deadweight of about 7,500 tons, is 367 feet in length between perpendiculars with a molded breadth of 51 feet 3 inches and a draft of 24 feet 8½ inches. Two engines are installed, totalling 2,100 indicated horsepower, the speed of rotation being unusually high, namely 150 revolutions per minute. This class of ship appears to have given very satisfactory service, since when fully laden and averaging 10½ knots, the total consumption does not exceed 8 tons for all purposes. The usual electrical equipment is provided, the donkey boiler being only used for heating purposes. Ten three-ton winches are fitted, and the steering gear and engine-room auxiliaries are driven by electric motors.

Stability of Ships at Large Angles of Inclination*

Explanation of Matrosov's Stability Calculations—Application to Lumber Carrying Steamer—By Tabulation, Work Is Reduced to Simple Arithmetic

By P. Jankov

IT is generally considered that stability calculations for "small angles of inclination" hold good for angles up to 10 degrees, but when a ship is inclined to such an angle that the side of the weather deck becomes immersed, the volumes of the "in" and "out" wedges become different,

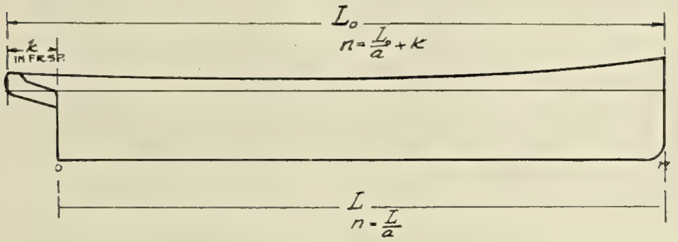


Fig. 1

and the displacement becomes greater or less depending on whether the "in" or the "out" wedge, respectively, becomes greater and the other wedge less. The change in the volume of the submerged hull is accompanied by a change in the location of the center of buoyancy C_0. Thus the

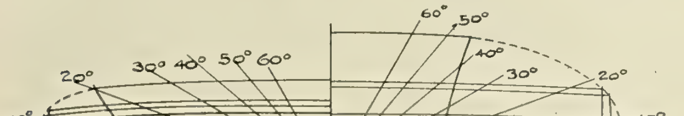

Fig. 2

distance between C_0 and the center of gravity of the ship G_0 is also changed. The change in the area of the load water plane affects the position of the metacenter M_0 in one direction or the other. In brief, the relative locations of all the three significant points change when the angle of inclination becomes great.

To estimate the stability of the ship at greater angles of inclination according to the methods ordinarily in use, it is necessary to perform numerous long and laborious calculations, and this work is further increased if it is desired to find the stability for several different conditions of loading. But great saving of time is effected by using the method described below, the development of which is credited to A. Matrosov, a Russian naval architect, and which is said to have been in use in all the larger Russian shipyards. The procedure is exceedingly simple and, if the work is

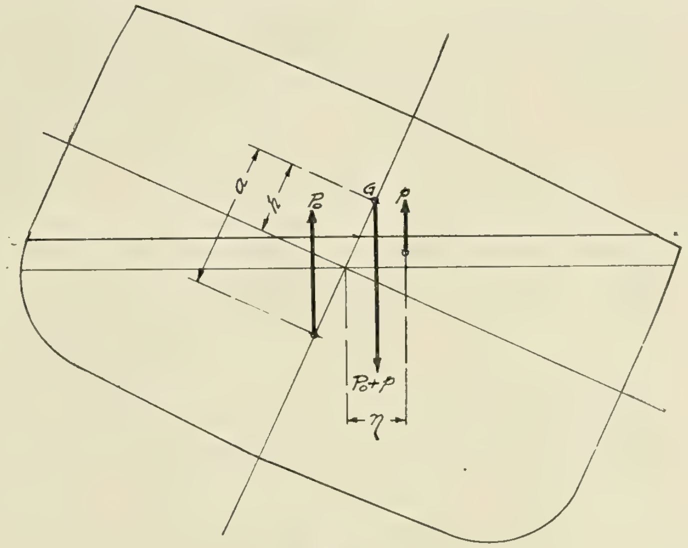

Fig. 3

tabulated as here indicated, it becomes reduced to simple arithmetic.

Matrosov's method for calculating stability is especially valuable for ships intended to carry lumber cargoes, since the stability calculations for the normal load waterline will not apply when the ship is loaded to the smaller freeboard permissible in many trades in lumber, especially when a deckload is carried. For this reason Matrosov's method is here explained using as an example a lumber-carrying steamer of 3,323 tons displacement at 18 feet 6 inches draft, the length being 240 feet. There are 128 frame spaces of 1.875 feet each.

MATROSOV'S METHOD

The center of gravity of the ship G_0 is found by trial, after which the lever arms for different angles of inclination may readily be calculated by means of Table VII, and the static stability diagram may be drawn.

For these calculations it is necessary to have a line drawing of the ship and to know the displacement P_0 or the draft

H_o. Before column III, Table I, is filled in, which column gives the locations of Tchebycheff's sections, it is necessary carefully to choose the length of the ship (see Fig. 1), which is given by the number of frames and distance between frames ($n = L_o/a$, where a is the length of the frame space).* This is necessary because the length of L_o is not necessarily equal to the length between perpendiculars, so that a correction k may have to be made (e. g., for a ship with a long cruiser stern).

The length decided on is multiplied by the coefficients given in Column II, which are the abscissæ corresponding to Tchebycheff's sections, expressed in thousandths of the length of the ship, from the after perpendicular. Column IV gives these abscissæ in feet.

From the lines are worked up the sections for Tchebycheff's rule (see Fig. 2), nine half-sections to a ½-inch scale in general being satisfactory. All the sections must be closed by drawing in the line of the uppermost watertight deck. Now the four fundamental quantities are taken off the lines for each condition of loading, such as full load, ballast and other conditions, and are entered in their proper positions in the tables, namely, the displacement P_o, the height of the center of buoyancy C_o, and the length L_o at draft H_o. In case only the draft is known, the displacement P_o and the position of the center of buoyancy may be found as indicated in Table A, where the summation is done by means of Simpson's and Tchebycheff's rules. From this table the displacement curve may be drawn up in the ordinary manner.

On the body plan giving Tchebycheff's sections, waterlines for inclinations for every tenth degree up to 60 degrees (continuation of this work up to 90 degrees is of no practical value) are now drawn through the intersection of the normal load waterline and the center line, which brings us to Table II. This table is divided in an upper and a lower part, the upper part containing the ordinates of the water planes for the various inclinations, the squares and cubes of the ordinates and the sums of the vertical columns for the immersing side of the ship; while the lower part of the table gives the corresponding values for the emerging side. The ordinates are scaled off the body plan (Fig. 2), in general, sufficient accuracy is obtained, if the ordinates are read to one decimal place, their squares entered in whole numbers only and their cubes to the nearest ten.

In connection with Table III attention should be called to the fact that columns IV, IX and X are used for calculating the principal moment M, while the other columns serve for estimating relatively minor moments n, the computing of which does not require so high a degree of accuracy. Columns II and IV contain, respectively, the sums of Σy and Σy^3 from the upper and lower parts of Table II, and column III gives the difference $\Sigma y_1^2 - \Sigma y_2^2$ from Table II. Column V contains the products of the values in column II multiplied by $\lambda = L_o/a$, giving areas of the water planes.

Of course, the water plane areas as found do not check with the actual values, since the water planes do not have a common point of intersection. On account of the difference between the volumes of the emerging and immersing wedges, the actual water planes will lie above or below and be greater or less than those drawn; but the error in the areas of the water planes may be disregarded without undue sacrifice of accuracy. Column VI gives the static moments of the water planes with reference to an axis that coincides with the intersection of the load waterline and the longitudinal

*This is based on uniform frame spacing. Where frame spacing is not uniform, the method should be modified to suit conditions.—Translator.

DISPLACEMENT P_0=3323 TONS; CORRESP. DRAFT-H_0=18'-6"; CR. OF BUOYANCY ABOVE KEEL = C_0 = 10'.03;

C.G. ABOVE KEEL = g_0 = 13'.5; LENGTH OF SHIP = L_0 = 240'-0"; $\lambda = \frac{L_0}{9} = 26'.67$; $\frac{1}{2}\lambda = 13.33$. $\frac{1}{3}\lambda = 8.89$;

$\phi = \frac{\pi}{18} = 0.1745$; $\frac{1}{2}\phi = 0.0873$

center plane. The figures are obtained by multiplying the values given in column III by $\frac{1}{2}\lambda = L_0/18$.

By dividing the values of column VI by the corresponding values in column V, we obtain the distance η of the center of gravity of the water plane from the above axis, the quotients being given in column VII. Column VIII contains the values of $\frac{1}{2}\lambda$ $\frac{1}{2}\phi$ $(\Sigma y_1^2 - \Sigma y_2^2)$, which gives one-half of the volumes of the emerging wedges for the various angles of inclination. The moments of inertia of the water planes of inclination, $I = 1/3\lambda$ $(\Sigma y_1^2 + \Sigma y_2^3)$ are given in column IX, and the moments of the angles of inclination, or the products $I\phi$, are given in column X.

The principal moment M is found as shown in Table IV. The second column is taken from column X, Table III, the values are multiplied by the cosines of the angles of inclination (given in the third line from the bottom), and the products are entered as indicated. When all the triangles have been filled, the products are added diagonally. These calculations may be indicated thus:

In the third column, $\frac{1}{2}m_{60\text{ deg.}}$, $\frac{1}{2}m_{50\text{ deg.}}$, $\frac{1}{2}m_{40\text{ deg.}}$ ..... $\frac{1}{2}m_{0\text{ deg.}}$ In the second column, $.985m_{50\text{ deg.}}$, $.985m_{40\text{ deg.}}$ ....$.985m_{0\text{ deg.}}$, etc. And the summation, $M_{60\text{ deg.}} = \frac{1}{2}m_{60\text{ deg.}} + .985_{50\text{ deg.}} \ldots + .500m_{0\text{ deg.}}$, etc., which sums are entered in the last line of the table. These sums are the resulting righting moments at the various degrees of inclination.

Table V is used for finding the correction moment n due to the difference in the volumes of the emerged and immersed wedges. In line III are entered the figures from column VIII, Table III, and in line II the same figures are entered but here they are transposed so that the value given for any stated angle of inclination is entered under the next higher angle. Line IV, which gives the sums from the previous lines, thus indicates the increases in displacement for the various angles of inclination. In line V are entered the values for η from column VII, Table III, which are multiplied into the figures of the previous line, giving the desired correction n.

Table VI is used for assembly purposes. In the upper line are entered the values for P_0, G_0 and for $a_0 = g_0 - c_0$ (i. e., the distance between the center of gravity and the center of buoyancy). The total righting moment is $M - n - P_0a_0\sin\phi$, the value of which may be found for every tenth degree by means of this table.

It seems sufficient to add that in column I are entered the differences between the values for M and n for corresponding angles of inclination. In column II the same differences are given expressed in foot-tons, which values are obtained by dividing the figures in column I by 35. Column III gives the correction for the location of the center of gravity of the ship, which is expressed by $P_0a_0\sin\phi$. Column IV contains the differences between columns II and III, so that the figures in this column are the total righting moments. By dividing these moments by P_0 we obtain the corresponding lever arms, which are entered in column V, Table VI.

In order to obtain the corrections for loadings other than normal, Tables VII and VIII are made out. The total righting moment effective when the ship is loaded more deeply than to the normal load waterline is given by $M - n - P_0a\sin\phi + p(\eta - h\sin\phi)$, in which the last member is the correction for the excess load. In the formula p is the excess load in tons, η the figures from Column VII, Table III, h the distance of the center of gravity of the overloaded ship from the normal load waterline. The expression M-n is constant and may be figured once and for all, while the other members of the formula vary with the different locations of the

Twin Vane-Wheel Propulsion of Ships

Model Experiments and Full-Size Ship Trials Show High Propulsive Efficiency Possible with Vane-Wheel Drive

PROPULSION by means of a screw, or screws, partially immersed has been experimented with at various times with small success, but recent experimental investigations with models by William Denny and Brothers, Ltd., Dumbarton, Scotland, have revealed the conditions that must be fulfilled in order to secure the advantages of this form of propulsion, and the model results have been confirmed by actual tests on a full-sized ship.

Partly immersed propelling wheels, such as side or stern paddles, are usually associated with vessels of such limited draft, in relation to speed and power, as to prohibit the application of screw propellers except at a great sacrifice of propulsive efficiency. It appears from the recent Denny experimental investigations with models, confirmed by a trial of a full-sized ship, that vane-wheels can not only advantageously replace other means of propulsion in such vessels, but may also be profitably applied to numerous cases where the draft is not so restricted, the limiting considerations being apparently, relative staunchness, or freedom from possible damage, if the vessel is to ply in rough seas. The suitability, or otherwise, of vane-wheels for rough seas has, however, yet to be proved and determined.

Vane-wheels, as manufactured by Messrs. Denny and Brothers, are partly immersed wheels having their axes above water and substantially in the line of advance. They are fitted with propelling vanes over the immersible circumferential portion, the vanes having a pitch so that when the wheels are rotated they exert a forward thrust on the vessel.

In order to avoid any undesired steering effect, it is necessary to have two vane-wheels of identical dimensions, and symmetrically placed in relation to the hull of the ship. The pitch of the vanes of one wheel is right-handed and of the other left-handed. They are rotated in opposite directions—preferably outward on top—so that the transverse thrust of each vane is balanced by that of the other when they are driven at the same revolutions per minute; also the steering effect of each forward thrust moment is equal and opposite.

The dimensions, pitch and area of the vanes must be designed to suit the speed, revolutions per minute and power. The vane-wheels may be placed side by side abaft the stern of the ship, or they may be placed one on each side of the ship at any point forward of the stern.

The advantages of the twin vane-wheel method of propulsion are as follows:

A. High propulsive efficiency in relation to all other known methods of propulsion.
B. Great maneuvering powers.
C. Effective variation of water acted upon with variation of draft, and therefore of variation of the thrust required.
D. Higher revolutions per minute than either side paddle wheels or stern paddle wheels, and therefore less weight of machinery.
E. With vane-wheels abaft the stern of the ship the overall width is less than that with side paddle wheel method; there is also less overall length of ship and wheels than in the stern paddle wheel method.
F. The wheels are stronger and lighter than either side paddle wheels or stern paddle wheels.

With regard to the advantage *A* it appears that vane-wheels are so very efficient as to warrant their adoption in many cases of vessels of deep draft. Without referring to the results of numerous experiments with models of vane-wheels applied to models of ships, it will be sufficient for present purposes to give the actual results obtained from measured mile trials of a twin-screw ship, which was first tried with her twin screws, and afterwards with vane-wheels

Denny Brothers' Experimental Vessel Fitted With Vane-Wheels for Its Propulsion

Stern View of Vane-Wheel Propelled Vessel Under Way, Showing Wake

driven by leather belting from the main engines (a temporary arrangement). The particulars of the vessel, and results obtained, are as follows:

Length	100 feet
Breadth	23.5 feet
Draft, forward	4 feet 5½ inches
Draft, aft	4 feet 8 inches
Draft, mean	4 feet 6¾ inches
Displacement	186 tons
Speed	9 knots

	Screw Propellers	Vane Wheels
Diameter	4 feet	11 feet
Pitch	5 feet 8 inches	16 feet
Number of blades	3	3
Total disk area	25.14 square feet	....
Total projected area	10.2 square feet	....
Immersion of tips in still water	3 7/16 inches	....
Revolutions per minute	226	66
Total sectional area of water acted upon when at full speed	....	59.26 square feet
Effective horsepower of naked hull	77.5	77.5
Shaft horsepower	197	116

It will be seen that the vane-wheels gave the same speed as the twin screws with 41 percent less shaft horsepower.

Experimental Vessel Driven by Twin Vane-Wheels at Nine Knots

This was confirmed by the measured difference in oil consumption allowing for the loss due to the belt drive.

It will also be seen that the propulsive efficiency of the twin screws was rather low, though the resistance of the shaft brackets and projections (in this case amounting to 12 percent of the effective horsepower of the naked hull), together with the effect of the small immersion of the tips of the propellers, would probably not permit of a much higher efficiency being obtained.

In evolving a new design for a vane-wheel vessel several alternatives are available. If the speed is fixed, then the vane-wheels will require considerably less power than twin screws for the same dimensions and form of ship and this will permit of either increased deadweight, or, by the adoption of finer lines for the vessel, a still further reduction of power for the same speed. If it be preferred to obtain a higher speed than twin screws will give for the same dimensions and form, then the increase of speed depends on the relation of increase of power to increase of speed, but it will, in any case, be a considerable amount.

Advantage *B* must be seen to be fully appreciated, but a vane-wheel vessel can be made to turn very rapidly about its own axis without advancing.

Advantage *C* is somewhat unique, for, although side paddle wheels and stern paddle wheels seem to possess the same advantage, yet for understandable reasons it is well known that their propulsive efficiencies become considerably reduced with both over immersion and under immersion, i.e., the design does not permit of much variation of draft of ship. In the case of vane-wheels every portion of the immersed vanes is applied effectively at all drafts. The vane-wheels permit of considerable variation of immersion, so that at the deeper drafts they have the advantage of acting efficiently on a greater sectional area of water, and thus the revolutions per minute and slip, for the same speed, are not so variable in terms of draft variation as is the case with the other available methods of propulsion.

At the lighter drafts of a vessel which is run at considerable variations of draft the percentage reduction in the sectional area of the water acted upon is greater than the percentage reduction of thrust, so that, if the pitch of the vane-wheels be uniform, the revolutions per minute and slip will be greater than for the deeper drafts.

It is proposed to make experimental investigation to ascertain if further advantage can be secured by gradually increasing the pitch of the vanes towards the extreme diameter, with a view to securing even less variation of revolutions per minute with varying draft and the same speed.

An explanation of the causes of the high propulsive efficiency of the vane-wheels may be found in the following facts:

The hubs of the vane-wheels are out of the water and therefore involve no extra resistance as in the case of ordinary screw propellers. Vane-wheels do not require any immersed supports as in the case of twin screws, e.g., bosses or brackets. Every portion of the immersed vane is acting efficiently during its passage through the water, being superior to paddle floats in that respect. Vane-wheels can be, and are, more favorably placed in relation to the flow of water around the hull than is the case with ordinary screw propellers or with stern paddle wheels.

Pneumatic Tools

TWO new developments in pneumatic tools made by the King Pneumatic Tool Company, Chicago, are a sleeve-type valve for riveting hammers and a "Progressive" lock for both chipping and riveting hammers which prevents the handles from coming loose on the cylinders.

The King sleeve valve for riveting hammers is designed to eliminate valve breakage and reduce the necessity of oversizing valves to a minimum. In the King riveting hammer valve the hard and fast hitting qualities of the hollow-valve type riveting hammer are maintained and the question of valve breakage is claimed to be solved. Formerly a riveting hammer piston in hollow-valve type hammers came in direct contact with the valve; the piston and the valve moved in opposite directions and the piston came in direct contact with the valve 1,050 to 1,720 times per minute, according to the length of stroke of the hammer. This constant contact between piston and valve resulted in fatigue of the metal in the valve itself, with resulting valve breakage.

In the King sleeve-type valve the sleeve is interposed between the valve and the piston, making any contract between the two impossible. At the same time the sleeve provides a continuous bearing surface for the piston. An added advantage of the sleeve-type valve is that the sleeve serves as a guide to the valve in its travel, thus reducing the lateral wear to a minimum. This new device has been so successful in eliminating valve breakage that last year, out of 5,000 King sleeve valves placed in service, only 15 cases of breakage were reported.

King pneumatic tools are now made entirely of molybdenum steel, which has added to their strength and durability.

A Double Acting Marine Diesel Engine

Satisfactory Tests on 240 Horsepower Unit Causes Rapid Construction of Three-Cylinder, Two-Cycle 2,000 Brake Horsepower Engine

THE North British Diesel Engine Works has evolved a double acting Diesel engine having three cylinders of small dimensions and working on the two-cycle principle. Thus another type of marine engine is added to the long list. The job of the marine engineer of thirty years ago, with his reciprocating steam engine, looks like a sinecure today in comparison with the study and work that must now be put in just to keep up to date with the various developments.

A long struggle for supremacy is bound to occur between the turbine with its mechanical reduction gears, the turbine with the electric drive, the Diesel engine with the direct drive, reduction gears both mechanical and electrical, single, compound, two-cycle, four-cycle and double acting, to say nothing of such variations as opposed pistons and combinations of steam and oil fuel.

Competition will be keen and for this reason the double acting oil engine offers theoretical possibilities in the reduction of weight and space and in simplicity that the development of this type of engine is bound to be watched with interest. The shipowner of course wants the type of engine that will reduce his operating costs to a minimum but above all he demands regularity and reliability of performance.

The engine illustrated by Figs. 1 and 4 was built and thoroughly tested by the North British Diesel Engine Works. It has two working cylinders of $11\frac{1}{2}$ inches bore and $14\frac{1}{2}$ inches stroke. At 250 revolutions per minute it develops 240 brake horsepower. This engine is said to be very carefully balanced and it is claimed that with a combination of anywhere from 3 to 8 cylinders a balance can be obtained that will compare with that of a four-cylinder triple or quadruple expansion steam engine.

Principle of Operation

The diagram shown in Fig. 4 illustrates the principle upon which the engine operates, although some changes and improvements have been embodied in the 2,000 brake horsepower engine that is now under construction.

The engine consists of an open ended cylinder *A*, made in two parts and flanged for bolt connections in the middle. The water jacket *B*, together with the scavenge and exhaust pipes *C*, C_1, *D*, D_1, are free to reciprocate using the top and bottom cylinder covers *E*, E_1 as guides. The cylinder covers are stationary being fitted with gas tight rings of the piston type. Each cover is fitted with a fuel and starting air valves.

Piston and Connecting Rods

The trunk type piston *F* is fitted with a gudgeon pin *G*, which projects through the axial slots *V* in the cylinder *A*. The crosshead slippers *K*, K_1 are fastened, one at each end of the gudgeon pin. Bearings *H*, H_1 are provided on the parts of the crosshead slippers which are attached to the ends of the gudgeon pin *G* to take the connecting rod top end bushes *J*, J_1. The connecting rods *L*, L_1 run between the cross-

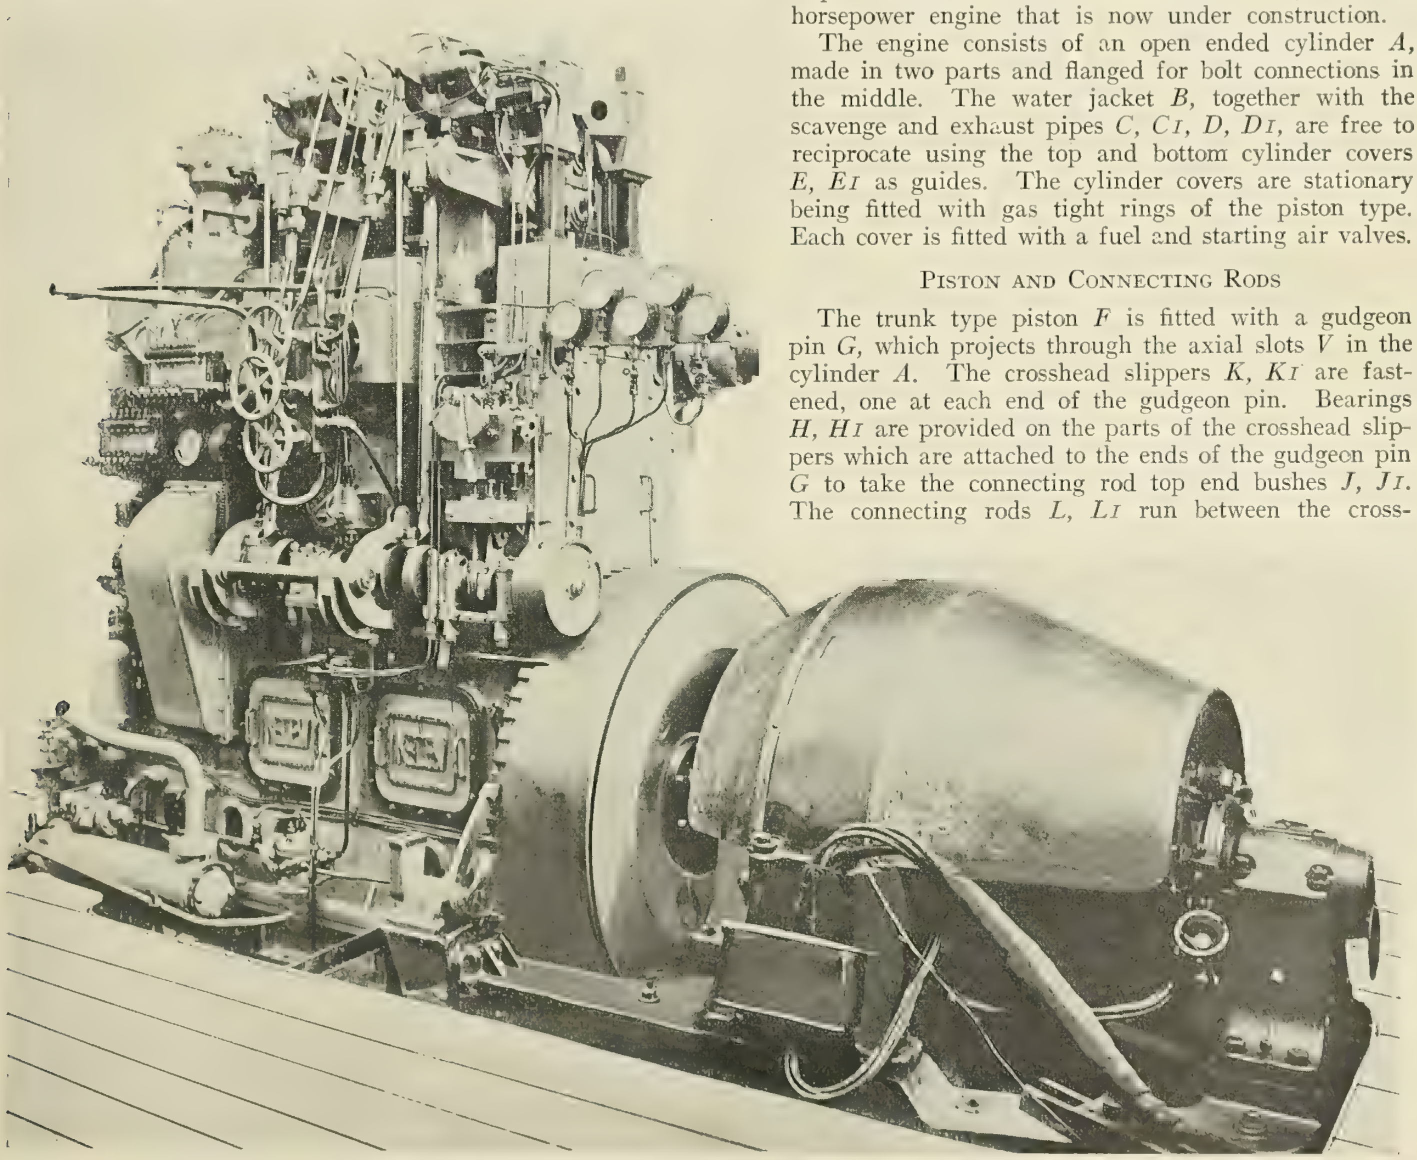

Fig. 1.—The New North British Double Acting Two Cycle Marine Diesel Engine

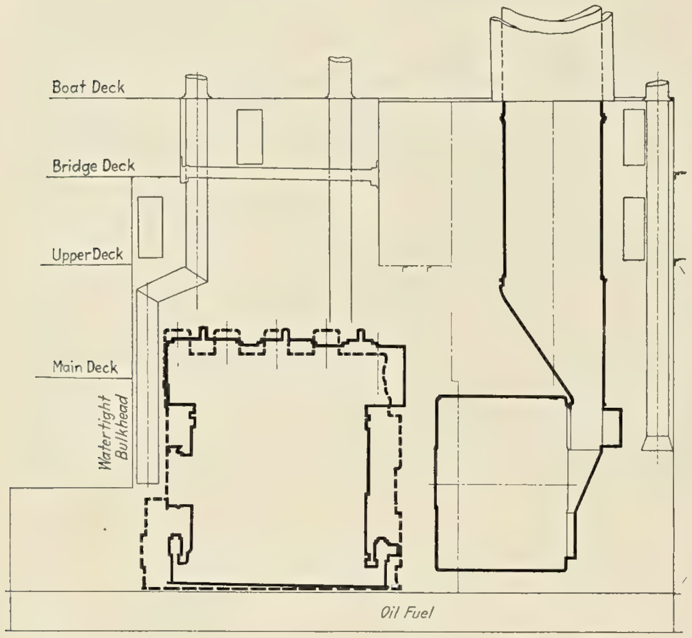
head bearings and the forked end M. The lower end of the forked end M is connected to the crank pin by the bearing N. The crank is designated by the letter P and the shaft bearings by Q, $Q1$.

Cylinder Operation

The special feature of this engine is the moving cylinder which reciprocates synchronously with the piston but through a much smaller distance. The cylinder A, the water jacket B, scavenge pipes C, C_1 and exhaust pipes D, $D1$ are made to reciprocate through the action of a cam shaft driving the cranks and connecting rods S, T, U, Z. The crank Z on the cam shaft drives the rod S, which is connected at the top to the beam levers T, which are pivoted at W. U and $U1$ are links which are attached at their top ends to trunnions fitted to the cylinder and at their lower ends to the levers T, $T1$.

It is to be noted that the cylinder A and its water jacket B travel in the same direction as the piston but at a lower speed. Scavenging ports C_2, C_3, which are supplied by the scavenge air pipes C, C_1, are uncovered by the relative movement of the cylinder A to the cylinder covers E, $E1$.



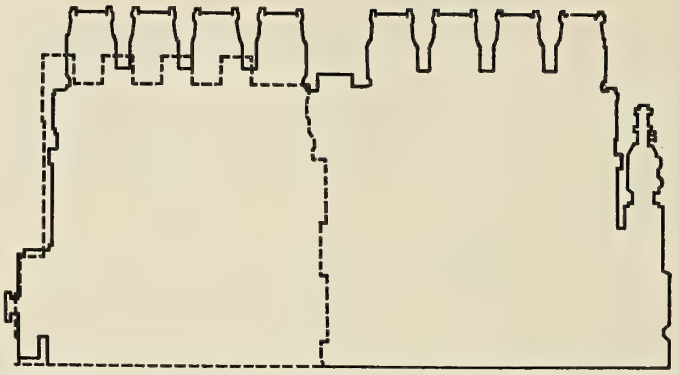


Fig. 3.—Comparison Between Double Acting Diesel Engine (dotted lines) and Four Cycle Diesel (solid lines) of 2,000 Indicated Horsepower

In like manner the relative movements of the piston and cylinder uncover the exhaust ports $D2$, $D3$, through which the exhaust gases pass to pipes D, $D1$. A supercharge of scavenging air is obtained by opening and closing the exhaust ports before the scavenging ports but this has not been found to be essential and will not be embodied in the new engine.

Stuffing boxes are provided in the fixed scavenge supply pipe X for each of the reciprocating scavenge branches and also in the fixed exhaust manifold Y for the moving exhaust branches. In this engine the branches are uncooled but water-cooling is contemplated for the larger engines.

Cylinder Covers

The cylinder covers E, $E1$ are fixed to the main structure. Fuel valves in both top and bottom covers are operated by cams. Both fuel pumps and air starting distributing valves are also driven from the cam shaft. A horizontal lubricating oil pump and a circulating water pump are driven at the end of the crank shaft remote from the fly wheel. The scavenging air pump and a three-stage air compressor are driven from a common crank with forked links.

Advantages Claimed

As is well known, cylinder expansion is one of the hardest things to take care of in big engines. In this engine the cylinder is free to expand longitudinally and radially and in

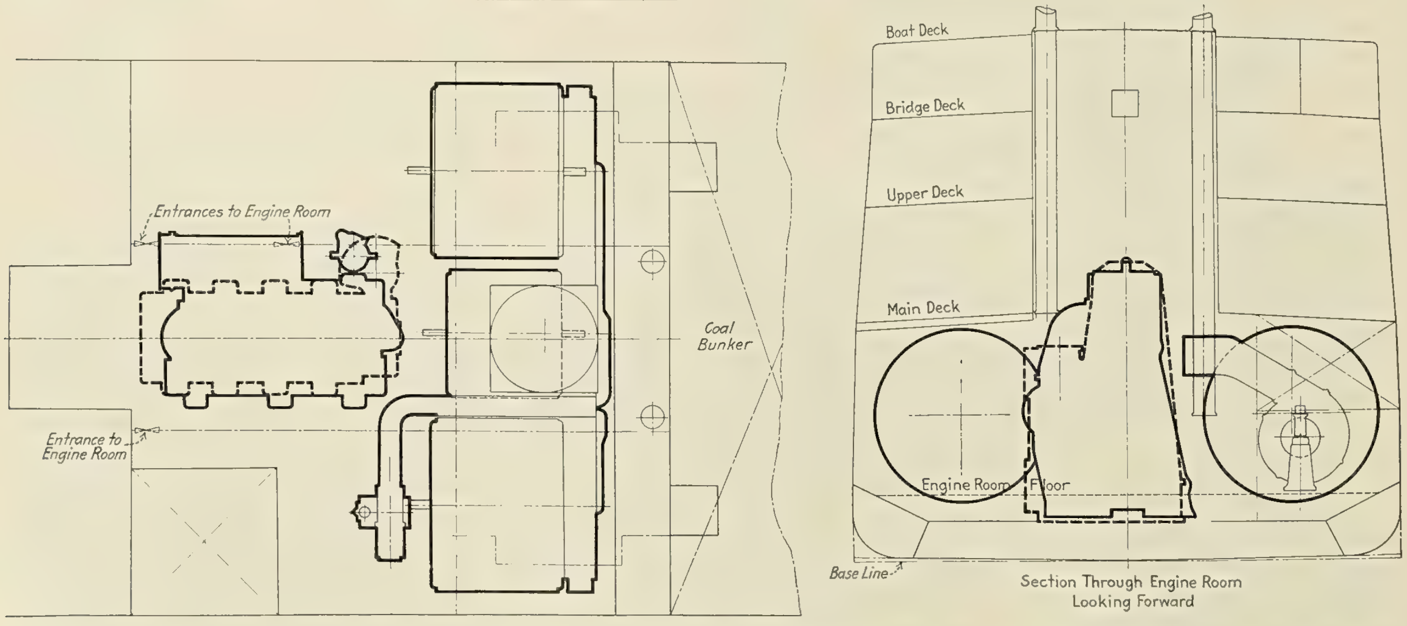

Fig. 2.—Comparison Between Double Acting Diesel Installation (heavy dotted lines) and Corresponding Steam Reciprocating Installation (heavy solid black lines) of 2,000 Indicated Horsepower

the way of combustion space it takes the form of a plain cylinder entirely surrounded by water. It is also to be noted that, due to the motion of the cylinder itself, the rubbing speed of the piston is reduced about 30 percent. The arrangement of scavenging and exhaust ports being at opposite ends of the working cylinder is exceptionally good as through scavenge is obtained and it also does away with certain heat stresses. Another point is that the cylinder covers may be removed without breaking any high pressure cylinder joints.

3-Cylinder, 2,000-B.H.P. Engine

The trials of the engine just described were so satisfactory that the North British Diesel Engine Works has proceeded to construct a 2,000 brake horsepower engine on the two-cycle principle. The engine will have three cylinders with a 24½-inch bore and a stroke of 44 inches. It will run at 100 revolutions per minute. Many improvements in mechanical detail are included in the new design and it is claimed that a remarkable simplicity of construction is obtained in spite of the necessity for providing mechanism for reciprocating the cylinders.

Space Comparisons

The saving in space, which is accomplished by an engine of 2,000 horsepower of this type, as compared with a corresponding steam engine and also with a four cycle single acting Diesel is illustrated in Figs 2 and 3. The four cycle engine, shown in Fig. 3, was installed in the motor passenger liner *Domala* and was also manufactured by the North British Diesel Engine Works. The steam installation shown in Fig. 2 is a single screw steam reciprocating engine of 2,000 indicated horsepower.

The double acting Diesel engine is shown in both cases as a four-cylinder engine having a cylinder bore of 22 inches as compared with 26½ inches in the eight-cylinder four-cycle single acting engine and it is claimed that it weighs just one-half as much. Only half of the main bearings, crosshead bearings and guide shoes are required and only 8 cylinder valves are required as compared with 24 in the four-cycle engine. They both have the same number of revolutions per minute but the four-cycle engine has a piston speed 88 percent greater than that of the sliding cylinder double acting engine.

As compared with the steam engine, it is seen that the double acting engine only takes up the space of the reciprocating steam engine leaving the boiler and bunker space available for extra cargo. With such possible advantages, there is no doubt that the developments in this type of engine will be watched with extreme interest.

---

Electrically Propelled Battleships Win Honors.—Chief honor for excellence in engineering for the year 1921-22 has been awarded the U. S. S. *California*, third of Uncle Sam's electric ships, by Acting Secretary of the Navy Roosevelt. Second honors were awarded the U. S. S. *New Mexico*, the first electrically propelled battleship to float on the seas. The equipment of this vessel is several years old.

Eighteen battleships were considered in making the awards. So that all ships might start the year on as near an equal standing as possible, handicaps were allowed the vessels of older type and with other kinds of propelling apparatus.

In recognition of these high honors, the *California* will have a white "E" painted on her smokepipe, and the *New Mexico* will have a red "E" on her after smokepipe. The *New Mexico* has carried the white "E" for the past year, having won the highest honors in engineering for the year 1920-21. She now passes this honor to the *California*, which was commissioned and entered in the competition about one year ago. Both ships were electrically equipped by the General Electric Company.

The enlisted men of the engineering force on the *California* will each be awarded a prize of $10 by the government, and a letter of commendation, signed by the Secretary of the Navy, will be sent Rear Admiral Henry J. Zeigemeier, commander of the ship. Admiral E. W. Eberle, commander-in-chief of the Pacific fleet, warmly congratulated the officers and men of the *California* on these well earned honors.

A Method of Determining the Natural Periods of Vibration of Ships*

By T. C. Tobin, M. A.

So far as the writer is aware no direct method of attacking this problem has been put forward which is at once adequate and of comparatively easy application along the lines of ordinary drawing office procedure.

The usual method of estimating the fundamental periodicities of a ship's vibration by means of a formula of the character

$$P = A\sqrt{\frac{I}{\Delta L^3}}$$

in which A is an empirical coefficient, leaves much to be desired; for the burden of accuracy in the estimate is borne entirely by coefficient A, which as a rule receives the treatment accorded to so many other empirical constants in naval architecture.

The method of direct attack suggested in what follows is based on the theory of vibrating bars made familiar by the work of the late Lord Rayleigh. For this purpose a ship is conceived as corresponding to a bar in lateral vibration, and it is evident of course that the variation in the distribution of the weight throughout the length of the vessel, as well as the variation of the ship's structure, prevent it from being considered as a uniform bar.

In the usual formula just quoted these variations meet in the one constant A; and the success of the ordinary procedure depends on a knowledge of the fundamental periods of some ship which is sufficiently similar to the one under consideration to ensure that the errors due to differences of weight and strength distribution are negligible. The necessary condition holds in very few cases, and the formula affords no means of estimating the periods for any novel distribution. In the procedure to be outlined the variations are dealt with on their own merits.

Were the ship a uniform bar the frequency of its periods would be given by:

$$P = \frac{n^2}{2\pi}\sqrt{\frac{E\,I\,g}{\Delta L^3}}$$

where E is Young's modulus for the material of the structure; I the moment of inertia of the cross section of the bar; Δ the weight in tons; L the length in feet; g the gravitational constant; and n a numerical magnitude depending on the mode of vibration.

When the mass and rigidity vary along the length of the bar, the frequency is modified to p where

$$p = P\sqrt{\frac{1 + \delta c/c}{1 + \delta a/a}} \quad \text{..............................(See Appendix I)}$$

This may be taken to be true to a close approximation, so long as the type of vibration remains approximately normal.

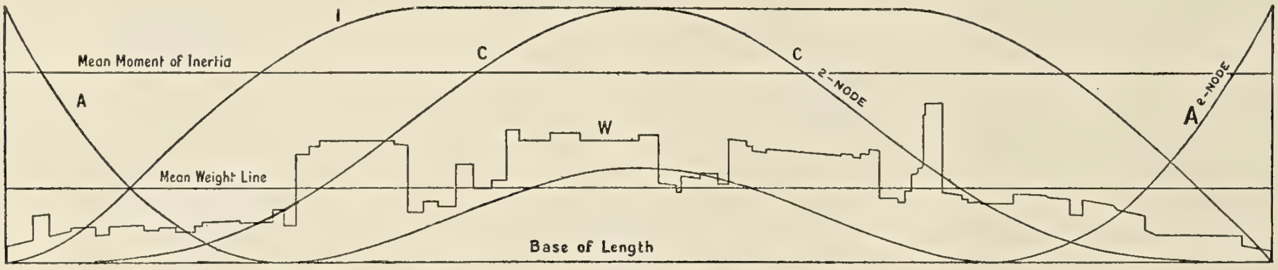

Fig. 1

This modification was originally devised to meet the case of small variations of mass and flexural rigidity, and it does not necessarily follow that the method would give close results, when the variations are somewhat large. It appeared, however, to the writer that for a large body, such as a ship, there was a possibility of the vibrations not departing from the normal to any great extent, and that the application of this formula would give a determination of the periods which would be useful for estimating purposes.

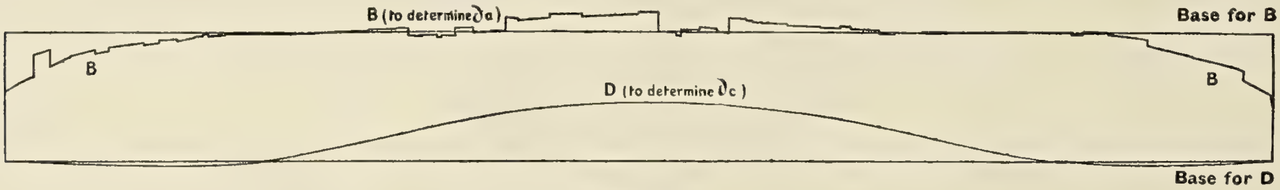

Fig. 2

The quantities a, δa, c, δc, are determined as follows: The weight distribution curve W, Fig. 1, is plotted for the vessel, and the mean weight line drawn; the auxiliary curve A is also drawn covering the same range as the weight curve;

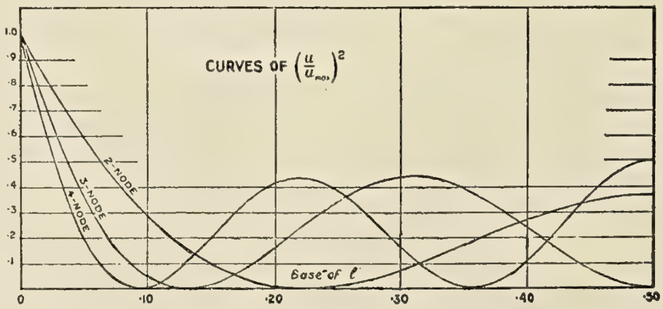

Fig. 3

*Paper read at the sixty-third session of the Institution of Naval Architects, London, April, 1922.

the difference of the ordinates of the weight curve and the mean weight line at any given point in the length is multiplied by the ordinate of the auxiliary curve A at that point and the series of products thus obtained plotted as a curve over the whole range, as B, Fig. 2. The area of the B curve is integrated by any convenient method, mechanical or otherwise, and this integral is the quantity δa; the integral of the auxiliary curve A multiplied by the integral of the weight curve, both taken over the range of length, gives the quantity a; hence dividing one by the other we obtain $\frac{\delta a}{a}$.

In a similar manner $\frac{\delta c}{c}$ is obtained, by using, instead of the weight curve, a curve giving the distribution of the moment of inertia (I) throughout the length, and another appropriate auxiliary curve C, to obtain the curve D in Fig. 2.

The ship may be compared to a bar which has both ends unconstrained, or in the Rayleigh nomenclature a "free-free" bar. Such a bar may of course vibrate in a two-node, three-node, four-node, . . . r-node manner.

For each mode of vibration a particular auxiliary curve for each of the δa and δc determinations is required; those associated with the δa for the two-, three- and four-node vibrations are shown in Fig. 3, and those associated with δc in Fig. 4.

As a test of the utility of the methods it was applied to two ships of widely differing types.

The first case was that of an oil tanker, particulars of which were published in the *Transactions of the Society of Naval Architects and Marine Engineers* in 1915.* Investigations carried out on this vessel showed that the fundamental period had a frequency of 76 vibrations per minute; while calculations carried out on the lines which have been indicated gave the frequency of the two-node vibrations as 75.4 per minute, on the assumption that Young's modulus had the value 12,500 inch-ton units.

The second case was that of a large passenger liner. An extensive series of records made with a Schlick pallograph showed that under certain observed conditions of loading two clearly defined periods of vibration were observable which appeared to correspond to fundamental periods of the ship, and these had frequencies of 58.8 and 150 per minute.

The calculation for a two-node vibration carried out by the proposed method gave 59.4 as the corresponding number of vibrations per minute; the three-node calculation resulting in the figure 148.7; the value of Young's modulus E again being assumed to be 12,500.

In arriving at these figures a correction was made for the rotatory inertia effect in the manner suggested in Appendix II. For the two-node vibration it was of the order of 2½ percent, and for the three-node about 3¾ percent. The as indicated in Appendix III., and found to be quite neg- effect of the varying local displacement was also estimated

*"The Period of Vibration of a Steamship," by W. Gatewood.

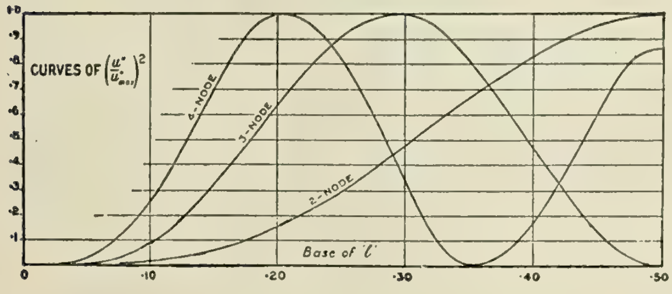

Fig. 4

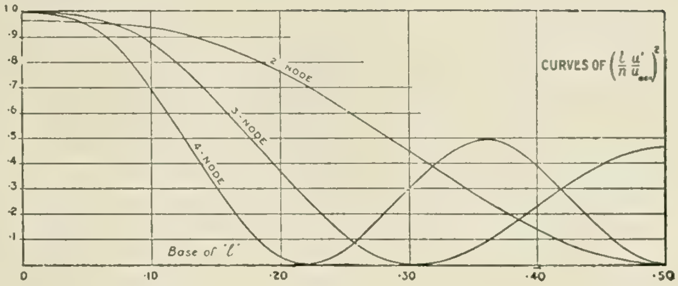

Fig. 5

ligible as might have been expected; the mean value of F in this case was about 2.6 tons.

Had second order terms expressing the interaction of modified two-node and three-node types of vibration been taken into account it would have resulted in a slight shortening of the three-node period and a slight lengthening of the two-node; this would have probably brought the ratio of the two periods more nearly into correspondence with the observed values. As it is, the correspondence is close enough to suggest that the method may prove a reliable one for investigating the values of the two gravest modes of vibration.

It is interesting to note that the same value of E fits the solution in both cases; and this is the only quantity whose value is directly assumed. From the opposite point of view it may be regarded as in some sense a corroboration that this value of E is an approximately correct one to use with ship structures of this type, when the values of I are estimated in the usual manner.

A calculation of the four-node vibration of the liner was also made, giving as a result a frequency of 269 per minute; the observed vibrations of the vessel gave, however, no decisive indications for this third fundamental mode of vibration. The value of the rotatory inertia correction in this case was of the order of 7½ percent.

It would be extremely interesting to have additional verification that the method gives results in harmony with observed vibrations of ships; unfortunately the time at the author's disposal did not permit him further to test its validity, but it is hoped that what has been said will be sufficient to indicate that the procedure merits the attention of those who may have to deal with concrete cases of vibration.

Appendix I

If the type of vibration of a "free-free" bar is considered as a deviation from the normal we may proceed as follows: The expressions for the kinetic energy, T, and the potential energy, V, for a uniform bar may be written in the general form:

$$2T = a\,\phi^2$$
$$2V = c\,\phi^2$$

where ϕ is the normal coordinate corresponding to the type of vibration, and a and c are the mechanical functions.

If now the mass of the bar is altered in its longitudinal distribution, and the moment of inertia is also varied, these expressions become

$$2T' = (a + \delta a)\,\phi^2$$
$$2V' = (c + \delta c)\,\phi^2$$

on the assumption that the type of vibration is not materially altered.

If P is the frequency for the uniform bar, and p that for the modified bar, we then have

$$P = \sqrt{\frac{c}{a}};\quad p = \sqrt{\frac{c + \delta c}{a + \delta a}}$$

$$\text{i.e., } p = P\sqrt{\frac{1 + \delta c/c}{1 + \delta a/a}}$$

so long as the type remains approximately normal.

In the case of a doubly free bar we have the type:

$$y = A\,u\cos\left(\sqrt{\frac{EI}{m}}\cdot\frac{n^2}{l^2}\cdot t + \epsilon\right) = A\,u\,\phi$$

where u is the normal function satisfying the equation:

$$\frac{d^4 u}{dx^4} = \frac{n^4}{l^4}\,u$$

A being an arbitrary constant; E, Young's modulus; m the mass per unit length; I the moment of inertia of the section, and l the length of the bar. We have also:

$$a = m\int_0^l u^2\,dx \quad\text{and}$$
$$c = EI\int_0^l u''^2\,dx \quad\text{for the uniform bar}$$

and hence the variational values:

$$\left.\begin{aligned}\delta a &= \int_0^l \delta m \,.\, u^2\, dx \\ \delta c &= \mathrm{E}\int_0^l \delta \mathrm{I} \,.\, u''^2\, dx\end{aligned}\right\}\text{for the modified bar}$$

where $u' = \dfrac{du}{dx}$; and $u'' = \dfrac{d^2u}{dx^2}$

It would be possible, of course, to find

$$\int_0^l m\, u^2\, dx \text{ and } \mathrm{E}\int_0^l I\, u''^2\, dx$$

and the periodicity derived from this giving

$$p = \sqrt{\frac{\mathrm{E}\int_0^l \mathrm{I}\, u''^2\, dx}{\int_0^l m\, u^2 dx}}$$

but as u and u'' apply strictly speaking only to a uniform bar, and not to the bar with varying I and m, it is considered a sounder method of procedure to calculate as indicated above by δa and δc.

Auxiliary curves giving the variation of the values of u^2 and u''^2 over the range of length are required, and these were calculated from the differential equation given above together with the associated equation:

$$\cos n \cosh n = 1$$

The values expressed as ratios of the maximum value in each case are shown in Figs. 3 and 4 in the form of curves, and the numerical values are given in Appendix IV.

The values of n for the two-, three- and four-node vibration are, respectively, 4.7300, 7.8532, 10.9956.

Appendix II

To estimate the effect on the period due to the rotatory inertia we may use a modified expression for the kinetic energy, viz.:

$$2\,\mathrm{T} = \int_0^l m\, y^2\, dx + \int_0^l \mathrm{I} \left(\frac{d}{dt} \,.\, \frac{dy}{dx}\right)^2 dx$$

$$= p^2 \,.\, \sin^2 p\, t \left[\int_0^l m\, u^2\, dx + \frac{n^2}{l^2}\int_0^l \mathrm{I}\left(\frac{l\, u'}{n}\right)^2 . \, dx\right]$$

where $y = u \cos p\, t$,
$\dot{y} = -u\, p \,.\, \sin p\, t$,
$m =$ mass per unit length of curve of loads,
$\mathrm{I} =$ mass moment of inertia per unit length.

Curves of I, u^2 and u''^2 are wanted, the two latter in terms of the same units. I refers to the mass of material which has rotatory inertia, excluding the masses not rigidly attached to the ship; it will not therefore involve as a rule the total mass of the vessel.

For estimating purposes and to simplify the calculations it was assumed that the masses not rigidly attached to the structure were distributed uniformly over the depth of the section at each point; their moments of inertia then became equal to $\dfrac{m\, d^2}{12}$ where d is the depth of the section taken as uniform throughout the length and equal to the molded depth plus one-third of the mean sheer.

This assumption tends to increase the value of the correction, that is, to over-estimate it rather than under-estimate it. Curves of $\left(\dfrac{l\, u'}{n}\right)^2$ are given in Fig. 5 for the same unitary value as the corresponding curves of u^2 in Fig. 3; the quantity $\left(\dfrac{l\, u'}{n}\right)$ being used in preference to u as being more readily comparable with u. The numerical values are given in Appendix IV.

The frequency is then altered in the ratio:

$$\left[1 + \frac{\dfrac{n^2}{l^2}\displaystyle\int_0^l \mathrm{I}\left(\frac{l\, u'}{n}\right)^2 . \, dx}{\displaystyle\int_0^l m\, u^2\, dx}\right]^{-\frac{1}{2}}$$

Appendix III

An estimate can be made of the effect on the period resulting from the varying local displacement due to the motion, by suitably modifying the expression for the potential energy.

If it is assumed that for a large portion of the length the vessel is wall-sided in the neighborhood of the waterline, the increase and decrease of buoyancy force will be, to a first approximation, proportional to the ordinate of the normal function.

This will have the effect of adding a term to the V function of the form $\frac{1}{2}\,\mathrm{F}\, u^2$, where F is the force called into play per unit length. We have, therefore:

$$2\,\mathrm{V} = \int_0^l \mathrm{E}\,\mathrm{I}\, u''^2 \,.\, dx + \int_0^l \mathrm{F}\, u^2\, dx$$

The calculation may be simplified and the order of the correction discovered by assuming F constant throughout the length and equal to an estimated mean value.

Testing the New Pumping Equipment of the New York City Fireboat Thomas Willett

On July 17, tests were made of the new pumping equipment that has been installed on the veteran New York City fireboat *Thomas Willett.* This equipment consists of two 600 brake horsepower Westinghouse steam turbines, of the mechanical drive type, each of which is direct-connected to a 12-inch Lea-Courtney double-suction, volute fire pump.

The average performance of the pumps during the test, which lasted 6 hours, was 9,215 gallons per minute at 150 pounds pressure and 7,410 gallons per minute at 175 pounds pressure, when operated singly, and 4,690 gallons per minute at 300 pounds pressure when connected in series and operated together. In all tests, the Underwriters' requirements were greatly exceeded. The steam pressure was 185 pounds per square inch at the turbine and the suction head 4 pounds per square inch.

The equipment was purchased for the City of New York by Fire Commissioner Thomas J. Drennan. Similar equipment has been ordered to replace the present pumps in the *James Duane,* another fireboat.

United States Navy's Research of Ship Bottom Paint

By N. E. Adamson*

Second and concluding installment of an article prepared from the author's notes on research pertaining to ship bottom paints during the past 12 years, augumented by data drawn from the files at the Norfolk Navy Yard, where most of the Navy's research on this subject has taken place. Because of the great volume of data, a brief description of the tests and the history of the research is given rather than a technical discussion of the subject. For obvious reasons the trade names of proprietary paints and materials are omitted. This article was originally read before a committee of the Society for Testing Materials.

FROM 1911 to 1921 was a period of testing various ingredients in bottom paint formulæ designed after the Norfolk formulæ 17 and 19. These tests included approximately 350 preliminary investigations made by submerging steel plates as well as a great number of service tests on ship bottoms, all of these tests being conducted under the writer's observation. In order to follow the data it is well here to insert the formulæ for Norfolk ship bottom paints used at the beginning of this period. They were:

Ingredients	For 100 gallons Anti-corrosive	Anti-fouling
Grain alcohol	74¾ gallons	64 gallons
Gum shellac, Grade A	79½ pounds	137½ pounds
Turpentine	6⅜ gallons	10½ gallons
Pine tar oil	6⅜ gallons	10½ gallons
Zinc oxide, dry	284½ pounds	137½ pounds
Zinc dust	95 pounds	00
Indian red, dry	00	137½ pounds
Red mecuric oxide	00	47½ pounds

An outline of the tests pertaining to each ingredient is as follows:

Testing Ingredients in the Ship Bottom Paints

Since 94 percent pure grain alcohol is obtainable without the payment of internal revenue, it has not been necessary to consider wood alcohol for the sake of cost. The present rate is $0.35 per gallon. However, to prevent tampering with the paint to extract the alcohol for beverage purposes, the alcohol is now denatured by adding a very small percentage of croton oil and a red dye (fuchsin). So far as has been observed this has not affected the properties of the paints.

Gum shellac, a material obtained from India, was once used extensively in commercial ship bottom paints but due to the manner in which it is produced, it being an excretion from certain species of insects, the supply is limited. In 1911 the Navy Department could obtain an ample supply of a very excellent grade in which the flakes were large, clear and hand free. Since that time this grade has been required for other industries and it is now very difficult for the paint manufacturer to get it even if he could afford to pay the price.

The lowering of the grade of gum shellac affects seriously the protective properties of the paint. A test made from September, 1912, to April, 1913, on the bottom of the U. S. S. *South Carolina* showed that bottom paints made with a slightly inferior grade of gum shellac fell off the bottom, while paints made from the better grade did not.

During the past four years efforts have been made to successfully substitute pure garnet lac for gum shellac. These experimental paints would give good results if it were possible to get them applied, but the spirit varnish made from garnet lac acts in a very peculiar way toward the other ingredients. The pigments in the anti-corrosive paint rapidly settle and harden, while the anti-fouling paint congeals within 24 hours to such an extent that it cannot be applied with a brush. It has been found that the addition of approximately one ounce of potassium hydroxide per gallon of paint prevents these peculiarities, but it still remains uncertain whether the hydroxide accelerates corrosion of the steel painted. This matter is still under investigation.

Shellac wax, bee's wax, rosin and pine tar pitch have been used separately and in conjunction with gum shellac or garnet lac and have given negative results. A pure grade of T.N. gum shellac has been tested, but in none of these efforts have results been equal to results from using the high grade gum shellac.

Rosin has especially been of interest because of its low cost and because it is used with apparent success by some of the foreign navies, but rosin, like gum shellac, has many grades. Possibly the right grade has not yet been used in the experiments. The grade that has been used gives a weak film that cracks and softens under water and the paints fail because of rust within three months.

The use of rubber to strengthen the film produced by the lower grade gum shellac in anti-corrosive paint, over which were applied Norfolk anti-fouling or an experimental anti-fouling paint, showed that the rubber had no effect on the anti-corrosive properties but did improve the anti-fouling properties of the paints applied over it. Here it may be stated that in 1907 a naval officer observed that an iron caisson at Pensacola, Fla., had not fouled although it had been in the water several years. This caisson was coated on the underwater part with rubber. Tests made with red gum (Yacca gum) as a substitute for gum shellac gave excellent results.

The use of turpentine (spirits) instead of the cheaper petroleum spirits is not believed to be warranted. During 1913 and 1914 tests on four bottoms, made by quartering and painting diagonally opposite quarters with bottom paints containing petroleum spirits instead of turpentine, failed to show any difference. On one of these bottoms (the U. S. S. *Michigan*) the test was repeated and still no difference was obtained.

Pine tar oil is used in the paints to give slight flexibility to the film. However, pine tar oil contains much free pyroligenous acid which attacks first the metallic zinc in zinc dust used in anti-corrosive paints. In 80 days the paint evolves a volume of gas which, at atmospheric pressure, is equal to the volume of paint. This accounts for the tendency of the anti-corrosive paint to be forced out of leaks around the filling hole of containers. The paint cannot successfully be stored in wood barrels for the same reason.

Pine oil has been used with varying degrees of success as a substitute for the pine tar oil, the turpentine and a part of the alcohol. From a technical standpoint such paint is better than the Norfolk paints, but the odor of the pine oil is obnoxious. The men applying the paint complain of its effect. This probably accounts for its use being abandoned after several vessels had been painted.

It would be highly desirable to substitute for the pine tar oil in the Norfolk formulæ an oil which would give the same flexibility to the film and which would be free of acids and

* Assistant shop superintendent, United States Navy Yard, Norfolk, Va.

disagreeable odor. Castor oil, used to the extent of 2 gills per gallon of paint, causes blistering of the film, but these small blisters do not seem to be detrimental. The Norfolk paints containing the castor oil are superior, during the first seven months' service. Boiled linseed oil, used in the same way the castor oil was used in the paints, gives negative results. The films crack and rust starts within two months.

A medium grade of zinc oxide (American XX) is used in Norfolk paints but a slightly leaded zinc has proven equally as efficient so far as results on submerged plates show. The sulphate of lead in the leaded-zinc should not exceed ten percent. When thirty percent sulphate of lead, leaded-zinc is used the results are negative and the paint pigments settle hard in the containers. It would seem desirable from the standpoint of cost and improvement of the quality of paint to reduce the amount of zinc oxide and add an inert pigment such as silica. Silica, as will be mentioned later, is an excellent pigment for ship bottom paints.

Zinc dust is supposed to be the ingredient in the anti-corrosive paint which prevents corrosion. The electrolytic theory for rust is adhered to in this supposition, it being held that the metallic zinc which constitutes 85 percent of the zinc dust, being electro-positive to iron, forms galvanic couples to prevent the rust. If this supposition is correct, as it seems to be, it would seem to be desirable to increase the proportion of zinc dust. It has been noted that rust is usually prevented as long as the particles of zinc dust are present in the film and that rust starts soon after these particles have disappeared. Powdered metallic zinc gives better results than zinc dust, which is only 85 percent metallic zinc, but is expended more rapidly. The original Norfolk formula required a larger proportion of zinc dust (metallic zinc) and apparently produced a better paint than the present standard. Of course there is the ever present liability of zinc dust to spontaneous combustion, a feature that should be considered separately from a discussion of this character.

Indian red is possibly the least influential ingredient in the bottom paints, yet there are possibilities of much being done in the selection of the proper quality. Several kinds have been tested, some giving slightly positive and some decidedly negative results. It is believed that the success of the British Navy paints is due in part to a fortunate selection of their iron oxide pigment which is obtained from ore mined in England. Again, it may be that Indian red is altogether the wrong pigment to use with the zinc oxide because a weak galvanic action is set up between particles of the two pigments but it is used in Norfolk anti-fouling ship bottom paint to give body and to make the color distinctly different from the anti-corrosive paint, the latter property being highly desirable for insuring that all parts of the ship's bottom are coated.

Finally the toxine, mercuric oxide, is to be considered. Compounds of mercury are used, or have been used, in most anti-fouling paints for steel bottoms. Only red mercuric oxide was once used in Norfolk anti-fouling, but of recent years red or yellow mercuric oxide has been used as the toxic qualities of the two, so far as service is concerned, seem to be equal. Originally 47½ pounds per 100 gallons of paint were used but this has been increased so that now 75 pounds per 100 gallons of paint are used. This change occurred in August, 1914, after considerable testing on ship's bottoms as well as on submerged plates.

Mercuric oxide is a very heavy pigment, its specific gravity being entirely out of proportion to all the other ingredients of the paint. This causes the pigment to settle rapidly and, in order to get an approximately even distribution of the pigment on a bottom, it is necessary to do much stirring both before the paint is taken from its shipping container and after it is poured into buckets from which it is applied. After the paint is applied there is only a shellac film holding it and as the shellac film usually softens in 48 hours after submersion it is reasonable to expect that much of the mercuric oxide is then lost.

During November, 1914, the bottom of the U. S. S. *Paulding* was found to be clean of fouling except for scattered bunches of hydroids about five inches long. The paint under these hydroids was found to be free of mercury.

Copper salts have been considered unsuitable on steel hulls because of the known effect of the presence of metallic copper adjacent to submerged surfaces of steel (or iron). However, some very interesting results have been obtained when using copper salts instead of mercuric oxide in Norfolk paint. From May to October 1921, a submerged plate showed that cuprous oxide would not prevent barnacles from becoming attached, but the experimental film remained harder and freer from rust than did the standard film. Copper cyanide gave slightly positive results during a ten-month (January to October) submersion test, but the film showed early blistering followed by small beads of rust. When copper cyanide was used as the toxine in a formula varying greatly from the Norfolk formula the results were decidedly negative and the film caught the first crop of barnacles and hydroids.

Arsenic trioxide and orpiment have also been tried and gave negative results. The former is possibly too soluble in water and the latter gave fair results for two months (February and March) but was not effective as a toxine when the barnacle season opened.

Paris green has been tried in a number of tests. It is a most excellent pigment and toxine but unless it is supplemented with mercuric oxide, or an equivalent toxine, it does not prevent fouling. When so supplemented the results are decidedly positive. Its relative cheapness permits its use as a part of the body pigment and as such it is quite suitable.

Mercuric linoleate, copper linoleate, zinc cyanide and cuprous hydrate have been tested in a preliminary way, in one submerged plate test, and each has failed to prevent fouling by barnacles.

The conclusion can logically be drawn that in order to prevent fouling by poisoning it is necessary to use a toxine for organisms of the animal kingdom and a toxine for organisms for the vegetable kingdom. So far as the writer's experience goes no one substance has been found toxic to both that can be used effectively in an anti-fouling ship bottom paint. This statement does not take into consideration those paints which prevent fouling by exfoliation, with which very little experience has been had. One test has been made with a heavy petroleum grease applied over bottom paints. The grease was supposed to prevent attachment of fouling by preventing secure attachment. The results were negative and the grease caused the anti-fouling paint beneath to crack and flake.

In December, 1915, an effort was made to analyze the results from approximately 75 tests to determine the relative merits of various pigments used. The tests were made on submerged plates, each being examined monthly for eight months. Two coats of anti-corrosive paint and one coat of anti-fouling paint were applied in each case. The results were graded on the basis of ten being perfect and the average grade for each pigment was determined as the average grade on all paints in which the pigment was used. The same vehicles as are used in Norfolk paints were used in most of these tests. The results were:

Pigment	Anti-corrosive	Anti-fouling
Zinc oxide	4.2	3.74
Silica	5.2	3.65
Blanc-fixe	4.	5.2
Artificial vermillion	3.11	2.87
Indian red	..	3.2
Orpiment	..	4.86
Paris green	..	5.4
Proto oxide of copper	..	4.1

These grades indicate that silica is an excellent pigment for an anti-corrosive paint and that blanc-fixe is an excellent

pigment for anti-fouling paint. They also indicate that Indian red is not a desirable pigment for anti-fouling paint. Red lead in an oil paint, in a flat paint and in a spirit varnish paint has been tried as a primer for anti-fouling paint; that is, as an anti-corrosive paint. It has also been tried in combination with basic sulphate of lead. In all these tests the results have been negative. However, red lead oil paint applied on hulls while building, and which has at least three months to dry before ship bottom paints are applied, gives better results.

Tests of Vehicles

The determination of the proper vehicle for ship bottom paints is equally as important as the determination of the proper pigments. Some effort has been given to determine the proper ratio of gum shellac to volatiles, but the data obtained are not sufficient upon which to base a conclusion. It is believed, however, that the ratio should be greater for anti-fouling than for anti-corrosive paint. The anti-fouling must hold heavy toxines and must assist in binding the anti-corrosive paint's pigments to the ship's bottoms. Other kinds of vehicles have been tested, for example, an anti-corrosive paint in which a linseed oil product was used with Portland cement as the pigment. The results were excellent, but the drying time was prohibitive. The linseed oil compound used without pigment (as a waterproof coating) and applied next to the steel gave poor results.

Chrome yellow used with this oil compound formed an excellent anti-corrosive paint, but dried too slowly. Chrome yellow used in a spirit varnish anti-corrosive gave poor service.

Asphalts were used as the binder for anti-corrosive and anti-fouling paints on one plate and all the paint came off within three months. Asphalt bottom paint tests made at a naval station in the Philippine Islands gave much better results. Coatings of shellac between the anti-corrosive and anti-fouling paints prove ineffective.

One very interesting test of an intermediate varnish coat was made by applying a hard gum varnish over the seams and rivets of a bottom before applying Norfolk anti-fouling paint. When the vessel was again docked it was clean of fouling except where the hard gum varnish had been applied. Here was found a heavy growth of hydroids and crustaces where the varnish had caused the anti-fouling paint to check and fall off. The bottom had a checker board appearance.

Whatever type vehicle is selected for the anti-fouling paint, the same type vehicle should be used in the anti-corrosive paint. There should not be a marked difference in elasticity between the two paint films.

Combination Ship Bottom Paint

It was suggested above that possibly the properties of an anti-corrosive and of an anti-fouling ship bottom paint could be combined in one paint. The belief that this can be done is based upon the fact that it is the built-up film on a bottom that gives the best protection. By built-up film is meant that film produced by applying fresh paints over old paints. When a ship is placed in drydock the slime and fouling are removed. This can usually be done by washing or by scraping with square point shovels. The paint adhering to the bottom is not removed. The bare spots are then touched up with anti-corrosive paint, after which the bottom is given one or two complete coats of anti-corrosive over which is applied the anti-fouling paint. In time there is built up a comparatively heavy coating of paint consisting of alternate layers of anti-corrosive and anti-fouling. If a coating consisting of layers of different paints gives good service, why would not a coating in which the different paints are more thoroughly mixed give good services?

Often a ship bottom is painted when it is in a fair condition in order to assure that the condition will be maintained until the time for the next docking. One coat of anti-corrosive and one coat of anti-fouling is the minimum that can be applied to protect against both rust and fouling. If a combination paint were available one-half of the labor and time could be saved by applying one coat of the combination paint. The demand for such a paint is great. When it is produced, and eventually it will be produced, the ship bottom paint trade will have to conform to the demands.

The following formula has been tested on a submerged plate from July to January, during which period two coats of it gave better service than did two coats of Norfolk anti-corrosive and one coat of Norfolk anti-fouling paints. The combination paint film was hard and clean of fouling and rust at the end of six months' exposure.

To make 25 gallons:

Grain alcohol	13¾	gallons
Gum shellac	40	pounds
Pine oil	2½	gallons
Zinc oxide	30	pounds
Silica	30	pounds
Blanc-fixe	30	pounds
Paris green	15	pounds
Mercuric oxide	10	pounds

This paint weighs approximately 11 pounds per gallon, and dries equally as fast as do the Norfolk paints. It should be borne in mind, however, that this formula has been tested on only one submerged plate. It has not been tested on a ship's bottom.

Referring again to the merit of a built-up film, it can be stated that in making tests attention should be given to the effects produced by a built-up film. It is not sufficient to condemn a paint because the first coats on a steel plate do not prevent rust for a period of six months. The test should be continued by removing the rust and fouling and repainting. In this way a film is built up which possibly will give the desired service. Again, when painting sections of a bottom with an experimental paint, the results from the first painting are often not due entirely to the experimental paint, but to the built-up film consisting of the experimental paint and the paints previously used. These facts are so elementary that wonder is had at conclusions sometimes drawn from tests.

Tests Now in Progress

During the past ten months there has been a renewed activity in tests of ship bottom paints. Preliminary tests, to find suitable vehicles other than the present standard vehicle, indicate that aeroplane dope is not suitable. A spar varnish containing both linseed and tung oil apparently is unsuitable and an ester resin, dissolved in benzol, presents some likelihood of having merit, but the tests have not advanced sufficiently to warrant any conclusion.

A series of interesting tests is in progress at Beaufort, North Carolina, where the Navy has a chemist stationed temporarily in the Bureau of Fisheries Laboratory. These tests will be continued on steel plates submerged at the Norfolk Navy Yard.

Other tests are being made of ship bottom paints having barium salts as the toxine and several vessels are now painted with such paint on two quarters of the bottom.

In addition copper cyanide is being further investigated as is also cuprous oxide.

Conclusion

The problem of finding the best formulæ is an intensely interesting one and the solution is not found when a pigment or pigments are found which are toxic to all forms of marine growth. An effort has been made in the foregoing to show that the problem covers physical as well as chemical properties of the paint film.

In 1906 the Navy used approximately 25,000 gallons of ship bottom paint. The Navy now uses approximately 200,000 gallons of ship bottom paint per year.

A recent review of reports during the past 4 years showed

that the effectiveness of the anti-corrosive paint is good for a period of from 12 to 18 months and the effectiveness of the anti-fouling paint is good for 9 months. Considering averages, vessels out of dry dock nine months are in as good condition as those out of dock only six months.

Corrosion develops slowly between the twelfth and eighteenth month and rapidly after that.

These periods are suggested from the records of 303 examinations; 134 for vessels out 6 months, 64 for vessels out nine months, 66 for vessels out 12 months, 27 for vessels out 18 months and 12 for vessels out 24 months. The records cover all types of vessels plying in all waters traversed by United States Naval vessels.

Results of Experiments

Table 1 contains information of tests conducted at the Norfolk Navy Yard with 21 experimental paint compositions. Some of these paints were tested on submerged steel plates, some on the bottom of launch number 270 and others on the bottoms of coal barges numbers 69 and 74.

The submerged steel plates were painted with two coats of anti-corrosive paint and one coat of anti-fouling paint. The results were:

Formulæ	Period of Submersion	Results
No. 1 A. C. and No. 2. A. F.	May 30, 1906 to July 30, 1906	Poor. Paints soft and covered with barnacles and rust cones.
No. 1 A. C. (No anti-fouling)	May 31, 1906 to July 30, 1906	Poor. Covered with rust, barnacles and grass.
Commercial brand A. C. and A. F.	May 31, 1906 to July 30, 1906	Fair. Few barnacles, no grass, slight rust.
Commercial brand A. C. and A. F.	May 31, 1906 to Dec. 20, 1906	Many large barnacles. Much corrosion in form of black oxide. Paints soft.
No. 3 A. C. and No. 4 A. F.	June 14, 1906 to Dec. 20, 1906	Paint soft. Few scattered barnacles and large rust cones. No grass.
No. 5 A. C. and No. 4 A. F.	June 21, 1906 to Dec. 20, 1906	Large cracks in film in which rust developed. No other rust on plate. No barnacles. No grass.
No. 6 A. C. and No. 7 A. F.	Aug. 9, 1906 to Dec. 20, 1906	Few barnacles. Little grass. Much slime. Small amount of rust. Oil sweats out of film. Paint soft. Fair condition.
No. 12 A. C. and No. 13 A. F.	Sept. 21, 1906 to Dec. 20, 1906	Slight blistering. No rust. No fouling.
No. 20 A. C. and No. 21 A. F. (plate polished)	Oct. 20, 1906 to Dec. 20, 1906	No fouling. Rust cones started. Slight pitting noted after the paint was removed.

Launch No. 270 was painted September 4, 1906, and the bottom examined December 22, 1906. The bottom had been galvanized but the galvanizing had worn off at the time of the test. Sections 12 feet long extending from the waterline to keel on one side were used for these tests. The results were:

Formulæ	Results
No. 3 A. C. and No. 4 A. F. (HgO added to 2nd and 3rd coats)	No rust. No grass. Few barnacles. Paint in excellent condition when first taken out of water but began to peel in 24 hours after exposure to air.
No. 5 A. C. and No. 9 A. F.	Few barnacles. No grass. Few rust cones where paint was chipped off. Paint scales when exposed to the air after submersion.
No. 3 A. C. and No. 4 A. F.	Conditions about the same as first item. There were small rust cones where paint was chipped off.
No. 5 A. C. and No. 9 A. F.	Numerous barnacles and moderate amount of grass. No rust. Paint hard and did not scale on exposure to air.
No. 10 A. C. and No. 11 A. F.	No rust. No grass. Few barnacles. Paint hard but scaled upon exposure to air after submersion.
Commercial brand A. C. and A. F.	Paint off from numerous spots, but remaining paint was hard. General corrosion started. Numerous rust cones. Numerous barnacles, moderate amount of grass. Paint does not scale on exposure to air.

General Comparison

The anti-fouling test paints, with the exception of Number 9, were effective. All the paints were less effective at the waterline than well below the waterline. Where submerged all the test paints proved superior to the commercial paint. All the paints scaled on exposure to air, after submersion, except those designated as Numbers 5 and 9 and the commercial paint.

Coal barge Number 69 was painted September 23, 1906; examined January 18, 1907, and again on October 3, 1907. It was sunk in Hampton Roads April, 1907, and raised October 1, 1907. The test paints were damaged and much of the fouling removed by passing chains under the barge to raise it. The test sections were 8 feet long and extended from the load waterline to the turn of the bilge on both sides. The results were:

Sec. Formulæ	Condition Jan. 18, 1907	Condition Oct. 3, 1907
(1) No. 3 A. C. and No. 4 A. F.	Paint hard; slightly scaled. Many small barnacles and slight amount of grass.	Fair condition. Very small amount of rust. A moderate amount of small barnacles and scattered bunches of grass.
(2) Commercial brand A. C. and A. F.	Covered with small barnacles and short grass. Paint off in some spots.	Very bad condition. Dense growth of small barnacles, clams and worms. Practically no grass. Considerable rust.
(3) No. 14 A. C. and No. 4 A. F.	Few barnacles and small amount of grass. Paint hard but scaling at water line.	Conditions much better than on section 2. The anti-corrosive better than that on section 1. About equal to section 1 as to fouling.
(4) No. 15 A. C. and No. 4 A. F.	No grass. Very few barnacles. Paint hard and in good condition.	Same conditions as on section 3.
(5) No. 16 A. C. and No. 4 A. F.	Approximately same condition as and slightly better than, section 4.	Conditions similar but slightly superior to conditions on sections 3 and 4.
(6) No. 17 A. C. and No. 4 A. F.	Few barnacles. No grass. Paint in excellent condition.	Conditions very similar to conditions on sections 3, 4 and 5.
(7) No. 3 A. C. and No. 4 A. F. (Same as sec. 1)	Condition approximately same as section 1, but slightly worse as to scaling.	No report.

The order of merit on January 18, 1907, was sections 2, 7, 1, 3, 4, 5 and 6; section 2 being the worst condition and 6 the best condition.

Coal barge Number 74 was painted October 1, 1906, and was examined February 21, 1907, and October 3, 1907. The bottom was sectioned similarly to the bottom of coal barge Number 69 described above. During most of the period of test the barge was moored at the Norfolk Navy Yard. It was used in raising coal barge Number 69 when the experimental paints were more or less damaged by chains. The conditions were:

Sec. Formulæ	Condition Feb. 21, 1907	Condition Oct. 3, 1907
(1) Commercial brand A. C. and A. F.	Paint scaling. Almost covered with small barnacles, some grass and much slime.	Most of paint disappeared. General corrosion and pitting. Dense growth of grass with scattered barnacles.

Sec. Formulæ	Condition Jan. 18, 1907	Oct. 3, 1907
(2) No. 14 A. C. and No. 19 A. F. (with bitter aloes added to A. F.)	No scaling below water line. No rust. Many small barnacles but not so many as on section 1. Film hard. Scaling at water line.	Paint hard. Very good anti-corrosive paint. Anti-fouling in fair condition. Much better than on section 1.
(3) No. 15 A. C. and No. 19 A. F. (with arsenious acid added to A. F.)	Very slight scaling at water line and no scaling below water line. Less barnacles than on section 2. No grass. Film hard.	Paint hard. Very good anti-corrosive paint. The anti-fouling was not equal to that on section 2 but better than that on section 1.
(4) No. 16 A. C. and No. 19 A. F.	No scaling. Rust cones where paint had been scraped off (shell plate dented here showing collision had occurred). More barnacles than on section 3. No grass and but little slime.	Paint hard. The best of the anti-corrosive paint. Anti-fouling paint in fair condition; much better than that on section 1.
(5) No. 17 A. C. and No. 19 A. F.	Practically same condition as section 4.	Paint hard. Very good anti-corrosive paint. Anti-fouling paint in fair condition; much better than that on section 1.
(6) No. 3 A. C. and No. 4 A. F.	Considerable scaling. Rust cones where paints had been scraped off. Very few barnacles. No grass.	Condition of anti-corrosive paint is only fair, inferior to that on sections 2 and 5. Anti-fouling paint in fair condition much better than that on section 1.
(7) No. 18 A. C. and No. 19 A. F.	Considerable scaling. Numerous blisters. Fouling about same as sections 4 and 5.	Poor anti-corrosive but better than the commercial brand. Condition of anti-fouling paint fair; much better than that on section 1.

The best anti-corrosive paints (February 21, 1907) were Numbers 16 and 17; the most inefficient anti-corrosive was Number 18. The best anti-fouling paint (February 21, 1907) was Number 19 with arsenious acid added (section 2).

The Wreck of the Wiltshire

The English Federal steamer Wiltshire was recently stranded on the Great Barrier Island of New Zealand, Australia. During a severe storm while she was stranded, the vessel broke in half and disabled the wireless apparatus, but the crew was able to communicate with the shore by semaphore signalling, and after forty hours was brought ashore. The photograph shows the condition of the vessel after the crew was rescued.

Insulating Materials for Shipbuilding Purposes—II

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

MINERAL wool is fibrous material formed by blowing molten slag or rock into threads by means of a jet of steam or air. Other names are mineral cotton, slag wool, rock wool and silicate cotton. The product made from rock is the best.

Mineral Wool

Mineral wool made from slag contains a small amount of sulphur unless the molten slag has been specially desulphurized, and such wool should therefore not be used as packing around steelwork on shipboard or as a covering for steel pipes or other steel containers. Access of water to mineral wool containing sulphur may result in the formation of sulphuric acid, with attendant rapid corrosion of the steel.

One manufacturer liquifies silica bearing limestone rock at a temperature of 3,500 degrees F. and blows this liquid rock into fine threads by means of a steam blast. The threads on their way to a cooling chamber are passed through oil vapor, which makes them soft and pliable and removes the minute particles of stone dust. The product looks much like cotton linters. A cubic foot of this rock fiber wool contains 8⅓ percent rock fiber and 91⅔ percent of entrapped air when packed to a weight of 14 pounds per cubic foot.

The chief field for mineral wool is the insulation of refrigerated cargo spaces. It is also of value for packing in between deck beams wherever the underside of a deck has to be insulated, as when the ship's cold storage rooms are over the machinery space.

Specifications for the material should require it to be of good quality, reasonably free from shot and other deleterious matter. Small globules of glass or stone not properly blown into threads are called shot.

Hair Felt

This material is felted cattle hair. It has high insulating properties and is considerably used for covering ammonia and brine pipes. It can be obtained in rolls in thicknesses from ¼ inch to 2 inches, and can be built up on the pipes.

Specifications should call for the best commercial grade used for pipe-covering insulating purposes.

A sectional covering is available suitable for cold water piping to keep the water cold and also to guard against condensation on the pipes. It is made up in standard sections, molded and compressed over a lining of waterproof paper. It is canvas jacketed and fitted with bands for fastening. A thickness of ¾ inch will answer for this service.

There are special coverings made of hair felt and other materials, some of which are very efficient.

Wool Felt

This is made up as a pipe covering in the same manner as hair felt, and the same remarks apply. The covering for hot pipes has been referred to. For cold pipes it has an inner lining of waterproof saturated felt.

In some cases the plain wool felt covering has all surfaces coated with a waterproof preparation, so that moisture will not get to the wool felt.

A more waterproof type of covering is made of alternate layers of wool felt and waterproof paraffin paper with an inner lining of paraffin paper.

There are also special combinations of wool felt and other materials in layers.

Vegetable Fiber Products

Some of these products have been found to fulfill shipboard requirements as refrigerating insulation. As stated under the head of heat retaining insulation, any of them which may be presented for consideration can be readily examined for everything except durability and the character of the ingredients is a good guide to that.

One of these products is waterproof lith, which is composed of 40 percent by volume of flax fibers, 58 percent of the limestone rock wool referred to under the head of mineral wool, and 2 percent of a waterproofing compound. It comes in boards 18 inches by 48 inches, from ½ inch to 3 inches thick. It weighs about 1⅓ pounds per square foot 1 inch thick and 3½ pounds 3 inches thick. It is a substitute for corkboard in service for which corkboard is the standard material.

The above product is also made up into sectional covering for pipes and fittings, using the same materials but specially selected and made somewhat more dense. The surfaces are coated with a waterproof compound. The thicknesses for the different services are the same as given under the head of cork pipe covering except that the ice water covering averages 1¾ inches thick.

Another product, linofelt, has been explained under the head of heat retaining insulation. Its particular field is small refrigerated rooms and ice boxes.

The nature of insulating paper has also been explained under the head of heat retaining insulation. Its principal value in refrigerating insulation work is to prevent losses due to joints in the main insulating materials.

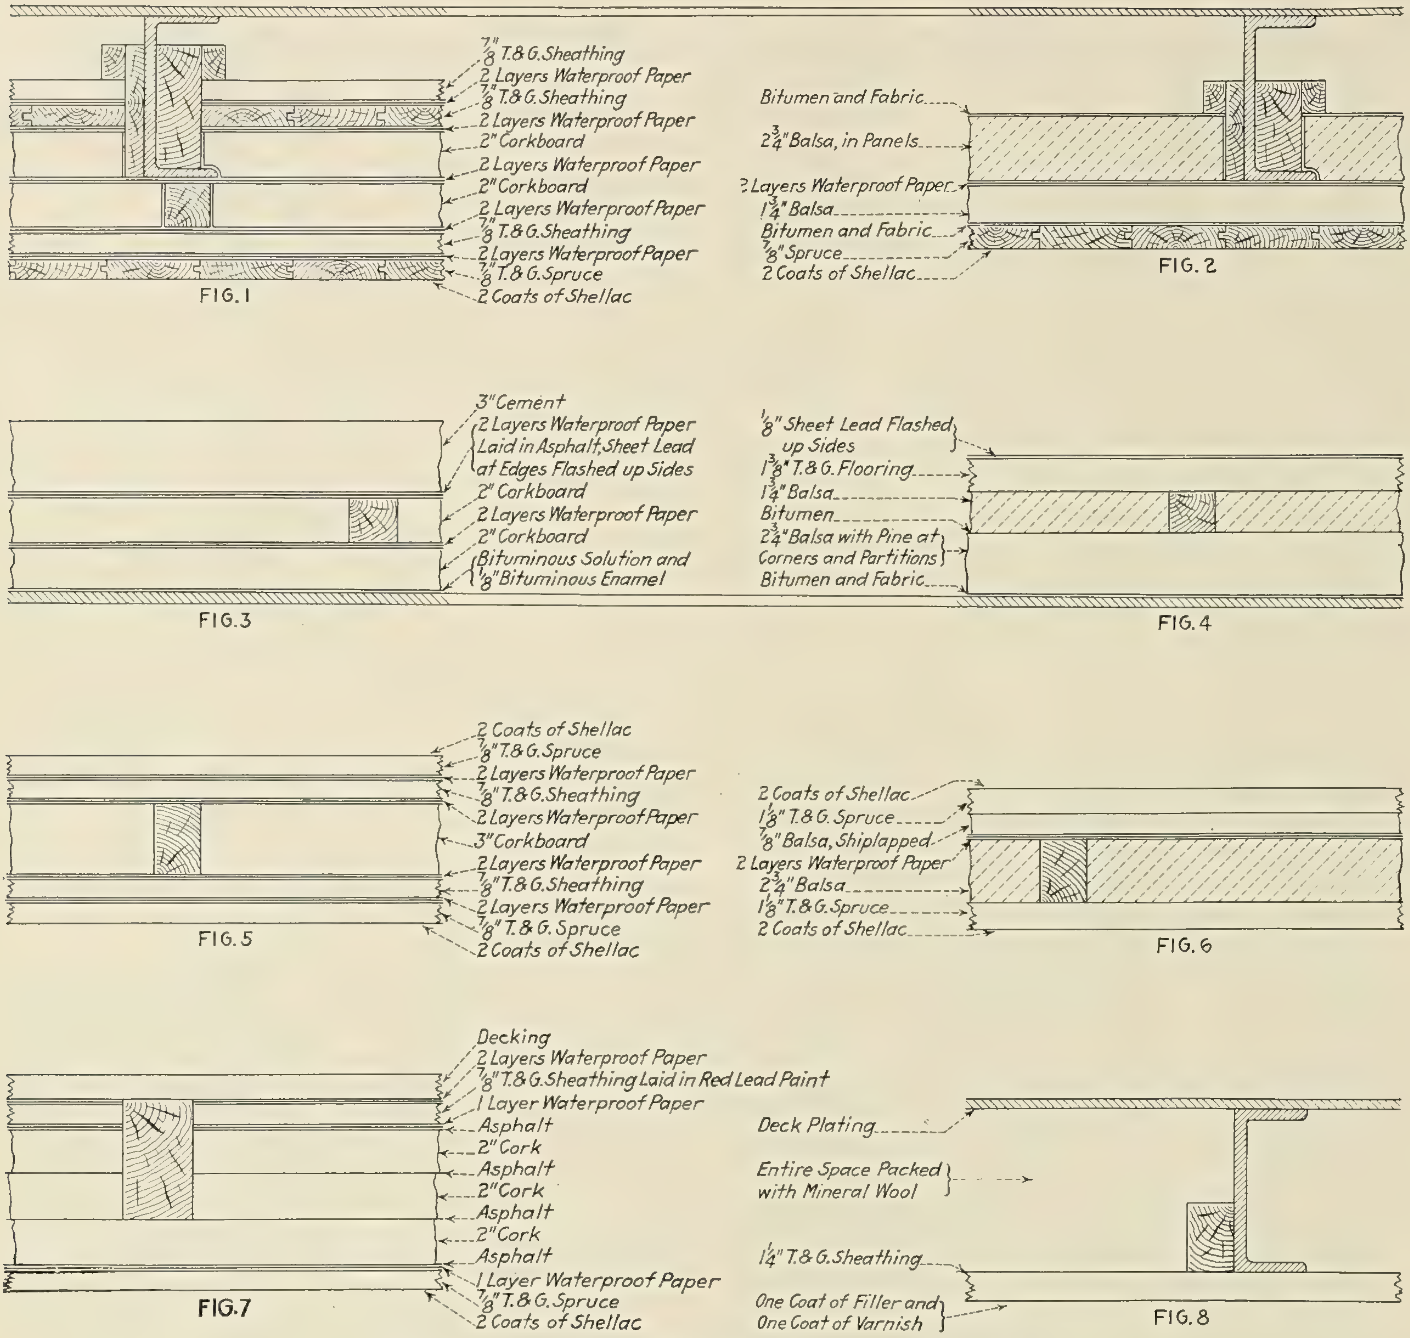
Method of Use

The accompanying illustrations give a general idea of the way refrigerated spaces are insulated on shipboard. Figs. 1 to 7 show typical installations for meat and vegetable rooms, the former being generally kept at a temperature of 20 degrees F. and the latter at 40 degrees F. Fig. 8 shows a typical installation in the cargo space of a refrigerated ship.

Figs. 1 and 2 represent either the under side of the deck or the side of a steel ship and afford a comparison in the construction with corkboard and with Balsa wood. The saving in wood sheathing with the latter is very apparent. The stiffener side of steel bulkheads calls for the same general layout except that when the stiffeners are angles it is usually better to run the corkboard or other insulating material entirely clear of the stiffeners.

Figs. 3 and 4 represent the insulation on a steel deck and also afford a comparison between the corkboard and Balsa wood constructions. The top coverings could of course be the same in each case and might differ from either of those shown. A cement covering on top of the Balsa wood in place of the wood flooring calls for the use of waterproof paper as shown for the corkboard insulation.

* Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.



Methods of Insulating Refrigerated Spaces on Board Ship

Figs. 5 and 6 represent partition bulkheads.

Fig. 7 represents corkboard insulation as applied to the under side of a wood deck, the beams being of such size as to make this method work out to better advantage than a layout similar to that of Fig. 1. The bitumen between the layers of corkboard is recommended by the corkboard manufacturers in preference to the waterproof paper. It is mopped on hot.

Fig. 8 represents the construction where mineral wool is used. The wood grounds are fastened to the frames or beams at the necessary distance from the plating to allow of the thickness of insulation called for, in some cases extending beyond the framing and making a packing space greater than the depth of the framing. A typical schedule covering the principal items of refrigerating insulation for the cargo spaces of a frozen meat carrying steamer, where mineral wool is used and where the temperature has to be maintained at not over 15 degrees F. under tropical conditions is—

Ship's sides	12 inches of mineral wool.
Underside of weather deck	10 inches of mineral wool.
Underside of second deck	8 inches of mineral wool.

Tank tops	6 inches of cork in two layers.
Machinery space bulkheads	11 inches of mineral wool.
Intermediate bulkheads	4 inches of mineral wool on the smooth side; the depth of the stiffeners on the stiffener side.
Shaft tunnel	10 inches of mineral wool.

In cases where the insulation under a deck is in the machinery space it is desirable to apply 2 inches of 85 percent magnesia or equivalent insulation below the wood sheathing, with an outer facing of thin galvanized iron.

Waterproof lith of the necessary thickness may be substituted for corkboard in the illustrations, and its manufacturers recommend a heavy bitumen coating mopped on hot between layers of this material rather than waterproof paper, although approving the paper as a substitute for the bitumen between the lith and wood sheathing.

Miscellaneous Heat Resisting Insulation

Insulation that is of value to retain heat is naturally of value to exclude it, so that a consideration of miscellaneous heat resisting insulation resolves itself mainly into pointing out which of the materials heretofore dealt with can be used

to advantage for such service. They will therefore be referred to under the head of some of the more important services of this character.

Underside of Wood Decks Over Boilers

The nature and extent of the insulation depends upon the closeness of the woodwork to the boilers and the air circulation in way of it. A typical installation for severe conditions consists of 1½ inches of 85 percent magnesia blocks set 2 inches clear of the wood and protected and secured in place by light galvanized iron. Other non-combustible insulation equivalent to the 85 percent magnesia could be used.

Inside of Engine and Boiler Casings

The protection in way of the stack might be as specified above for decks over boilers, with reduced thickness at the ends of the casings. Two-inch corkboard is used in some cases.

A good insulation for casings that are pretty well ventilated consists of 1 inch thick asbestos paper air cell blocks covered with galvanized sheet iron. The fastenings are run through 1 inch thimbles to prevent crushing the insulating material and the heads of the fastenings are completely soldered over.

Living Rooms Near Heated Spaces

The floors of staterooms or other accommodations over boiler rooms or galleys on steel ships can be protected in the manner illustrated by Figs. 3 and 4 for refrigerated rooms. A single layer of 1-inch cork will usually be sufficient, laid in bituminous solution and enamel as shown, with two layers of insulating paper and the required wood or composition deck covering on top. As stated in the article on "Deck Coverings"* the latter covering cannot be successfully used on steel decks which are exposed to excessive heat without some protection from that heat.

Joinerwork of accommodations in way of engine and boiler casings or galleys can be insulated by any of the good vegetable fiber products that are sufficiently fireproof as well as the materials which are primarily intended for more severe service.

Protection in Way of Stove Pipes, Stoves, Radiators, etc.

Asbestos millboard is the usual material for such service and it is usually necessary to protect it from damage by a covering of sheet metal. A thickness of 1/16 inch is sufficient.

Engineer's Consumable Stores

It is customary to have in the engineer's consumable stores a small supply of some of the insulating materials used on board of the ship together with the other materials necessary for their proper installation. The latter have been referred to under the head of some of the coverings and those references should be understood generally to apply to substitute coverings of like nature. Such a supply for the usual run of cargo steamships would be about as follows:

Fire bricks, assorted sizes as required	About 200.
Fire clay or high temperature cement	200 pounds.
Poultry wire, iron, 2-inch mesh, No. 14 B.W.G., annealed	10 pounds.
Asbestos plaster, two bags	100 pounds.
Asbestos cement, hard finish, one bag	50 pounds.
Asbestos millboard, 40-inch by 40-inch by ¼-inch thick	4 sheets.
8-ounce canvas for pipe covering	10 square yards.
Unbleached muslin for pipe covering, 2½ square yards per pound	25 square yards.
Cotton twine for pipe covering, No. 6, 1,000 yards per pound	one ½-pound ball.
Smooth-on	5 pounds.

*See Marine Engineering and Shipping Age, March and April, 1922.

Table I—Thermal Conductivities of Various Insulating and Building Materials

All the figures given below, with the exception of the first two, are the results of measurements made at the Bureau of Standards, Washington, D. C., on representative samples of materials. They represent actual internal conductivities, surface effects having been eliminated. The mean temperature of the determination was about 77 degrees F., and the temperature differences used varied from 50 to 77 degrees F.

K is the thermal conductivity in B.T.U. per square foot per inch of thickness per degree F. difference in temperature per 24 hours.

Material	Description	K	Pounds Per Cubic Ft.
Vacuum	Silvered vacuum jacket—residual air about 0.001 m.m. Hg	0.1	...
Air	Ideal air space—if radiation or convection could be prevented	4.2	0.08
Calorox	Fluffy finely divided mineral matter	5.3	4.0
Kapok	Imported vegetable fibre—loosely packed	5.7	0.88
Pure wool		5.9	6.9
Pure wool		5.9	6.3
Hair felt		5.9	17.0
Pure wool		6.3	5.0
Keystone hair	Hair felt confined with building paper—flexible	6.5	19.0
Mineral wool	Loosely packed	6.3	12.0
Mineral wool	Medium packed	6.6	12.5
Corkboard	No artificial binder—low density	6.7	6.9
Mineral wool	Felted in blocks	6.9	18.0
Cotton wool	Loosely packed	7.0	...
Pure wool		7.0	2.5
Insulite	Pressed wood pulp—rigid	7.1	11.9
Mineral wool	Firmly packed	7.1	21.0
Linofelt	Vegetable fibre confined with paper—flexible and soft	7.2	11.3
Ground cork	Ordinary	7.1	9.4
Corkboard	No artificial binder—high density	7.4	11.3
Celite	Diatomaceous earth powder	7.4	10.6
Granulated cork	About 3-16 inch	7.5	8.1
Balsa wood	Very light wood untreated — across grain	7.5	7.1
Balsa wood	Same sample with 13 percent waterproofing compounds	8.3	8.0
Cotton seed hull fiber	Loosely packed	7.5	4.4
Cabot's quilt	Eel grass enclosed in burlap	7.7	16.0
Flaxlinum	Felted vegetable fibres — firm and flexible	7.9	11.3
Fibrofelt	Felted vegetable fibres — firm and flexible	7.9	11.3
Rock cork	Mineral wool and binder—rigid	7.9	16.0
Ceiba wood	Untreated—across grain	7.9	7.1
Balsa wood	Light wood—untreated	8.3	7.4
Corkboard	Bituminous binder	8.4	16.0
Wood felt	Flexible paper stock	8.7	21.0
Lith board	Mineral wool vegetable fibres and binder—rigid (different somewhat from waterproof lith)	9.1	12.5
Balsa wood	Medium weight wood	9.2	8.9
Planer shavings	Various	10.0	8.8
Wall board	Stiff pasteboard	11.0	...
Air cell ½ in.	Corrugated asbestos paper enclosing air spaces	11.0	8.8
Air cell 1 in.	Corrugated asbestos paper enclosing air spaces	12.0	8.8
Asbestos paper	Asbestos and organic binder	12.0	31.0
Zenitherm	Diatomaceous earth and asbestos—rigid	11.8	16.0
85% magnesia	Magnesia and asbestos—rigid	12.2	19.0
Insulex	Asbestos and plaster blocks—very porous	13.5	18.0
Diatomaceous earth	Natural blocks	14.0	43.0
Balsa wood	Heavy wood	14.0	20.0
Fire felt sheet	Asbestos sheet coated with cement—rigid	14.0	26.0
Fire felt roll	Soft, flexible asbestos sheet	15.0	43.0
Cypress	Across grain	16.0	29.0
Fullers earth	Argillaceous powder	17.0	33.0
Asphalt roofing	Felt saturated with asphalt	17.0	55.0
White pine	Across grain	19.0	32.0
Asbestos millboard	Pressed asbestos—not very flexible	20.0	61.0
Mahogany	Across grain	22.0	34.0
Insulex	Asbestos and plaster blocks—porous	22.0	29.0
Virginia pine	Across grain	23.0	34.0
Oak	Across grain	24.0	38.0
Hard maple	Across grain	27.0	44.0
Parafine	"Parowax" melting point 52°C	38.0	56.0
Gypsum plaster		54.0	...
Asbestos wood	Asbestos and cement—very hard and rigid	65.0	123.0

Sound Proof Insulation

Sound waves upon reaching any material are either reflected, transmitted through it or absorbed. That material forms the best sound proof insulation which while possessing the necessary durability, ease of application and other qualities will absorb most of the sound.

The principal material used for sound proof insulation on shipboard is hair felt and the following extracts from Navy Department Specifications for sound proof lagging illustrate an approved method of its application:

This shall consist of hair felt in four layers, each layer 1 inch thick and weighing not less than 14 ounces per square foot, fitted between furring pieces and held in place by steel sheathing, which shall be secured to wood furring pieces. For large vessels

(a) Same authority as for the B. T. U.

the sheathing shall be of 2½-pound plating except that for the floor shall be of 5-pound plating. For torpedoboat destroyers and other vessels of special light construction the sheathing shall be 17 mils thick except that for the floor shall be 2½-pound plating.

The spaces between the floor sheathing and the deck shall be filled with hair felt where the compartment is in the interior of the vessel or asbestos where the compartment has direct communication with a weather deck. The thickness of the floor insulation shall be suitably reduced where the deck height clear under beams (not taking account of the insulation) is less than 7 feet, with a minimum thickness of hair felt or asbestos of 1 inch.

For best results the lagging should cover as much as possible of all surfaces in the compartment which is to be soundproofed and should be fitted to full thickness over beams, stiffeners, etc.

A number of the vegetable fiber insulating materials previously dealt with have good sound insulating value and are advocated by their manufacturers for this purpose. Linofelt, Flaxlinum and Cabots Quilt are among them.

Mineral wool is used in some cases but the probability of its pulverizing, settling and leaving empty spaces is a decided objection to it.

The particular field of sound proof insulation on shipboard is the radio apparatus room. There are times when it is desirable to specially insulate some of the accommodations. Telephone booths and voice tube booths are sometimes insulated.

Electrical Insulation

The chief concern of the shipowner and shipbuilder apart from the wisdom of having this important insulation in line with the best practice is to see that it complies with the requirements of the National Board of Fire Underwriters and

the Rules and Regulations of the United States Steamboat Inspection Service, and, where a vessel is classed, with the requirements of the classification society concerned.

The United States Steamboat Inspection Service requires that—

Wires shall be run in approved iron conduits, armored casing or molding.

Iron conduit or armored casing shall be required in bunkers, cargo spaces, storerooms, etc., and in all places where the leads are liable to mechanical injury. Joints in wiring shall be avoided as far as possible in the above-named spaces. Where wires are led through beams, frames, or non-watertight bulkheads, they shall be carried either in iron conduits, armored casing or protected by hard rubber or other equivalent bushings.

Where wires are carried through watertight decks or bulkheads, they shall be provided with a suitable stuffing box at the deck or bulkhead. Where such points are liable to mechanical injury they shall be protected by suitable boxes or cages.

Joints shall be so spliced or the parts so joined as to be both mechanically and electrically secure without solder. They shall then be soldered and properly insulated and further protected by waterproof tape.

Also that the electrical installation including the wiring carried through wooden bulkheads, etc., shall be of such a nature as to preclude any danger from fire.

Rubber and porcelain are the two principal materials used for electrical insulation, the former to cover the conductors and the latter to insulate them from other materials to which they are attached or through which they pass. Hard rubber is also used for the last mentioned service.

Wiring which passes through bulkheads made of combustible material should be insulated from them by running them through tubes of porcelain, or other insulating material.

Insulation containing rubber is damaged by oil and particular attention has therefore to be given to the covering of electrical conductors on oil tankers. Particular attention should also be given to the insulation of wiring in locations where moisture is liable to collect. In both cases the wiring should preferably be lead covered.

Large Cranes for Shipyards and Harbor Service

Construction and Operation of 250-Ton Hammerhead and Floating Cranes Built in Germany for Fitting Out Large Ships

By E. Krahnen, M. E.*

In the so-called hammerhead cranes, the first of which was built by the Benrath Company (now Demag, Duisburg) a double cantilever is connected to a structural steel post which forms the central axis of a pyramidical frame work. The mechanism for lifting the load and for traversing the trolley are arranged entirely upon the trolley which travels on the front part of the cantilever, the tail end forming the balancing arm.

In later designs the lifting and traversing gears were usually arranged on the balancing arm, so as to minimize the weight of trolley and jib, the weight of the machinery acting as a counterweight. Also the form of the tower underwent a complete change. It now consists of a structural steel pyramidical column over which fits a frame-work to the head of which is fixed the cantilever.

The whole weight of the cantilever as well as the bell structure rests on the top of this central column and thus adds to the stability of the crane. The forces are transmitted to the column, the base of which is comparatively small. To reduce the friction to a minimum a combined roller and center bearing is placed on the top of the column while the lower extremity of the bell structure bears against a pressure ring.

Provisions are made to facilitate the inspection of the top bearing. By means of four hydraulic jacks the entire superstructure of the crane including the bell structure can be lifted without any preparations whatsoever and of a sufficient height to free the rollers and allow of removing any part of the bearing.

Auxiliary Slewing Jib

While the size and lifting capacity of these cranes could be increased in later designs it was not possible to increase the slewing speed of the jib on account of the enormous masses that had to be accelerated. This made these cranes rather unwieldly for handling smaller loads, up to about 20 tons, which form the bulk of the material to be lifted while the maximum loads have to be lifted only occasionally. To facilitate the handling of lighter loads, the Demag, Duisburg, introduced an auxiliary slewing jib crane of about 20 tons capacity that travels on a track laid on the upper flanges along the entire length of the cantilever. The main crab travels on a runway that is placed between the main girders. The jib crane is able to cover a fairly large area on both sides of the crane and permits of masts higher than the crane itself being placed in position.

An objection to the ordinary type of hammerhead crane is that the cantilever arm in rotating may foul the masts of vessels which are being fitted out. This has been overcome by fitting a derricking motion to the jib, Fig. 2, making the crane independent of the height of the deck superstructures because when the jib is derricked the crane revolves clear. As the crane shown in Fig. 1, built for the Blohm & Voss shipyard, Hamburg, embodies all these features a short description of it will be given.

Blohm & Voss 250-Ton Crane

In the design of this crane great care was taken to reduce the deadweight to the utmost so that the crane could be worked with the least power possible. Owing to the great many ways the load may be applied in addition to the numerous motions that had to be performed the calculations were of a most elaborate nature. The whole crane, and especially the jib was built to offer the least possible resistance to wind pressure.

The crane is capable of lifting a load of 250 tons at a radius of 113 feet; 200 tons at 130 feet; and 100 tons at 175 feet. The electric locomotive crane, that travels a distance of 300 feet on the top of the cantilever, is able to lift 20 tons at a radius of 33 feet, and 10 tons at 60 feet so that the total radius for a 10-ton load is not less than 240 feet.

Control

The whole machinery with exception of the slewing gear is arranged in a house placed in the tail end of the cantilever. Two Ward Leonard motor generating sets of 95 horsepower are provided. With this system of control the whole of the regulation is effected by varying the excitation of the generators, the motors being permanently excited. As the

*With Demag, Duisburg, Germany.

Fig. 1.—250-Ton Hammerhead Crane at Blohm and Voss Shipyard, Hamburg, Germany

circuit for exciting the field amounts to only 3 percent of the main circuit, very small controllers are required.

The position of the controller handle exactly corresponds to a given speed of the motors. As it can be easily moved through a fairly large angle, a most accurate graduation of speeds is obtained so that the slightest movements can be made with ease and exactness, particularly when fitting machines or engine parts.

For ordinary working purposes one set is used for lifting, the other for luffing. Provisions are made that both motors can be switched to one set so that the work may be continued in case one set should get out of order.

Hoisting Mechanism

The hoisting motors drive two friction drums round which the hoisting rope is wound as well as the luffing gear. The slack end of the rope is taken up by a compensating block moving vertically on the rear of the bell structure. By the use of a change-speed gear smaller loads can be lifted at a greater speed. Two brakes are fitted, one electro mechanical brake the other a mechanical brake which is worked by the operator and which might serve as an emergency brake.

The lifting speeds are 5.25 feet per minute for the full load of 250 tons; 6.5 feet for loads below 200 tons; and as much as 13 feet for loads below 100 tons. The lowering speeds are 50 percent higher.

For luffing the jib a pinion on the motor shaft is thrown in gear which drives through bevel and spur gear reductions two large horizontal spindles situated on the top of the cantilever. These spindles traverse a nut carriage that is connected to the top flanges of the main jib by means of connecting rods. The luffing gear is designed so that the jib can be raised in 30 minutes with no load, and within 40 to 50 minutes with a load of 110 tons.

To avoid overloading of the crane structure the controlling devices of the main trolley and the locomotive crane are electrically blocked so that only one crane can work at a time. The main trolley can thus be only operated while the jib crane is standing in its extreme position on the tail-end of the cantilever where it acts as additional counterweight.

One Man Operates Entire Crane

Only one man is required to operate the whole crane. From his cabin below the fulcrum of the jib he is able to observe the work. Indicating devices, that are placed in the cabin, show him the exact position of the load even if the load is out of sight.

The locomotive crane is a self-contained crane with its own controlling devices and a separate controller for operating the slewing gear of the main jib.

Cranes of these dimensions have a large working area which can be doubled by placing them on a pier so that ships on both sides of the pier can be fitted out. The working area, though considerably increased over that of the old type cranes, can naturally be only a limited one. An almost unlimited area can only be covered by using a floating crane as it can be moved along the ship wherever required, obviating the necessity of moving the vessel at its moorings.

Floating Cranes

Floating cranes were first built as shears placed on a pontoon. A new type was introduced by the Demag, Duisburg, who built this crane for Swan, Hunter & Wigham Richardson's shipyard. To increase the reach a bent jib was employed which allowed the crane to lie close to the ship. With the increasing size of ships, the jib had to be mounted on a pedestal or tower of sufficient height to enable the jib to clear the deck superstructures. A crane of this type was first built for the Russian government for its Baltic shipyard, and has been subsequently furnished

to the Société Anonyme des Forges et Chantiers de la Méditerrane la Seyne, Toulon, France, to the Thames Iron Works, London, to Wilton's Engineering Works Shipyards, Rotterdam, and to the Russian Shipbuilding Company of Nikolajeff. They were built for putting on board ship complete boilers, turbines, pivots for gun turrets and for armoring battleships and have given much satisfaction. The crane represented in Fig. 3 has a capacity of 200 tons. The pontoon is built of steel and angles and is about 100 feet long and 78 feet wide. It is divided into a number of watertight compartments by longitudinal and transverse bulkheads. The stability of the crane is maintained even if two adjacent compartments become filled with water.

On this pontoon is built a steel frame work tower about 36 feet high. The jib which is provided with a derricking motion is built on the top platform of this tower. It derricks round the front portion of its base on two trunnions. The rear legs of the jib are secured by connecting rods fixed to a travelling nut carriage which travels vertically against the rear face of the tower. This carriage is traversed by two large vertical screws which are made to revolve together, for actuating the crosshead by a 110 horsepower steam engine, placed on deck. The angle formed by the front face of the jib and the extension of the platform can be varied from 30 to 85 degrees, a range which corresponds to a travel of the jib head of about 35 feet. Two sets of 100-ton tackle blocks are provided and also a 5-ton runner and a 20-ton block fixed to the end of the jib.

For lifting a 200-ton load, an equalizer is placed between the two 100-ton hooks. The main hook is arranged to float on a ball bearing facilitating the revolving of the load if required. The hauling ropes are wound round two drums fitted on deck and driven simultaneously or separately at

Fig. 2.—250-Ton Hammerhead Crane With Raised Jib

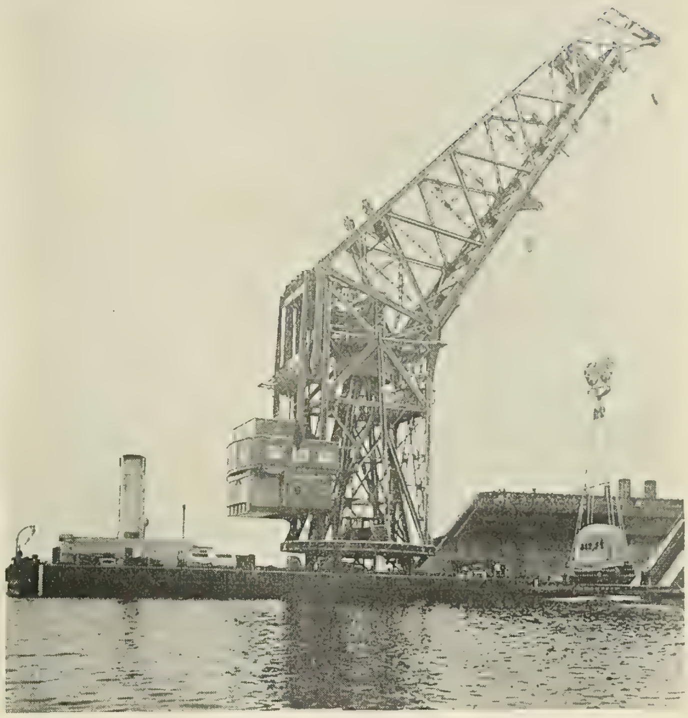

Fig. 3.—Floating Crane Handling 312-Ton Test Load

will by a 110 horsepower engine similar to the one for extending and pulling up the jib.

The 5-ton runner which travels along the front beams of the jib can be made to occupy any position along the jib.

The pontoon is provided with a compartment for taking water ballast with the object of limiting the inclination of the crane when heavy loads have to be lifted. Two steam winches are used for towing purposes.

A still later floating crane developed by the Demag is electrically operated, the jib being mounted on a bell shaped structure capable of revolving through 360 degrees on a tall pyramidical steel tower.

The full working load of 250 tons can be lifted to a height of 180 feet above the water level with an outreach beyond the pontoon fender of not less than 60 feet. With any load up to 50 tons the height of lift is 150 feet at an outreach of 138 feet, beyond the pontoon. Dealing with normal lifts, excepting turbines and boilers, this crane may lie on the offside of the ship, lift a load from the wharf, the jib reaching over the ship, and deposit it in the ship at any point desired.

For lifting there are two 95 horsepower motors with series parallel control. These motors are utilized for rotating the two large screws used in luffing the jib. As the luffing and hoisting gear may be coupled together, it is possible to move the load approximately horizontal while derricking.

The electric current for these motors is generated by two turbo-generators on board the pontoon so that the crane can be used at any point in the yard and is independent of a land electric station. Only one man is required to operate the crane.

In this crane there are no movable counterweights, nor is water ballast employed. The necessary stability with all loads and all positions of the jib depends wholly on the dimensions of the pontoon. This allows the operator to fix his attention entirely on the handling of the load, eliminating the possibility of capsizing through neglecting to tend to movable counterweights.

The pontoon is propelled by twin screws driven by steam engines each of 500 horsepower. A small electric lighting plant is installed on board which makes working at night possible by the aid of powerful searchlights.

Further Experiments on Contrary-Turning Co-Axial Screw Propellers*

By General G. Rota†

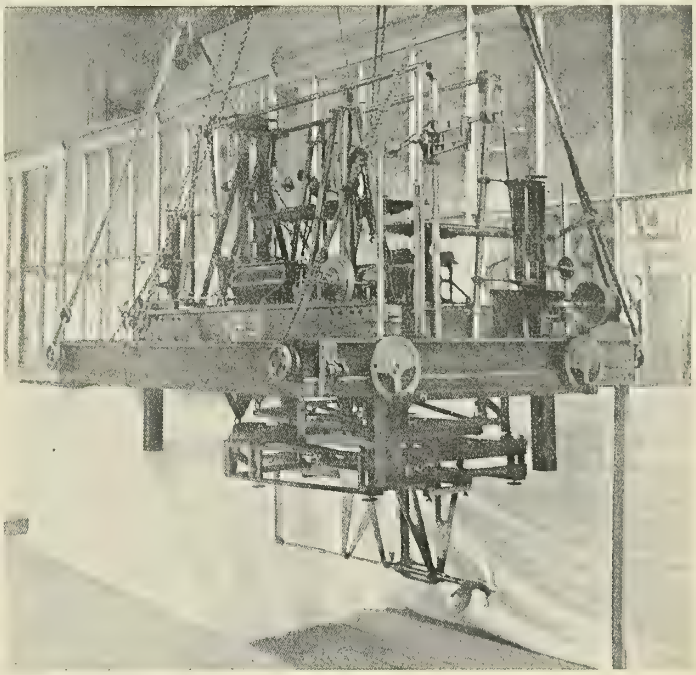
SHIP propulsion by means of double co-axial contrary-turning screw propellers has long been a matter of research. More than once results of experimental work have been presented before this Institution, and have given rise to interesting discussions.

In 1909 I had the honor of submitting the results of some experiments made in the Royal Dockyard of Castellamare di Stabia on a steam launch, whose single propeller had been replaced by two co-axial contrary-turning screw propellers. The same steam engine which drove the single propeller was employed to drive by gears the double propellers. The experiments showed that practically the same speed was obtained in both systems, with the same indicated horsepower, so that the work lost in the gear transmission was evidently regained through a better efficiency in the propellers. I rated this gain to be about 20 percent but whatever be the real amount of this figure, one thing came out as stated, viz. that the total efficiency of double contrary-turning screw propellers was higher than that obtained by a single propeller. Still better results could be obtained, as compared with ordinary twin screws, if the gain due to the lesser resistance of the hull, and to the absence of brackets, shafts and bossings, had been taken into consideration.

Mr. Luke, in his interesting paper presented to this Institution in 1914,†† brought a valuable contribution to this question, pointing out the value of hull efficiency elements under various conditions, viz. with a single screw, with twin screw propellers on parallel axes, with double contrary-turning co-axial screw propellers (combination), with double co-axial similar-turning screw propellers (tandem), etc. Considering the arrangement of propellers in which I am now interested, viz. with contrary-turning co-axial propellers, the particulars of Mr. Luke's experiences pointed to the conclusion that if a real gain in hull efficiency was obtained in full-bodied ships, but less in fine-formed ships, on the other hand, the propulsive efficiency proper for the screw was far less than that obtained with the single screw or ordinary twin screws, in the ratio of about 86 percent; so that there was practically the same total propulsive efficiency with fine-formed ships, and superior only by 7 percent with the co-axial contrary-turning screw propellers associated with full-bodied ships as compared with the single screw. These results did not agree with the results I obtained from my first experiments, and this induced me to undertake new experimental researches into this question.

In my first experiments with screw models, which I reported briefly in a written discussion on Mr. Luke's paper above mentioned (and I am inclined to think in those also of Mr. Luke and of other experimenters), the propulsive figures of each of the two contrary-turning co-axial screw propellers were not measured separately, so that it was always the value of the thrust given by the two screws and the total value of the efficiency of both which were obtained.

Wishing to know exactly what are in every case the peculiarities of the efficiency of each of the two screws acting together while contrary-turning, we have succeeded in the Experimental Tank at Spezia in modifying the general arrangement of the apparatus for the experiments with model screws, so that we can now measure the thrust and turning force of each screw either separately or in combination. It is not possible here to give a description of that apparatus, but it is shown in the photograph.



Apparatus Used at Spezia Tank for Testing Model Contrary-Turning Co-Axial Screw Propellers

The analysis of the performances of each screw enables us to investigate the influence of diameter, pitch-ratio, disk-area ratio and revolutions of the same, with the object of obtaining a higher efficiency, because, as is well known, this can only be attained by experiment.

In this paper, therefore, I give the results of some researches made with that apparatus with the sole object of adding a small contribution towards the solution of model experiment problems.

*Paper read at the Paris summer meetings of the sixty-third session of the Institution of Naval Architects, July 6, 1922.

"BEHIND" EXPERIMENTS (I.E. SCREW REVOLVING BEHIND THE MODEL)

		Full Model				Fine Model			
Screws in Action	Propeller Efficiency, E	Wake, $\frac{v - v_1}{v_1}$	Thrust Deduction $1 - \frac{R}{S}$	Hull Efficiency, $e = \frac{v}{v_1} . \frac{R}{S}$	Propulsive Efficiency, $E . e$	Wake	Thrust Deduction	Hull Efficiency	Propulsive Efficiency
Single	0.56	0.34	0.17	1.11	0 62	0.22	0.16	1.02	0.57
Double ordinary	0.56	0.20	0.15	1.02	0.57	0.13	0.13	0.98	0.55
Double contrary-turning co-axial	0.49	0.61	0.17	1.34	0.66	0.33	0.12	1.17	0.57

Several sets of experiments were carried out with this apparatus, adopting different kinds of screws, and I shall describe the principal features of some of them. Symmetrical screws (type A) of 250 millimeters diameter, 325 millimeters pitch, and a disk-area ratio of 20 percent, have given results which almost agree with those given by Mr. Luke.

In Fig. 1 are given the thrust, turning-force and efficiency curves as obtained with these co-axial screws. The difference between the two efficiency curves is considerable. The one corresponding to the fore propeller is much below the efficiency curve of the after propeller.

In Fig. 2 are given the thrust, turning-force and efficiency curves resulting from experiments with the same propellers (A) fitted on parallel shafts as in the ordinary twin-screw arrangement; the same are compared with the thrust turning-force and efficiency curves relating to contrary-turning screws on a common axis; the thrust and turning-force being the sum of the same relating to the individual propeller, and the efficiency is the total efficiency of the propelling system. From this comparison it appears that co-axial screw propeller efficiency for the model A is inferior to that of the single screw or the twin screws of same shape acting on parallel axes to an extent which agrees sufficiently with Mr. Luke's deductions; the efficiency of the double co-axial, for the case considered, being about 88 percent as compared with the same value for the ordinary twin-screw arrangement. With other combinations of screw propellers, however, the results were very different, so that it is possible not only to have a higher value of the ratio mentioned above, but also to have practically equal efficiency.

Further experiments were made with other screw propeller arrangements to investigate the influence of a less diameter for the fore propeller than for the after one and vice versa, keeping a constant pitch and increasing the disk-area ratio as compared with the experiments previously mentioned. In a first combination (see Figs. 3 and 4), the fore propeller (B) had

diameter = 210 millimeters
pitch = 325 millimeters
disk-area ratio = 0.40

and the aft propeller (C) had

diameter = 250 millimeters
pitch = 325 millimeters
disk-area ratio = 0.40

In a second combination the propellers were interchanged (see Figs. 5 and 6). The results were very interesting; the total efficiency of the co-axial screw propellers was practically the same in both combinations, and may also be considered to be the same as with equal open single or double ordinary screw propellers.

Total Propulsive Efficiency Increased

In view of the previous considerations, a good screw propeller efficiency can be obtained either with the two co-axial contrary-turning screws or with the single or with ordinary twin screws; so that the total propulsive efficiency, which, as is well known, is the product of screw propeller efficiency multiplied by hull efficiency, for the double contrary-turning screw propellers will have all the beneficial influence of the high hull efficiency of the same combination compared with the corresponding figure for single and ordinary twin-screw arrangements, as was stated in the interesting communication made by Mr. Luke.

Mr. Luke's investigations showed in fact that with the double contrary-turning screw propellers on a common axis the hull efficiency was 1.34 to 1.17, according to the fineness of the hull, instead of 1.02 to 0.98 as in ordinary twin-screw arrangements, and in the same ratio in the whole will remain at least the corresponding value of total propulsive efficiency. I am inclined to think that by the use of double contrary-turning screw propellers, and with the arrangements which experience may suggest, one will obtain a great improvement in the total propulsive efficiency—not less than 20 percent—even without taking into account the gain which may easily be foreseen by reason of the reduced resistance of the hull itself as a consequence of the suppression of brackets, bossings, etc.

Other special devices to increase the ship propulsion efficiency are already in use: the well-known fixed guide-blades used in Sir John Thornycroft's screw turbine propellers were shaped with a contrary curvature, as compared with revolving screw blades, so as to direct the water into a straight line aft and thus utilize the rotational component of the wake. Herr Wagner's counter-propeller is a similar contrivance designed to direct in a straight line aft the helicoidal motion of the wake. These experiments, and also the applications made with those devices, have shown, in various degrees, the possibility of increasing a ship's propulsive efficiency, but I am not aware of any advantage having been gained by adopting any of the above devices in order to improve the total efficiency, viz. screw efficiency and hull efficiency.

The double contrary-turning co-axial screw propellers would give, in my opinion, still better results, considering the contribution offered to the whole thrust by fixed guideblades or a fixed counter-propeller in a second propeller.

The arrangement of double co-axial contrary-turning screw propellers should therefore be considered with great attention by designers in cases where the difficulties connected with the arrangement of two co-axial shafts do not appear impossible of solution. Such a case is that of cargo boats with very full hulls when the propelling machinery is far aft. There is also a possibility of utilizing this system in submarines.

Machinery Arrangements

It is not possible here to enter into details of the alternative machinery arrangements in mercantile cargo boats, i.e. whether steam turbines should be utilized to drive both shafts, or a combination arrangement with a reciprocating steam-engine on the inner shaft and a steam turbine on the outer shaft, or whether electric motors should be provided on both shafts.

Other arrangements could be devised with steam turbines and reduction gears.

The double contrary-turning co-axial screw propellers would be, perhaps, suitable in submersible craft with the object of obtaining the simultaneous motion of both motors, electric and Diesel, for eventually increasing the speed on the surface. The advantages should be considerable; for example, a submersible with electric motors able to give a speed of 9 knots submerged and with Diesel motors, 12 knots surface speed. If it were possible to have all the motors acting at the same time, by adopting the co-axial contrary-turning screw propeller system, the surface speed could probably be increased to 15 knots, and perhaps a little more.

Under ordinary circumstances only one screw is in action, the other revolves idle, and so increases the resistance as to require a higher thrust; but considering all aspects of the problem, it should be possible to ensure conditions such as to reduce and perhaps overcome the above difficulty.

Before concluding I desire to express my gratitude to Captain A. Farina, of the Royal Italian Naval Construction Corps, for his valuable assistance in conducting the experimental work in the Tank at Spezia, where he is now in charge.

Export Markets for Marine Engine.—An analysis of foreign markets by the Acting Chief of the Automotive Division, Department of Commerce, shows that Latin America offers excellent prospects for the sale of American motor boats and marine engines, while in the Far East a most remunerative market for motors can be developed.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

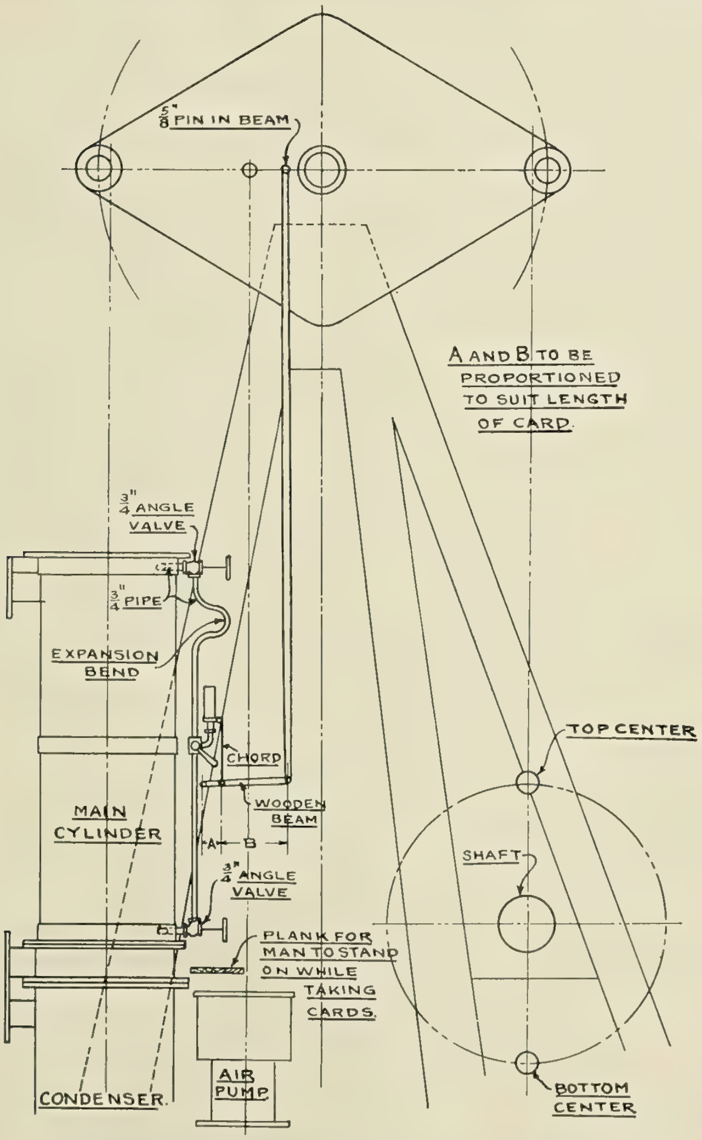
Indicator Cards from a Beam Engine

Q. (1164).—Please advise me how to connect a steam indicator to a beam engine for taking set of cards from same. The engine is on an inside wheel double end ferry steamer and has a cylinder 58 inches diameter and 10-foot stroke, the steam pressure allowed on the boiler is 50 pounds per square inch.

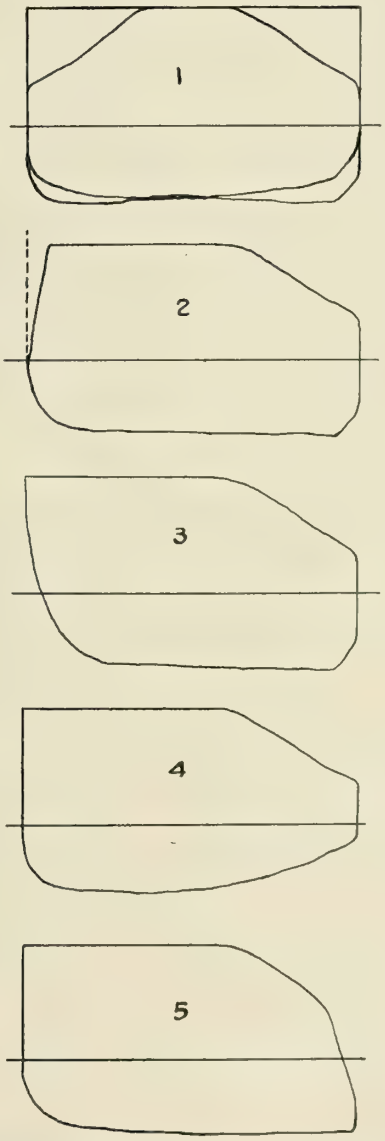
There are no connections on the cylinder, or any other part of engine, for connecting the indicator or cord of same. I can put the cocks in the cylinder, but I want to know where to connect the cord to the engine.

Please sketch set of cards, as they should look, taken from this engine, also sketch sets with too early and too late steam admissions and exhaust opening.

A. (1164).—If, as you say, there are no connections on the cylinder, it will be necessary before rigging up to indicate to have the upper and lower parts of the cylinder bored and tapped to take the usual piping for the indicator. These tappings should be drilled so that they open into the clearance between the top of the piston and under side of cylinder cover when the crank is on bottom center and the under side of piston and bottom of cylinder when the crank is on top center. This piping should be not less than ¾ inch and should have a valve top and bottom with the usual three-way cock to take the indicator, at some convenient place, preferably about halfway between the upper and lower connections.



Method of Taking Indicator Cards from Beam Engine



Sample Cards Taken from Beam Engine

In the upper part of this piping a bend should be made to take care of the expansion.

The reducing gear can be of any pattern. In a number of cases the writer has used a reducing gear along the following lines: A small pin about ⅝ inch diameter is located in the beam as near as possible to the beam center to suit conditions and from this pin a light link is run down to a small beam which can have its center fastened to any convenient stationary part of the engine. The engine frame is generally the best place for this purpose. This beam and link can be made of wood (ash will do) as wood is light and inexpensive. It will be necessary to arrange the leverage of the beam to get the required length of card.

Acknowledgment is herewith made to the W. & A. Fletcher Company, Hoboken, N. J., for the above reply to your question with its accompanying sketch.

Referring to the cards shown:

1. Valves properly set.
2. Late admission.
3. Early admission.
4. Late exhaust.
5. Early exhaust.

Comparison of Boilers

Q. (1166).—Will you please let me have some information regarding the efficiency, power developed, cost of installation and durability of Scotch marine, straight tube, bent tube, watertube and externally fired return tubular boilers such as are used in stationary plants, assuming similar conditions as nearly as possible in each case. Also similar information for coal and oil fuel.—F. V. G.

A. (1166).—From a careful reading of your question it would appear that a discussion in considerable detail of the power, cost of installation, durability, etc., of the several forms of Scotch boiler in comparison with the watertube and all other recognized forms of boiler would be necessary in order to properly answer your question. You will readily appreciate the fact that any such exhaustive handling of the subject is entirely without the province of this Department. It is believed that information, such as you desire, can only be obtained by a thorough study of boiler design and operation in each of the fields in which the several types referred to are in use. Even after such a study has been made, it is considered doubtful whether the comparison "assuming similar conditions as nearly as possible" would be practicable as each type is presumably fitted for operation under certain conditions and would be at disadvantage, if otherwise operated.

LETTERS TO THE EDITOR

Effective Simplification Must Consider Operator's Standpoint

I have read with interest the article by Mr. N. C. Wiley in the August issue of Marine Engineering and Shipping Age, "Simplification—Has it a Place in Shipbuilding?"

It is, of course, agreed that simplification with resultant saving in time and money to both owner and shipbuilder is desirable, if, by so doing, a satisfactory job is obtained from the owner's or operator's standpoint. Mr. Wiley's article treats the subject entirely from the shipbuilder's or contractor's standpoint and fails to appreciate the subject from the operator's point of view.

The author's criticism of operators who maintain a technical staff to prepare plans and specifications giving a detailed description of the work, as well as to check the plans and certain important details of construction, is not justified. The specifications must be complete and definite, if the shipbuilder is to estimate intelligently the cost of the work. The operator is in an excellent position to know what has proven to be the most satisfactory under service conditions, and there is an increasing tendency among ship operators to have and maintain an adequate and efficient technical staff to collect data and incorporate the results in preparing specifications for new work. It is only persistent and careful attention to details of construction and operation that enables the operator successfully to meet competition. It is axiomatic that the time required to prepare complete specifications which will insure the proper performance by the shipyard of the work intended is very fruitful to both the operator and the shipbuilder. In practice, it has been found absolutely necessary to have complete specifications in order to secure a satisfactory job in accordance with the true intent of the specifications.

With reference to Mr. Wiley's statement that "The expense and folly of submitting detail plans for approval are not fully realized by the average operator," it is generally conceded that the quickest, best and most economical way in the long run is to work from plans which have been approved by the operator. Rarely, if ever, have the operators insisted on or attempted to "criticize and check the plans of every detail of construction * * *." The inference in the article to leave it to the yard does not work out well in practice.

The reference to the specifications on a "rush job" which required flanged copper pipe for steam heating system obviously refers to the recent reconditioning of the *President Polk* (ex-*Granite State*) at the Bethlehem Shipbuilding Corporation's Baltimore Dry Dock plant, is ill-advised. In this case, it should be remembered that much of this piping is run behind stateroom or public room sheathing or ceiling and that screwed pipe connections are not the best practice for this condition. The operator must constantly look ahead and avoid and reduce, wherever possible, maintainance and repair costs. Navy practice, even where pipes are exposed, advocates flanged copper pipe for all steam lines. Its many advantages are too well known to repeat here. The only disadvantage is its greater initial cost, but this is offset by the freedom from leaky joints and connections, the avoidance of which is so essential in the passenger ship services. Practically every big reconditioning job on passenger ships of recent date has specified flanged copper piping for steam heating systems; it may also be considered the standard practice of the International Mercantile Marine, United States Lines and other large passenger ship companies.

How can simpler specifications and less checking of detail plans result in increased effectiveness and decreased cost of inspection as noted in the article's summary? It must of necessity be just the contrary.

In treating a subject of this kind it is of prime importance to consider it also from the owner's or operator's viewpoint, for what is satisfactory to the operator will be satisfactory to the shipbuilders in the long run because without successful operation there will be little, if any, commercial building or extensive reconditioning in this country.

New York City. A. M. Youngquist.

Operators Should Pool Their Experience

Mr. Youngquist's statement that I treated the subject of simplification entirely from the builder's point of view is disappointing, as I had attempted not to, and had instanced several advantages to operators in addition to decreased first cost. In spite of "the excellent position" operators are in, they seldom agree in their requirements. Take at random the specifications of several companies in similar trades, and line up their requirements on rigging, piping, rail stanchions, etc. The writer has done this, much to his confusion. He has also seen prints of standard fittings which had already received signed approval from several operators returned

from other operators with a fillet increased here, a pin there, and so on. Standard plans or practices are not retained by builders which are usually rejected when proposed. Therefore, builders' standards, if brought together and fairly analyzed, would represent a broader "experience under service conditions" than any one operator possesses. That is what I suggested should be done. I also suggested that operators, with Mr. Hoover's aid, pool their experience and iron out their disagreements and contradictions, then let the builders know, for once and all, what they decide is wanted.

To propably 95 percent of the readers of MARINE ENGINEERING AND SHIPPING AGE, it was not obvious what ship I meant in my illustration on piping. The statement as to where the copper pipe is run on the *President Polk* should be amplified by adding the words "in third-class quarters," as that ship still has screwed pipe behind sheathing and ceiling in first-class quarters. Later and larger American passenger ships have screwed steam heat piping throughout. However, I did not condemn the change on its merits and specifically stated so. I am merely wondering which kind of pipe the next passenger ship I work on will have, and there is nothing to guide my guess.

Mr. Youngquist, in his last paragraph, appears to assign our shipbuilding difficulties to unsatisfactory quality rather than to excessive cost. It will be a new viewpoint to many, and one seldom appearing in the press.

Baltimore, Md. N. C. WILEY.

NEW BOOKS

STEAM TURBINES (Second edition, 1922). By William J. Goudie. Size, 6 by 9 inches. Illustrations, 329. Longmans, Green and Company, New York.

The second edition of this work, although carried out on the general scheme of the first edition, has been practically rewritten. On account of the rapid development of the geared marine turbine and the necessity of describing recent designs by the leading manufacturers, the work has been considerably enlarged.

The author appears to have had the viewpoint of students, designers and operators well in mind in compiling his book. The principles and methods of arriving at basic formulæ are clearly explained and illustrated by examples showing the methods of calculation. Although these calculations in many cases require the exercise of judgment in the selection of empirical coefficients, nevertheless the text is designed to be applied to given cases under arbitrarily assumed conditions.

Many of the designers and draftsmen, however, will take the principles and formulæ for granted or will decide from their own experience, having worked out a few of the formulæ, that the work is sound. They will, of course, modify some of the empirical coefficients to suit what their past experience has taught them and no doubt many of them will resolve to check the scaffolding upon which the text is built at their earliest opportunity.

The first portion of the text is devoted to detailed descriptions of the various turbines now on the market and this portion of the book should appeal to seagoing engineers and managers and foremen responsible for the erection of such machinery. They can easily get a good idea of the intricacies of the various designs from the sectional drawings which are profusely given.

From these drawings not only the inner working parts and their relation to each other can be discerned but also their relation to the complete installation. This is just what a number of the readers will want to know, and the book gives them a clear exposition of how the various turbines work, together with the whys and wherefores.

Much of the volume is strictly technical but there is considerable descriptive matter that can be read with comparative ease and, therefore, the volume should be a valuable addition to the library of both technical and practical men.

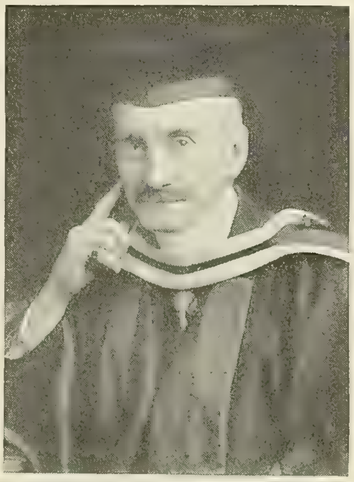
It should be noted that the work deals with the turbine proper only. As the author states, space is not available to take up the condensing plant or auxiliary machinery. Any matters relating to turbines, however, can be easily and quickly found by the aid of the comprehensive index.

PERSONAL MENTION

L. A. W. DOHERTY, general traffic manager of the Canada Steamship Lines of Montreal, has been made freight traffic manager of this company.

EDWARD P. FARLEY, of Chicago, vice-president in charge of sales of the Emergency Fleet Corporation, has resigned in order to return to private business.

DR. BRYSSON CUNNINGHAM, D.Sc., B.E., F.R.S.E., M. Inst. C. E., editor of the "Dock and Harbor Authority" and lecturer at the University of London on waterways, harbors and docks, will be in attendance this month at the annual convention of the American Association of Port Authorities at Toronto where he is scheduled to deliver an address on "Methods of Cargo Handling at British Ports." Dr. Cunningham has had an extended practical experience in dock and harbor engineering operations at various ports in Great Britain. For sixteen years he was assistant engineer in the service of the Mersey Docks and Harbor Board engaged on the construction of the Liverpool docks. In 1906 he became resident engineer with the London and India Docks Company and continued in this capacity upon the formation of the Port of London Authority. Late last year he left the service of the Port of London Authority in order to take up private practice in partnership with A. Havelock Case of Westminster.



Brysson Cunningham

J. BARSTOW SMULL, vice-president of the Emergency Fleet Corporation in charge of charters and allocations, has been elected president of the Corporation.

W. E. BURKE, in charge of the transportation department of the Canada Steamship Lines, has been appointed general traffic manager of this company with headquarters in Montreal.

COMMANDER F. P. BALDWIN, exclusive surveyor to the American Bureau of Shipping at Valparaiso, Chile, has resigned and will be succeeded by Alexander McBride, acting surveyor.

L. M. BRIMMER, formerly associate manager of the tank steamer department of the United States Shipping Board, has joined the staff of the Pierce Oil Corporation, 25 Broad street, New York.

W. J. Love, vice-president in charge of traffic of the Emergency Fleet Corporation, has been named vice-president and general manager.

H. S. Kimball, vice-president in charge of finance of the Emergency Fleet Corporation, has resigned. He will, however, act as fiscal agent of the Fleet Corporation in New York where negotiations are now being carried out for settlements with the pioneer purchasers.

H. Schreck was recently appointed chief engineer of the Diesel engine department of the Lombard Governor Company, Ashland, Mass. Mr. Schreck received his education at the Technische Hochschule of Berlin and obtained his early practical experience as a marine steam engineer. He has long been associated with the development and operation of Diesel engines having been for many years with one of the prominent shipyards in Germany in whose shops he superintended the manufacture of large Diesel marine units. While in Germany, he was active in the development of the first successful double acting two cycle marine Diesel engine which is still in service. After coming to this country Mr. Schreck entered the Diesel engine department of the Fulton Iron Works, St. Louis, Mo., as assistant chief engineer, later becoming chief engineer. Together with his new duties as chief engineer of the Lombard Company he will continue to act as consulting engineer to the naval architects, Messrs. Whittelsey and Whittelsey of New York.

H. Schreck

Clifton M. McBride, for two years assistant to the southern passenger manager of the International Mercantile Marine Company, has been appointed southern passenger manager to succeed Frederick T. DeCock, who has been transferred to the Baltimore office of the company.

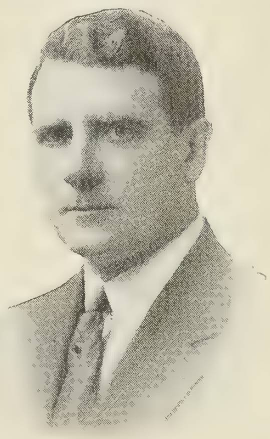
P. H. Lacy, formerly district director of the Shipping Board at Boston and later transferred to Savannah, has just been appointed district manager of the north Atlantic district which embraces all the ports between Montreal and Philadelphia. Mr. Lacy's headquarters will be at New York.

Sidney Henry, of Baltimore, director of sales of the Emergency Fleet Corporation, has been appointed to succeed Edward P. Farley as vice-president of the corporation in charge of sales. Mr. Henry graduated from the United States Naval Academy in 1901. After serving several years in the navy, he was appointed vice-president of the Baltimore Dry Docks and Shipbuilding Company, later assuming office with the Fleet Corporation.

Alfred H. Haag, marine superintendent for the Atlantic Gulf and Pacific Steamship Corporation of Baltimore, will this month become instructor of a new course in ship construction and operation which has been added to the curriculum of the Johns Hopkins University of Baltimore. Mr. Haag conducts a similar course in the George Washington University.

Calvin W. Rice, secretary of the American Society of Mechanical Engineers, has been appointed official delegate to the engineering congress to be held in connection with the International Exposition at Rio de Janeiro. For purposes of representation at the Congress Mr. Rice, who will act as emmissary of organized engineering in the United States, has been elected an honorary vice-president of the American Society of Mechanical Engineers. In addition to the American Society of Mechanical Engineers, Mr. Rice will represent at the Congress the Federated American Engineering Societies, the American Institute of Electrical Engineers, the Engineering Foundation, the John Fritz Medal Board, the Engineering Division of the National Research Council, the Engineers' Club of New York City and other organizations.

Joseph E. Sheedy, who has been acting vice-president of the Emergency Fleet Corporation in charge of operations, has been made vice-president of the Corporation. Mr. Sheedy has been connected with the shipping and shipbuilding industries since graduation from the Massachusetts Nautical Training School in 1903. He served as a commissioned officer in the Revenue Cutter Service for six years, resigning in 1901, when he became general superintendent with the Inter-Island Steam Navigation Company. He remained with this company for five years and then assumed the duties of assistant to the general manager of the Seattle Construction and Dry Dock Company. He has also been general manager of the Seattle North Pacific Shipbuilding Company; assistant to the president and general manager of the Downey Shipbuilding Company, and in September, 1921, European manager for the Emergency Fleet Corporation. He is a member of the Load Line Committee of the United States Department of Commerce and a member of leading naval and mechanical engineering societies in the United States.



Joseph E. Sheedy

OBITUARY

Francis S. Martin, consulting engineer and naval architect, died on July 27 at his home in Plainfield, N. J., after a two months' illness. He was born at Barrytown, N. Y., in 1852. Mr. Martin was graduated from the College of the City of New York, entered the shipyards of John Roach & Son, Chester, Del., and later was with Harlan & Hollingsworth Company, Wilmington. For the past forty years he has maintained in New York City an office for the surveying, designing, appraising and superintending the construction of ships of all classes. In 1917 Mr. Martin was appointed chairman of the Board of Survey and Consulting Engineers of the United States Shipping Board to take charge were put into American service. Mr. Martin was also for the Shipping Board one of the three members of The Ocean Advisory Board on Just Compensation. Throughout his many years as a marine surveyor, Mr. Martin has been instrumental in deciding many maritime litigations and in all these his position has been synonymous with fairness and justice. During all of his long business career and especially by his valuable services to the United States Government he attained an international reputation for faithfull service to all clients.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Bids to Be Taken This Month for Red "D" Ships; Three Types of Propulsion to Be Figured

Alternative Proposals Will Be Submitted for Reciprocating, Turbine and Diesel Engines—Principal Features of Machinery Specifications

BIDS were scheduled for receipt in September for the construction of two steel passenger and cargo ships for the Red "D" Line, which have been designed by Theodore E. Ferris, naval architect and marine engineer, of 30 Church Street, New York City. Proposals have been asked for ships propelled by reciprocating, turbine or Diesel engines.

The vessels will each have an over all length of 320 feet, will be of the two-deck shelter deck type, driven by twin screws and will be equipped to carry about 50 first class and 25 second class passengers. The ships will be built to American Bureau classification. Principal details regarding the proposed propulsion installations, for which prices have been asked, are as follows:

Reciprocating Engines

In the case of reciprocating engines, the machinery will consist of two return tube four-furnace, single-ended Scotch boilers about 16 feet inside diameter by 11 feet 8 inches long, fitted for burning oil, and two vertical, inverted direct acting, three-crank triple expansion engines with cylinders 18 by 29 by 47 inches diameter with 30-inch stroke. The engines are to be capable of making 120 revolutions and to develop a total of about 2,200 indicated horsepower.

The boilers are to be designed for a working pressure of 190 pounds per square inch.

The hull machinery will include a steam windlass, steam and hand steering gear, steam winches, warping winch and deck pumps.

There is to be one main condenser, cylindrical in shape and independent of the main engine, to contain about 3,400 square feet of condensing surface, the tubes to be seamless drawn ¾ inch.

There is to be located in the fireroom one vertical wet uptake starting boiler built for a working steam pressure of 190 pounds per square inch, the boiler to be about 3 feet inside diameter and 101 inches high, to have sufficient capacity for supplying steam to the fire pump and to run the oil fuel burning system. This boiler will be coal fired. The furnace fronts of each main boiler are to be arranged for burning oil fuel, interchangeable to coal burning, on the White, Dahl, Coen or other approved system.

Motorship Machinery

As motorships, the vessels will be driven by twin screws each propeller being driven by one six-cylinder four-cycle Diesel oil engine of the Polar type, manufactured by the McIntosh & Seymour Corporation, each engine being capable of developing 900 shaft horse-power making 140 revolutions per minute.

The auxiliaries in this case will be electrically driven and will comprise auxiliary engine, generator and compressor;

Each engine will be of the heavy duty marine type Diesel, with cylinders 22 inches in diameter and 32 inch stroke. They will be of the inclosed type with three stage compressors mounted on the forward end and driven from the crank shafts.

The auxiliary boiler to be located in the engine room will be of the vertical wet uptake or return tube type fitted with corrugated furnaces and having sufficient capacity to furnish steam at 150 pounds pressure. It will be oil fired and contain about 600 square feet of heating surface.

Turbine Propulsion

If turbine engines are decided upon the machinery will be a twin screw installation consisting of two independent sets of the latest design De Laval double reduction gear steam turbines and two cylindrical, return tube Scotch boilers, 16 feet 8 inches inside diameter by 11 feet long, the boilers being built for a working pressure of 185 pounds per square inch with 150 degrees of superheat and one starting boiler of the vertical wet uptake type, 3 feet inside diameter by about 101 inches high, built for 175 pounds per square inch working pressure.

Each turbine set will consist of one high pressure ahead and astern turbine unit driving a pinion through a double reduction gearing. The revolutions of the turbines at full speed ahead will be 4,000 per minute developing not less than 2,000 shaft horsepower and driving the propeller at 115 revolutions per minute.

The boilers will be arranged for burning oil fuel, interchangeable for coal burning, on the White, Dahl, Coen or other approved system and will also be fitted with the Howden's system of heated forced draft. Provisions are also made for the necessary auxiliary machinery, pumps, etc.

Main condensers will contain about 1,600 square feet of cooling surface and will be fitted with tubes ¾ inch outside diameter, the auxiliary condenser containing about 1,200 square feet of cooling surface with tubes ¾ inch outside diameter. There will be two 8-inch diameter main circulating pumps driven by vertical single-cylinder engines.

The two main boilers will be of the four furnace marine type.

Cleveland Yard to Build Another Steel Freighter

THE American Shipbuilding Corporation, of Cleveland, Ohio, has been awarded a contract by Pickands Maher & Company, of Cleveland, for the construction of a 600-foot steel cargo carrier for use on the Great Lakes.

The ship will have a deadweight tonnage of approximately 12,000, driven by a triple expansion reciprocating steam engine, and makes the fifth ship of this type contracted for in the Lake district so far this year. It is expected she will cost about $800,000.

Contract Placed with Federal Yard for Nine Boilers

THE contract for the construction of nine boilers has been awarded to the Federal Shipbuilding Company, of Kearny, N. J., by the Luckenbach Steamship Company. For what particular purpose the boilers are being constructed was not announced.

The boilers will be of the Scotch marine type, 17 feet 6 inches in diameter by 13 feet long and will be built for 225 pounds pressure. Each will have four 44-inch furnaces and will be oil burning, using forced draft. The boilers will be equipped with 2½-inch tubes and will have 4,380 square feet of heating surface. It is understood that they will be built at a total cost of approximately $170,000.

Single Screws, Motor Driven, for Two Munson Liners

IT is learned that the Munson Line, which was considering two alternative propositions with regard to the conversion to motorships of the steamships *Courtois* and *Covedale*, has decided to convert the vessels into single screw ships, the *Courtois* having arrived at the plant of the Sun Shipbuilding Company, Chester, Pa., during the past month.

The *Courtois* will be equipped with one of the two 900-brake horsepower McIntosh & Seymour oil engines purchased by the Munson Line from the Shipping Board. The engine is of the four-cycle six-cylinder type developing 140 revolutions and is expected to drive the ship at about 8 knots. A new Scotch auxiliary boiler having about 1,000 square feet of heating surface will be installed. The work will cost about $60,000.

Chairman Lasker Announces Changes In Shipping Board

A. D. LASKER, chairman of the United States Shipping Board, has made the following announcement of changes in the personnel of the Emergency Fleet Corporation:

H. S. Kimball, New York, vice-president in charge of finance, has resigned, to become effective at once. He will, however, act as fiscal agent of the Fleet Corporation in New York, where its largest accounts are located and where negotiations are now being carried out for settlements with the pioneer purchasers. He will be succeeded by his assistant, Col. Joseph W. McIntosh, Chicago, former chief of subsistance of the U. S. Army, who now becomes a trustee of the Fleet Corporation.

Edward P. Farley, Chicago, vice-president in charge of sales, has also resigned, to become effective at once. Mr. Farley, it is understood, is to return to private business. He will be succeeded by Sidney Henry, of Baltimore, now director of sales, who now becomes a trustee of the Fleet Corporation. Mr. Henry is a graduate of the Naval Academy, class of 1901.

Mr. Lasker stated that Vice-president J. Barstow Smull, in charge of charters and allocations, has been elected president of the Fleet Corporation, and W. J. Love, now vice-president in charge of traffic, has been named vice-president and general manager.

Referring to the reported severance of the connection of August F. Mack with the Fleet Corporation, as district manager of the New York district, Mr. Lasker stated that Mr. Mack had agreed to remain with the Fleet Corporation for an indeterminate period.

Diesel Passenger and Freighter Is Contracted For

THE contract for the construction of a motor driven combination freight and passenger vessel has been awarded to the Murnon Shipbuilding Company, of Mobile, Ala. The vessel will be 120 feet long, driven by two 120-horsepower Kahlenburg Diesel motors. The vessel was designed by Cox & Stevens, naval architects, New York City.

Sun Shipbuilding Company Is Lowest Bidder for Construction of Four Diesel Electric Dredges

Chester, Pa., Company's Prices Lead Field of Sixteen Bidders Including Four Navy Yards—All Seaboard Sections of Country Represented in Competition

WITH a price of $653,080 for one; $1,300,160 for two; $1,920,240 for three, and $2,528,240 for four, the Sun Shipbuilding Company, of Chester, Pa., submitted the lowest bid for the construction of seagoing Diesel-electric hopper dredges for the Government, at the opening of tenders by the Chief of Engineers, War Department, Washington, D. C., on August 2. The Boston Navy Yard submitted the second lowest bid with a price of $2,610,000 for four vessels, and the New York Navy Yard submitted the highest bid for the four vessels, at $3,631,708.

Sixteen tenders were submitted, including four navy yards. The bids are as follows:

Bidder	1 Dredge	2 Dredges	3 Dredges	4 Dredges
Sun Shipbuilding Co., Chester, Pa.	$653,080	$1,300,160	$1,920,240	$2,528,240
Boston Navy Yard, Boston, Mass.	......	......	......	2,610,000
Todd D. D. & Constr. Co., Tacoma, Wash.	750,000	1,433,000	2,107,000	2,676,000
Bethlehem Shipbldg. Corp., New York .	742,000	1,458,000	2,140,000	2,798,000
Merchant Shipbldg. Co., Chester, Pa. ..	799,000	1,499,000	2,159,000	2,799,000
Puget Sound Navy Yard	775,000	......	......	2,900,000
Newport News S. B. & D. D. Co.	......	1,532,000	2,255,000	2,976,000
Staten Island Shipbuilding Co.	783,000	1,519,000	2,250,000	2,980,000
Federal Shipbuilding Co.	861,999	1,617,104	2,335,290	3,033,648
Moore Shipbldg. Co., Oakland, Cal. ..	861,925	1,674,150	2,484,375	3,265,100
Bath Iron Works, Bath, Me.	963,000	1,818,000	2,672,000	3,527,000
New York Shipbldg. Corp., Camden, N. J.	978,500	1,835,000	2,691,000	3,547,000
Los Angeles S. B. & D. D. Co.	948,000	1,828,000	2,698,000	3,578,000
New York Navy Yard, Brooklyn, N. Y.	......	1,907,269	......	3,631,708
Mare Island Navy Yard	869,397	1,678,833	......	......
H. E. Crook Co., Inc., Baltimore, Md. ..	874,000	1,710,000	......	......

Charleston Yard Lowest Bidder for New Dredge Hull

THE Charleston Dry Dock & Shipbuilding Company, Inc., of New Orleans, with a price of $25,850, submitted the lowest tender for the construction of a steel dipper dredge hull for the United States District Engineer Office, Montgomery, Ala. Proposals were opened at 11 a.m., on July 31, the bids submitted being as follows:

Charleston Dry Dock & Shipbuilding Co., Inc. (New Orleans)	$25,850
Tampa Shipbldg. & Engineering Co.	29,000
Charleston Dry Dock & Machine Co.	33,921
Milwaukee Bridge Co.	36,450

Coast Guard May Build New Ship; to Overhaul Seminole

THE construction of a new Coast Guard cutter and the reconditioning of one of this type of vessel now in service is in contemplation by the United States Coast Guard Service, at Washington, D. C. Whether or not a new construction contract will be placed this fall depends upon the action of Congress on the bill recently introduced for the construction of a new cutter to replace the *Bear*.

The Coast Guard Service also expects to place the cutter *Seminole* out of commission this fall for the purpose of reconditioning and general overhauling before she assumes duty on a new station to be determined later.

Reboilering and Reconditioning of Coast Guard Cutter Gresham Goes to Staten Island Shipbuilding Co.

THE Staten Island Shipbuilding Company has been awarded the contract for reboilering and reconditioning of the United States Coast Guard cutter *Gresham*, following the recent opening of bids at Washington, D. C.

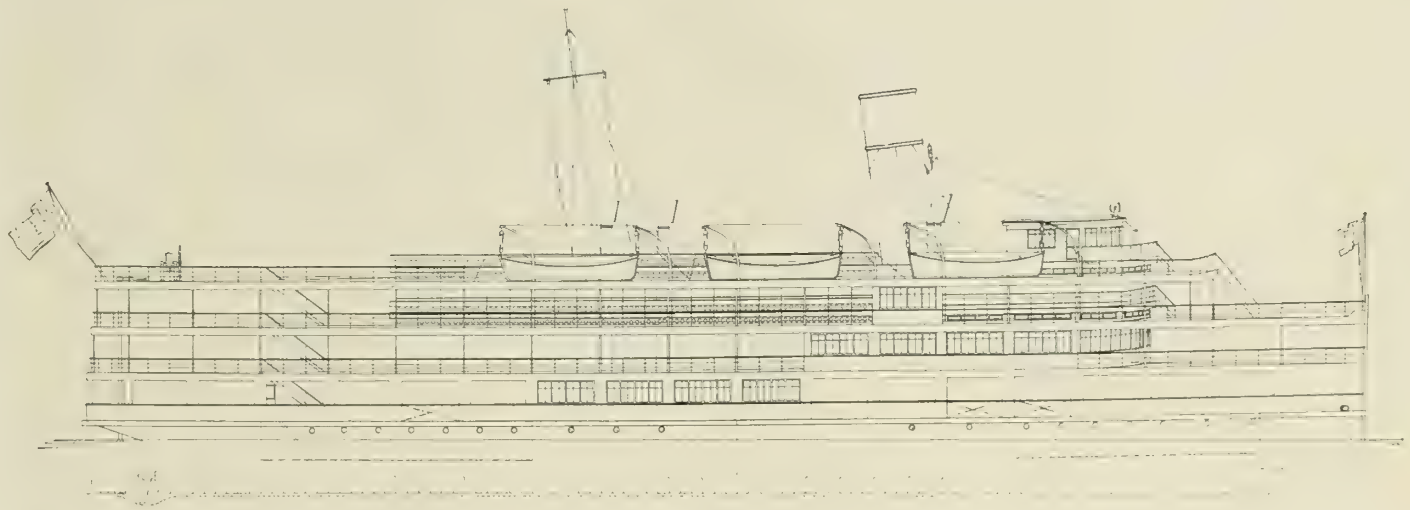
Three proposals were submitted, Bid No. 1 dealing with items of work directly related to converting the *Gresham* into an oil burning vessel; Bid No. 2, hull repairs such as outside plating and work upon which no lump sum bid could be expected; and Bid No. 3, items not necessarily related to the conversion of the vessel to burn oil. The prices submitted were as follows:

List of Bidders	Bid No. 1	Bid No. 2	Bid No. 3
Newport News	$60,705	15	$44,730
Todd Shipbuilding Corp.	68,350	25	29,500
Morse Dry Dock & Repair Co.......	75,670	22	37,350
Maryland Dry Dock	67,578	24	37,311
Staten Island Shipbuilding Co........	71,500	30	21,400
Bethlehem Shipbuilding Co...........	81,847	25	36,953
Sun Shipbuilding Co.	85,080	20	41,065
Federal Shipbuilding Co.	92,890	20	21,984
W. & A. Fletcher....................	85,000	22	45,000

Fletcher Yard to Convert Carfloat Into a Hospital

THE W. & A. Fletcher Company, Hoboken, N. J., has been awarded the contract for the conversion of a car float into a floating hospital for the Auxiliary of the Tubercular Division of Bellevue Hospital, which is under the direction of Dr. James Alexander Miller. Plans and specifications for the work were prepared by the firm of Cox & Stevens, naval architects, New York City, who will also have supervision of the conversion.

The vessel is 240 feet in length with 60 feet beam, upon which a two-story structure, to have in it wards, recreation rooms, etc., will be built. The contract, which involves about $40,000, is scheduled for completion early in the fall.



Outboard Profile of New Day Steamer, Designed by George Sharp, New York Naval Architect, for Wilson Line.

Pusey & Jones Low Bidder for Construction of 3,000-Passenger Steamer for Use on Delaware River

George Sharp, New York Naval Architect, Designs Vessel With New Features for Wilson Line—Ship Will Be 220 Feet in Length, Built of Steel and Steam Driven

THE Pusey & Jones Company, of Wilmington, Del., with a total price of $529,000 for two day passenger steamers driven by reciprocating engines and $599,000 for the same steamers if driven by turbine engines, submitted the lowest bids for new vessels for the Wilson line, of Wilmington and Philadelphia, at the opening of tenders on August 17. The bids were received by George G. Sharp Company, naval architects and consulting engineers, 30 Church street, New York City, who designed the vessel.

The proposed vessel is designed to carry 3,000 passengers. She will be a single screw steamer equipped with triple expansion steam engines and watertube boilers, to develop a speed of 18 statute miles and will have a length of about 220′ 0″. The vessel will be built of steel throughout with three complete passenger decks and shade or boat deck.

The men's smoking room, ladies' cabin and lavatories will be situated on the main deck, along with luncheon counter, and on the saloon deck there will be a large open air ball-room 84 feet long by 36 feet wide without obstruction of any kind except bandstand. Forward of the dancing space on this deck, there will be a large observation and refreshment room extending the full width of the vessel. The remainder of the deck forward and aft and at sides of dancing space will be available for passengers.

Above the saloon deck is the observation deck, which is entirely open. One of the features for the comfort of passengers is that this deck is terraced at three levels giving unobstructed vision to all passengers, the levels of the shade deck being arranged in a similar manner and the space between the different levels being open permits of the free circulation overhead of air and light to the passengers on the observation deck.

Federal Yard Is Awarded Standard Oil Repair Job

THE Federal Shipbuilding Company, of Kearny, N. J., has been awarded the contract for repairs to the steamship *S. B. Hunt*, of the Standard Oil Company of New Jersey, following the opening of bids on August 9.

Alderton Company Is Low Bidder for Invincible Repairs

THE Alderton Dry Dock Company submitted the low bid for the work of general overhauling of hull and engines on the electric-drive ship *Invincible*, at the opening of tenders by the Shipping Board, at 45 Broadway, New York, on August 8.

Staten Island Co. Gets Repair Job on Steamer Suboatco

THE Staten Island Shipbuilding Company, with a price of $13,590 and 10 days' time, was awarded the contract for repairs to the freight steamer *Suboatco*, of the Transmarine Corporation, following the opening of bids by that company at 5 Nassau Street, New York, on August 8.

Tietjen and Lang Yard Awarded Oil Conversion Contracts

THE steamships *Medina*, of the Mallory Line and the *Pawnee*, of the Clyde Line, are at the Tietjen & Lang plant of the Todd Shipyards Corporation, Hoboken, New Jersey, for conversion from coal to oil burning.

Bids to Be Asked This Fall for Two Clyde Line Ships

INFORMATION obtained recently by MARINE ENGINEERING AND SHIPPING AGE leads to the belief that bids will probably be asked early in the fall for the construction of two coastwise passenger and freight ships for the Clyde Line.

Unofficial estimates placed the probable cost of these vessels at about $1,500,000 each. Theodore E. Ferris, naval architect and marine engineer, of 30 Church Street, New York City, has begun the work of preparing tentative plans and specifications for these proposed vessels although it is not thought likely that they will be put out for bids before October.

It is understood that the new ships will be about 425 feet in length, of the same general type as the Clyde Line steamship *Lenape*, with larger and more extensive passenger accommodations and greater speed. Propulsion will probably be by turbine engines and the new ships will replace the steamships *Apache* and the *Arapahoe*.

Aero Alarm Co. Gets Installation on S. S. Leviathan

THE Aero Alarm Company, Inc., of Seattle, Washington, through its New York office, has been awarded the contract by the Newport News Shipbuilding Company for installation of the Aero alarm system on the steamship *Leviathan*, now undergoing reconditioning at Newport News, Va. The company is also making additions to the Aero alarm system on the steamships *America* and *George Washington* and has contracted through its Los Angeles office to extend the system on the Admiral Line steamship *Ruth Alexander*.

Through its Los Angeles office, the same company has installed the Aero system on the steamships *Yale* and *Harvard*; will extend the Aero alarm system on the steamship *City of Los Angeles*, and through its Seattle office has been awarded the contract to extend the system on the steamships *President Madison* and *President Cleveland*.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Steamship Drydocked, Chester, Pa.—American steamship Argus was drydocked at Sun Shipyards for repairs.

Crowley Contracts, San Francisco, Calif.—Three sub-chasers and cutter Tulare were taken to Crowley yards for overhauling.

Propeller Fitted, Baltimore, Md.—Lighthouse tender Maple was hauled at Spedden's shipyard to be fitted with new bronze propeller.

Schooner Drydocked, Los Angeles, Calif.—Four-masted steam schooner Ella A. was drydocked for hull cleaning, painting and general repairs.

Steam Schooner Drydocked, San Francisco, Calif.—Steam schooner Fort Bragg was drydocked on ways of the Barnes & Tibbitts dock to undergo overhauling.

Repairs to Lighthouse Tender, Norfolk, Va.—Lighthouse tender Orchid went to yard of Norfolk Shipbuilding and Dry Dock Company for docking and repairs.

Contract Awarded, Brooklyn, N. Y.—Morse Dry Dock and Repair Company was awarded contract for overhauling and reconditioning the steamship City of Alton.

Tanker Drydocked, San Francisco, Calif.—British tanker El Grillo went to Bethlehem yards to be drydocked for cleaning and painting and to have tailshaft drawn.

Steamer Overhauled, West Coast.—U. S. Quartermaster steamer Captain Anton Springer went to Georgetown shipyard to undergo general overhauling.

Launching of Ship, Wilmington, Del.—The first of two ships, contracted for by Pusey & Jones for the Seaboard-Bay Line, was launched July 25. The ship will be the State of Maryland.

Contract Awarded, Wilmington, Del.—Pusey & Jones Shipbuilding Company was awarded contract to construct a steel floating grain elevator, 100 feet long, for the Pennsylvania Railroad.

Contract Awarded, Kearny, N. J.—Federal Shipbuilding Company was awarded contract for repairs to the steamship S. B. Hunt, of the Standard Oil Company of New Jersey. Price $15,738.

Temporary Repairs, San Pedro, Calif.—Crowell & Thurlow freighter William A. McKenney, damaged in collision, went to Los Angeles Shipbuilding and Dry Dock Corporation for temporary repairs.

Reboilering and Reconditioning, Staten Island, New York.—Staten Island Shipbuilding Company was awarded contract for reboilering and reconditioning United States Coast Guard cutter Gresham.

Bids for Two Clyde Line Ships.—Bids will probably be asked early in the fall for construction of two coastwise passenger and freight ships, 425 feet long, for Clyde Line. Approximate cost, $1,500,000 each.

Steamship Conversion, Brooklyn, N. Y.—Steamship Comus, of the Southern Pacific Steamship Company, went to the plant of Robins Dry Dock & Repair Company to be converted from coal to oil burner.

Steamer Repairs, Staten Island, N. Y.—Staten Island Shipbuilding Company, with price of $13,950 and 10 days' time, was awarded contract for repairs to freight steamer Suboatco, of the Transmarine Corporation.

Newport Shipbuilding Contracts, Newport News, Va.—Plant of Newport News Shipbuilding & Dry Dock Company repaired steamship Deepwater, from Constantinople, schooner Moonlight and steamers Cowan and Comparle.

Robins Shipyard Awarded Repairs, Brooklyn, N. Y.—Robins Dry Dock & Repair Company, of the Todd Shipyards Corporation, was awarded contract for repairs to the British steamship Andree. Price $45,850. Time 24 days.

Conversion to Motorships, Chester, Pa.—Steamships Covedale and Courtois, recently purchased by Munson Line from Shipping Board, were awarded to Sun Shipbuilding Company for work of conversion to motorships.

Turbine Engine Overhauling, Seattle, Wash.—Shipping Board awarded contract to Todd Drydocks Corporation plant at Harbor Island, Washington, for purpose of having her turbine engines completely overhauled.

Conversion to Oil Burner, Mobile, Ala.—Steamer Osage, of Moore & McCormack fleet, is to be changed from a coal burner to an oil burner and generally reconditioned by Todd Shipyards Corporation, at cost of $60,000.

Steel Hull for Steamer, Jeffersonville, Ind.—Howard Shipyards, of Jeffersonville, Ind., was awarded contract for construction of a steel hull for the excursion steamer East St. Louis, to be placed during the winter.

Dredge Repair Contract, Oakland, Calif.—The Hanlon Dry Dock & Shipbuilding Company was awarded contract by United States Engineer for repairing two 20-inch pipe line dredges and auxiliary floating plant. Price $2,176.

Trial Trip, Poughkeepsie, N. Y.—The official trial trip of the new ferryboat Poughkeepsie took place from the foot of Main street, Poughkeepsie, N. Y. The boat will go into service for the Poughkeepsie and Highland Ferry Company.

Contract Awarded, Oakland, Calif.—Shell Oil Company awarded contract to Union Construction Company for a 4,000-barrel oil barge costing $175,000. Barge to be used for bay transportation. She will probably be completed in September.

Fireboat, New Orleans, La.—The Johnson Iron Works, Dry Dock & Shipbuilding Company, Inc., was awarded contract for construction of steel screw fireboat for city of New Orleans. Price $264,447, boat to be completed in 220 days.

Annual Inspection, San Francisco, Calif.—Captain Andrew Dixson's yacht and the lumber carrier Brooklyn of Sudden & Christenson, went to Barnes & Tibbets yards, the latter vessel to undergo annual overhauling, drydocking and inspection.

Contract Award, Newport News, Va.—The Newport News Shipbuilding & Dry Dock Company was awarded contract for construction of two combination passenger steamers for Ocean Steamship Company, of Savannah. Price $920,000 each ship.

Contracts on West Coast.—New tanker F. H. Hillman of the Standard Oil Company, went on drydock at Hunter's Point for minor adjustments and the Casco of Swayne & Hoyt's fleet went on No. 3 drydock of the Bethlehem Shipbuilding Company.

Repairs and Inspection, Johnson Dry Docks.—The Cuban steamers Ramon Miramon and Edourdo Sala, recently purchased by D. Sullivan and Company, of Chicago, for operation on the Great Lakes, underwent repairs and inspection by government steamboat inspectors at the Johnson Docks.

Conversion to Cableship, Seattle, Wash.—War Department contract for converting steamship Dellwood into a cableship went to Todd Dry Docks, Incorporated, of Seattle. The Dellwood is one of 8,800-ton cargo steamers built for the Shipping Board during the war. Amount of expenditure involved is $200,000.

Conversion Contracts, Hoboken, N. J.—Tietjen & Lang, of Todd Shipyards Corporation, were awarded contract for reconditioning steamships Medina, of the Mallory Line, and Pawnee, of the Clyde Line, from coal to oil burners. Approximate cost, $100,000. The yard also installed Best oil burning system in New York Central tug No. 18.

Steel Freighter, Cleveland, O.—The American Shipbuilding Corporation, of Cleveland, Ohio, was awarded contract by Pickands, Maher & Company, of Cleveland, for construction of a 600-foot steel cargo carrier for use on Great Lakes. Deadweight tonnage about 12,000, driven by triple expansion reciprocating steam engine. Probable cost, $800,000.

Carfloat Conversion, Hoboken, N. J.—W. & A. Fletcher Company, Hoboken, N. J., was awarded contract for conversion of car float into a floating hospital. Plans and specifications prepared by Cox & Stevens, naval architects, New York City. Vessel is 240 feet long, 60 feet beam. Two-story structure, to have wards, recreation rooms, etc. Price about $40,000.

Construction of Tugs, Brooklyn, N. Y.—Orders for construction of three steel single screw tugboats for the New York Central were placed with the Tebo plant, of the Todd Shipyards Corporation. Delivery expected end of January, 1923. Boats to be oil burning equipped with Todd merchanical oil burners. Over all length 108 feet, beam 25 feet 6 inches, molded depth 12 feet 9 inches.

Construction Contract, Mobile, Ala.—Contract for the construction of a motor-driven combination freight and passenger vessel was awarded to the Murmon Shipbuilding Company, of Mobile, Ala. Vessel will be 120 feet long, driven by two 120 horsepower Kahlenburg Diesel motors. Designed by Cox & Stevens, naval architects, New York City. Scheduled for delivery in November.

Work at Union Iron Works, San Francisco.—Ferryboat San Mateo, constructed by Union Iron Works for Six-Minute Ferry Company, went on drydock for minor adjustments. Contract was awarded the Union Iron Works for repairs to the Matson liner Wilhelmina, damaged in collision with steamer Maui. More than 110 feet of deck rail on the starboard side, as well as stanchions, were to be replaced.

Shipyard Activities, West Coast.—Freighter Grace Dollar went on Hunter's Point Drydock to have tail shaft drawn and undergo general repairs. Tanker William F. Herrin and steamer Northland went to Union Iron Works drydocks for cleaning, painting and general overhauling, and steam schooner Claremont of Hart-Wood Lumber Company went to Alameda plant of the Bethlehem yards to undergo hull repairs.

New York Harbor Work.—A Munson Line tug was awarded to the New York Harbor Dry Dock Company for completion, the work including installation of oil engines, bulkheads and tanks, putting on of superstructure, etc., at a total cost of close to $12,000. The vessel will be used in Cuban waters. The shipyard was also awarded the job of reconditioning the Shipping Board steamer West Elcasco at a price of $7,835.

Refrigeration Space on Steamship, Chester, Pa.—Sun Shipbuilding Company, of Chester, Pa., was awarded contract to insulate and convert steamship San Lorenzo, of the New York and Porto Rico Steamship Company, into an air-cooled freight carrier. Brunswick Refrigerating Company's machinery will be used and ship will have about 120,000 cubic feet of cargo space. Price submitted $138,768; time 60 running days.

To Build New Tug, West Coast.—David W. Dickie, naval architect, completed specifications for new tow boat to be built for Coos Bay Lumber Company. Tug was designed for towing purposes and will contain a 165 horsepower engine, with a hull fifty-seven feet long and sixteen-foot beam. Vessel will have a very large engine room and be controlled from the pilot house. Craft will cost about $30,000 and will be used to tow log rafts from Oakland harbor to Bay Point.

Conversion Into Single Screw Ships.—Munson Line will convert steamers Courtois and Covedale into single screw ships. Courtois went to Sun Shipbuilding Company, Chester, Pa., to be equipped with one of the two 900-brake horsepower McIntosh & Seymour oil engines purchased from the Shipping Board. New Scotch auxiliary boiler having about 1,000 square feet of heating surface will be installed. Work to cost about $60,000.

Contract Awarded, San Francisco, Calif.—Standard Oil Company has awarded contract to the Bethlehem's California yard for the construction of a tank vessel of 12,000 barrels' capacity. The boat is to be finished by December. It will be equipped with an electric drive from two generators driven by two Werkspoor Diesel engines. The new ship is to have a length of 230 feet, beam 40 feet, depth 16 feet 6 inches and a speed of 10 knots. She will trade up and down the Pacific Coast.

Repair Contracts, Hoboken, N. J.—Steamship Cour d'Alene, of the Bull Line, went to W. & A. Fletcher Company's yard to be drydocked, have stem taken out and straightened, replaced, crumpled plates made good and fore peak tanks proved tight. The yard was also awarded Bull Line steamship Ellenor for repairs, steamship Elizabeth of the same line for general repairs, Shipping Board steamship Lavada, steamship Mount Carroll of the United American Line and the Standard Oil barge Socony No. 86.

Steamer Wanted, Ecuador.—An Ecuadorean firm is inquiring in southern marine circles to ascertain if they can purchase a new or second-hand oil burning steamer with accommodation for between thirty and forty passengers in the first class, fifteen to twenty-five in the second class and with cargo space for about 150 head of cattle and at the same time capable of maintaining a speed of ten to sixteen knots. Vessel will probably be placed in trade between Ecuador and the Galapagos Islands. The name of the intending purchaser or further details may be secured from Mr. George H. McCloud, United States Department of Commerce, Bureau of Foreign and Domestic Commerce, Room 214 Custom House, New Orleans, La.

SHIPYARDS AND DRY DOCKS

Corporation to Enlarge Plant, Staten Island, N. Y.—New York Harbor Dry Dock Corporation plans to install an additional 10,000-ton dock at its plant in Rosebank, Staten Island, adjoining the twelve new piers just completed by the City of New York. To provide additional berthing space required, an additional tying-up pier will also be constructed. The corporation has purchased the two 10,000-ton drydocks previously leased from the Shipping Board. One and three-quarter million dollars of new money has been put into the enterprise and a larger corporation has been formed. When shipping conditions improve, the new company anticipates increase in its repair work of both American-owned ships and foreign ships.

Dry Dock Company to Move Plant, Mobile, Ala.—Alabama Dry Dock and Shipbuilding Company will transfer all of its operations to Pinto Island, moving all of its big machinery of the machine shop, plate shop and other departments now located on the west side of Mobile river to the island where the large dry docks of the firm are located. R. D. Dunlap, president of the company, announced that the entire plant will be located on the east side of the river. At the Pinto department the Alabama firm has its large 10,000 ton sectional dry dock, its large Pinto dock and several smaller dry docks. With the removal of all departments to the Pinto site, the company will better be able to take care of its big repair jobs. The Alabama firm will keep only one department on the west side of the river. The small cradle ways at this department, used in hauling out sailing vessels and small steam craft, will be the only part of the big ship repair and dry docking concern to be left on that side. Considerable money will be spent in the erection of new buildings and installing machinery at the Pinto Island plant, according to a statement by Mr. Dunlap.

PORT IMPROVEMENTS

Seawall, Aransas Pass, Tex.—Attorney General's Department, Austin, approved $213,000 bond issue for seawall. Address Mayor.

Harbor Contract Planned, Norfolk, Va.—Three hundred thousand dollars each has been allotted for improvement of Thimble Shoal Channel and Norfolk Harbor.

Wharfing Facilities, Seattle, Wash.—Ames Shipbuilding & Dry Dock Company has been granted permission to extend the present wharfing facilities at their site 509 feet, work to be started at once, it is understood.

Contract Award, Portland, Me.—Directors of Port of Portland, 67 Commercial street, awarded contract for construction of north and south sheds and grain conveyor gallery, State Pier, Contract 10, to M. A. Long Company, 1523 Munsey Building, Baltimore, Md.

Dredging, Brooklyn, N. Y.—Superintendent of Public Works, Albany, N. Y., awarded contract to Taylor Dredging Company, Communipaw Ave., Jersey City, N. J., for dredging portion of Henry Street Slip at Gowanus Bay, Terminal Contract 90. Price $19,085.

Seawall, Annapolis, Md.—Specification 4621.—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded contract for constructing a seawall at Naval Academy to McLean Contracting Company, Fidelity Building, Baltimore, Md. Price $14,350 (120 days).

Contract Awarded, Chicago, Ill.—Great Lakes Dredge & Dock Company, 104 South Michigan avenue, Chicago, Ill., was awarded contract by Harbor & Dock Commissioner, of Troy, N. Y., for constructing dock wall, also improving and regulating river and dock front at Troy. Price $582,795.

Contract Awarded, Brooklyn, N. Y.—J. H. Delaney, Commissioner of Docks, Pier "A," North River, New York, awarded contract to Riverside Contracting Company, 164 Montague street, for building ramp and dumping board at foot of West 23d street, Coney Island Creek, and completing dredging.

Pier Contract Placed, Norfolk, Va.—J. T. Nuchols Company, Richmond, Va., was awarded contract for rebuilding Chesapeake & Ohio pier and warehouse, burned at Norfolk, several months ago. Amount of contract not made public, believed to be not less than $125,000. New pier and warehouse will be of fireproof, constructed of reinforced concrete and steel, 450 by 52 feet, approximately, and will more than compensate for space lost when original structure burned.

Port Developments and Improvements, Texas.—A total appropriation of $1,571,000 has been authorized by the Rivers and Harbors Commission for the development and maintenance of Texas ports. The appropriation includes $750,000 for completion of the Houston ship channel, $240,000 for maintenance work on Galveston harbor and channel, $100,000 on Texas City harbor and channel, $20,000 for Port Bolivar, $300,000 for Beaumont, Port Arthur and Orange, $61,000 for Caddo Lake dam and $100,000 for other projects.

New Orleans Improvements.—Projects on the city front under way, authorized by the dock board or for which plans have been completed call for an expenditure of $2,200,000, according to Mr. Walsh, general manager. By the end of the year this entire project will be in full swing. Meanwhile plans are to be drawn for other improvements on the city front, the financing for which was provided by the dock board last December, shortly after the board was reorganized under the new state law. The work at the four wharves mentioned will require expenditure of $1,500,000. Plans have been approved for reconstructing the Seventh Street landing, building a shed, and rat-proofing the wharf, at a cost of $250,000. The Robin street shed is to be rat-proofed and widened, sheds added at Celeste and Market streets, and the latter wharves also rat-proofed, in addition to the raising of the levee.

NEW INCORPORATIONS

Harlem Navigation Company, capital $140,000, chartered in Delaware.

The Braeger Shipping Company, of Manhattan, capital $100,000, chartered at Albany, to do business as export freight contractors and brokers. F. Braeger, W. Proksch and A. Begg, incorporators.

The United States Trade Line Company, capital $1,000,000, chartered under Delaware laws to operate boats. New York Register & Transfer Company, attorneys.

Norma Steamship Corporation, capital $150,000, chartered under Delaware laws. Incorporators: Alva F. Wallander, H. Victor Crawford, and George C. Sprague. Mr. Crawford and Mr. Sprague, lawyers, with offices at 120 Broadway, New York City.

FOREIGN ACTIVITIES

New Vessel, Scotland.—Tenders have been called for among Clyde shipbuilders by a shipowning company who are in the market for a 12,000-ton ship.

Doxford Vessel Launched, England.—Messrs. William Doxford and Sons, Ltd., Sunderland, launched another of the Doxford standard vessels for the Moor Line, Ltd., managed by Messrs. Walter Runciman and Company, Ltd. Dimensions, 450 feet by 54 feet by 37 feet; closed shelter deck type, 10,800 tons on 28¼ feet draft; 12 knots trial speed. Vessel was named Castlemoor.

Exceeds Contract Speed, Canada.—New Canadian Pacific turbine steamer Empress of Canada, recently built on the Clyde by Fairfield Shipbuilding and Engineering Company at cost of over two millions sterling, completed her first trip across the Pacific without a hitch. She averaged 19.75 knots, engines developing 21,000 horsepower and passed previous record on the eastbound trip across the Pacific by 8½ hours.

Conversion of German Warship.—The Ægir, recently placed in commission, was converted to motor cargo-carrying ship. Last year the Odin was similarly made over and has been engaged in conveying locomotive and other material from Germany to Russia. The decks of the Ægir were cut out and steam machinery was replaced by two Benz-Diesel engines, each 350 horsepower. The vessel can carry twelve locomotives and tenders, former being placed on removable rails on deck.

Contract for Three New Vessels, England.—The United Fruit Company has placed contracts for the construction of three large passenger and cargo steamers, to ply between the Caribbean and Boston, with Cammell, Laird & Co., Ltd., of Birkenhead, England. The ships are to be finished in about a year. They will be 325 feet long, 48 feet breadth of beam and 31.9 feet depth of hold; equipped with four 750-horsepower Diesel electric engines. The British Thompson, Houston Company, an associate company of the General Electric, will furnish the electric drive.

Steel Screw Hopper Barge, England.—Steel screw hopper barge No. 18, first of three vessels which the Monmouth Shipbuilding Company, Ltd., Chepstow, are building for Port of London Authority, was launched recently. Vessel is of single-deck type, with raised forecastle and large hopper placed amidships for carrying dredgings. Dimensions are: Length between perpendiculars 215 feet, breadth molded 35 feet 6 inches, depth molded 19 feet 3 inches, mean draft 16 feet. Propelling machinery consists of one set of triple expansion surface condensing engines, capable of propelling vessel at speed of 10 knots.

Tanker Launched, England.—Sir W. G. Armstrong, Whitworth and Company, Ltd., launched from their Armstrong yard the steel screw tanker Amsterdam, built to order of American Petroleum Company, Rotterdam. Principal dimensions of vessel are: Length overall 455 feet, length between perpendiculars 440 feet, breadth extreme 57 feet 6 inches, depth molded to upper deck 33 feet 11 inches. She will be fitted with triple expansion machinery, steam being supplied by three boilers working at 180 pounds pressure and capable of propelling the vessel, when loaded with 10,450 tons, at speed of about 11 knots on mean draught of 26 feet 3 inches.

German Shipbuilding Figures.—Since the beginning of March, 1922, 19 large steamers representing a total of more than 100,000 tons have been launched from German shipyards for account of German navigation companies. Since the same date the Germans have purchased abroad about 35,000 tons. The amount of steamers actually under construction at German yards represent a total of more than 300,000 tons. The tonnage built in the year 1920 was about 500,000, exceeding by about 40,000 tons the total construction of the year 1913. The present productive capacity of the German shipbuilding yards is estimated to be at least 700,000 tons per annum.

STEAMSHIP INTERESTS

The shipping department of the Hugo Stinnes interests plans to open in October a new line from Hamburg to Singapore, Shanghai and Yokohama.

A. Miller McDougal, shipbuilder, has announced plans to establish next spring a refrigerator and package service with a fleet of modern freighters plying between Duluth and the Atlantic.

At the request of Portland shippers, the Shipping Board has allocated three additional vessels to the Columbia Pacific Shipping Company for Trans-Pacific service. This will give the concern two sailings a month to the Orient from Portland.

With the sailing of the *City of Los Angeles* from Los Angeles on September 9, the Los Angeles Steamship Company will inaugurate a passenger and freight service to Honolulu. The *City of Los Angeles* drydocked at Los Angeles Shipbuilding Company to undergo reconditioning. Upon the arrival of the *City of Honolulu*, from New York, at Los Angeles, the ship went into the same yards to be overhauled. The *City of Honolulu* will sail on September 23, according to present schedule.

The yacht *Cynthia*, designed by Cox and Stevens and built by the Todd Shipyards Corporation, passed successful trials. The vessel is a twin screw, Diesel engined yacht, 129 feet over all in length, 26 feet beam, 6 feet 6 inches draft. Her main propelling machinery consists of two Diesel type six-cylinder four-cycle Winton engines, each developing 225 brake horsepower. She has a cruising radius of 4,000 miles and is designed for a speed of twelve knots. The yacht is owned by Commodore Merill B. Mills, of Detroit.

The United American Lines, managing agents for the American Hawaiian Steamship Company, have extended their service from the North Atlantic to the Pacific Coast to include the port of Baltimore and have inaugurated a new service to the Pacific Coast from Mobile and New Orleans. The Baltimore service is fortnightly and the Gulf service, monthly. These services are in addition to the weekly sailings already maintained by the company to the West Coast from New York, Boston and Philadelphia. The expansion of this service to include Baltimore, Mobile, and New Orleans, involves the addition of nine steamers. The United American Line opened a branch office at Baltimore in the Maryland Casualty Building on August 14.

BUSINESS NOTES

The Johns-Pratt Company, Hartford, Conn., manufacturers of Noark fuses and protective devices, Vulcabeston packing and insulation and Johns-Pratt molded products, announces the establishment of a New York office at 41 East 42nd Street, New York.

Scheid Engineering Corporation, 90 West Street, New York City, has been appointed metropolitan and export representative for the Franklin Moore Company, Winsted, Connecticut, manufacturers of Material Handling Machinery for industrial plants.

Announcement has been made of the consolidation of the Foamite Firefoam Company, with general offices at 151 Fifth Avenue, New York, and O. J. Childs Company, Inc., of Utica, N. Y., in a program uniting these important fire protection interests under a new and complete service organization. At a meeting of stockholders recently it was decided that the company will hereafter be known as "Foamite-Childs Corporation" and the following officers were elected: Mr. W. J. Childs, president of the Childs corporation, president; F. M. Watters, vice-president; E. Janeway, secretary; and F. J. Maginniss, treasurer. Mr. James C. Patterson will continue as a director in full charge of sales. There will be no change in the sales policies of the consolidating companies. The executive offices will be located at Utica, N. Y.

TRADE PUBLICATIONS

Towing Machinery.—A description, with photographs, drawings and technical data, is given in a bulletin by the American Engineering Company, dealing with its automatic steam towing machine. Detailed information on the operation of the machine is given.

Lewis Iron.—The Penn Iron & Steel Company, of Creighton, Pa., has issued an interesting booklet on the manufacture of iron and iron products. Considerable details are also given regarding the Lewis special staybolt iron, engine bolt iron, chain iron, drill staybolts and U. S. Navy iron. Tables are shown giving the weight per foot of round and square iron.

Standard Seamess Tubes.—In No. 1, of a series of brochures published by the Standard Seamless Tube Company, of Pittsburgh, Pa., the bloom was followed through various steps to finished chipped billets. The second bulletin, showing the tube mill operations including the piercing of steel billets, has been distributed and will be followed by a third issue showing the Cold Draw Department.

Metals Coating.—A series of photographic reproductions with descriptive matter has been published by the Metals Coating Company of America, Philadelphia, Pa., which present the adaptability of commercial requirements of the Schoop metal coating process. As a protection against high temperatures, it is set forth that, by spraying with aluminum, oxidization and scaling in grate bars and similar pieces is retarded and clinkers are prevented from adhering. It is also claimed that the Schoop metal spraying process can be successfully applied to distributors and automatic stokers, condenser tubes, pyrometer couple tubes, boiler tube cleaning equipment, valves, pistons, explosion chambers of internal combustion engines, etc.

MARINE SOCIETIES

WE GUARANTEE that of this issue, 5,250 copies were printed; that of these copies 3,878 were mailed to regular paid subscribers, 214 were provided for counter and news company sales, 237 were mailed to advertisers, 43 were mailed to employees and correspondents and 878 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 54,750—an average of 5,475 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Action Scheduled for November

THAT the shipping bill will come up for action in the House in November and in the Senate in December is the belief of the majority of the Congressmen. The opponents of the subsidy know full well that to delay action on this measure in the House until the short session, when that body's time will be fully occupied with appropriation bills, would delay consideration of the proposed shipping legislation until the next Congress which begins in March. In the meantime they hope that the elections in November will result in a depletion of the Administration's majority and that a sufficient number of new members who are opposed to Government aid to shipping will be obtained to kill the bill for good and all.

It is not reasonable to suppose, however, that the Administration after causing one of the most complete studies that has ever been attempted on any subject made by the very best experts on shipping, and after incorporating the facts and findings of these experts in the pending legislation and putting up the splendid fight for an American merchant marine that it has, will sit quietly by and allow the opponents of the bill to have their way without a struggle.

It is, therefore, with a great deal of satisfaction that we note a quotation of Representative Mondell, Republican floor leader in the House, in a bulletin of the National Merchant Marine Association which is as follows: "The shipping bill is not dead by any means. We will follow the President's suggestion and postpone action on it just for the present. I believe that it will be taken up in November and may even be passed before the December short session."

The subsidy opponents will also shortly find out that the American merchant marine has a good many staunch supporters among the Democrats. Note the way the National Merchant Marine Association, of which Senator Joseph E. Ransdell, a Democrat, is president, figure it out. "The President has agreed to a postponement until shortly after election, presumably until Monday, November 13, and the few weeks remaining between then and the opening of the December session will supply sufficient additional time for the shipping bill to make its passage practically assured. Under the House rules speedy action can easily be secured and the bill passed before the beginning of the December session, while the Senate will have probably about six weeks in which to act before the annual appropriation bills will have come through the House to the upper branch."

Bearing in mind the extraordinarily difficult industrial situation to which the President has been compelled to devote practically his whole time during the summer, it is a reasonable belief that he suggested the postponement of action to November in order that he might be free to champion to the limit the cause of American shipping. When the time for action arrives and the complex problems now confronting the Administration and the supporters of the subsidy bill are solved, then, the foreign shipping interests and their followers will learn that America is determined to support its merchant marine by the only comprehensive plan that has been advanced by our shipping experts.

American Marine Week

AMERICAN Marine Week, which will be celebrated at the Grand Central Palace, New York City, from November 4 to 11, will have a far reaching effect on the destiny of our merchant marine. The benefits that can be secured for American shipping through the cooperative and united action of the principal maritime organizations cannot be exaggerated. With the marine field acting as a unit, it is bound to have a strong influence on the passage of the pending shipping legislation and, with the widespread publicity that undoubtedly will be given to the papers and addresses, presented by prominent men at the various meetings, there cannot fail to be a revival of interest in our merchant marine in the public mind. When the

general public realizes that the prosperity of our country depends on shipping our surplus products to foreign markets the future of American vessels will be assured.

American Marine Week means much to the marine field in general but it will mean much more to every man who is fortunate enough to be able to attend. The Marine Exposition will be a brilliant display of everything that is new and interesting to the marine profession. Models of ships and inventions, full size specimens of equipment, fittings and the products that enter into the construction of vessels, naval exhibits, life saving devices and many other items may be examined and studied at close range. No one who desires to keep up to date can afford to miss such an opportunity.

In addition to this, professional men will have an opportunity to hear technical papers that will be read before the annual convention of the Society of Naval Architects and Marine Engineers. These papers and the discussion of them by members of the society are published all over the world. What an opportunity not only to hear the best that America can give to the science of naval architecture and marine engineering but also to see and make the acquaintance of the leading specialists in marine design!

But even this is not all, for at the convention of the American Marine Association addresses on maritime subjects will be delivered by prominent Government officials and leading members of the numerous organizations participating in American Marine Week. So it will be the privilege of those who attend the conventions to get a composite picture of the problems of the entire marine field and its allied industries.

Finally, one of the greatest reasons why every one who can possibly attend should do so is that the entire week offers opportunities for making acquaintances and meeting old friends. There is no other occasion during the whole year when the entire marine field gets together. The intimate business and social intercourse between shipowners, shipbuilders and manufacturers of marine equipment from all over the country is not only of great benefit to the industry as a whole but it is also of great personal advantage to every one who has the privilege of attending.

The Agamemnon and Mount Vernon

According to a newspaper interview with Commissioner Frederick I. Thompson of the Shipping Board on his recent arrival from Europe, that official will immediately recommend that the liners *Agamemnon* and *Mt. Vernon* be reconditioned and put into service. As an indication of the necessity of putting these ships in commission, Mr. Thompson reported that the *George Washington* could have taken 200 additional passengers on her return trip, if there had been room for them.

Officials of the United States Lines have made careful studies of the possibilities of these vessels and their estimates show that very favorable returns could be earned on the cost of their repair. The *George Washington* and *America* are making money and there is a growing sentiment both here and abroad in favor of traveling on the ships of the United States Lines. The *Leviathan* will be a great advertisement for our merchant marine and practically all Americans who travel to Europe will want to say that they made at least one trip on this famous vessel which, when completed, will be second to no ship afloat.

On the other hand what is to be done with the *Agamemnon* and *Mt. Vernon*, if they are not reconditioned? Are they to be allowed to rust away at their docks at Hoboken and Boston or are they to be sold to foreign interests who will recondition them and put them into competition with our own vessels? Is the *Leviathan* to be the only 23-knot liner in the American transatlantic service until new ships are built? Who is going to be responsible, if that vessel builds up a sort of one way express passenger service from which foreign lines receive from one-half to two-thirds of the benefit?

A Standard Bill of Lading

It is generally recognized that there is an urgent necessity for a clear codification of the rights and liabilities which arise between carriers and shippers upon bills of lading used for ocean shipments. The Hague Rules, 1921, which are the result of voluntary action and bargaining between vessel owners and shippers, were drawn up under the guidance of the International Law Association and they contain, in such terms that business men all over the world who are engaged in overseas trade can understand them, a set of rules that has received the endorsement of most foreign commercial organizations and the Chamber of Commerce of the United States.

To quote Mr. A. D. Mearns, chairman of the Liverpool Steamship Owners' Association: "I am satisfied that the drafting as it stands will serve in the 999 transactions of which the lawyers never hear. I should have thought that it would serve even in the one case out of the 1,000 that comes before the law courts, if the lawyers are only content to interpret the rules as they are understood by the traders and the shipowners, and to forget the thousands of cases that have been collected, discussed and criticised by Lord Justice Scrutton and Mr. Carver."

We are, therefore, glad to learn that the United States will send representatives to take part in a discussion of a revised form of the Hague Rules which will be under consideration by the Comite Maritime in London on October 9-11. The results of this consideration by the Comite Maritime will be brought before the International Maritime Conference which is to meet in Brussels the latter part of October. This conference has been called by the King of Belgium and the United States will be represented there by official delegates appointed by the President.

In order that the delegates from the United States might have the benefit of the views of all interested parties, the Shipping Board held public hearings in Washington on September 20-21 which were attended by representatives of shipowners, shippers and underwriters. The Shipping Board is to be commended on securing American representation at the coming International Conference and also for giving our delegates a line on the opinions of our business men through a public hearing. It will be noted from the article on page 643 that there is not an American signature on the recent report of the International Conference on Safety of Life at Sea.

The 1,000-Foot Ships

CHAIRMAN LASKER'S statement, that a $30,000,000 company has been projected which will construct two mammoth liners of 1,000 feet length and of 70,000 gross tons, providing the pending shipping legislation is passed, has caused considerable comment. Although Mr. Lasker asserted that the names of the members of this proposed company are household words, no publication, at this writing, has succeeded in obtaining anything but denials of participation from the prominent men who would be considered most likely to engage in a shipping venture. But, as it is inconceivable that Mr. Lasker would make such a statement without good reason to believe that these vessels would be actually built providing reasonable national protection is secured for our shipping, we can account for our lack of knowledge of who the principals really are by the fact that financial affairs are usually consummated before they are made public.

There is nothing new about a proposal to build vessels of 1,000 feet in length. It will be remembered that there was considerable publicity given to such a project about three years ago and at least the preliminary plans for two 1,000-foot liners were said to have been actually made by the Gibbs Brothers. Perhaps, if President Wilson had not requested the International Mercantile Marine Company not to dispose of its vessels flying the British flag to an English syndicate, these ships would have been under construction or completed today. Optimism prevailed in shipping circles in 1919. Prominent shipowners predicted that the shipyards would be busy for years and it was easier to obtain $200 a ton for a vessel then than it is to get $30 now.

Since then, however, the White Star Line and the Cunard Line have each placed three monster greyhounds on the North Atlantic service and these big ships are not only paying their own way but also making up any deficits of the smaller vessels. It is a fact that accommodations on the larger vessels are always in demand in spite of the excess fare and when a vessel is carrying between 1,000 and 1,200 first and second class passengers each way it is not difficult to believe even if we did not know that they are clearing as much as a quarter of a million dollars on each round trip.

Now as the great majority of first and second class passengers are American citizens, there is every reason to believe that American ships having equal or greater speed and luxurious appointments would secure their share of the trade and, if the Government, as it is proposed in the shipping bill, grants sufficient compensation to make up the difference in cost of construction and operation over that of foreign ships, what is there strange about America adopting the German policy of going their English rivals one better?

The shipping bill is framed to encourage the construction of vessels that are most needed not only from a commercial but also from a naval standpoint. The 1,000-foot ships would be a most important addition to our naval reserve and, for this reason alone, they ought and probably would be entitled to a maximum loan at 2 percent interest from the Construction Loan Fund, if their plans were approved. The subsidy for such vessels on account of speed and tonnage would exceed that for any other class of ships.

Suppose to all these considerations were added the net work of soliciting agencies and ticket offices of the Pennsylvania Railroad. Suppose that railroad should sail such vessels from Montauk Point, running boat trains from New York over its subsidiary the Long Island Railroad and in so doing reduce the time of transatlantic passage by 7 hours. The Canadian Pacific is making a success of its passenger steamship lines on both the Atlantic and Pacific. If they can do this in Canada, why not in the United States?

Motorship Makes Remarkable Record

ACCORDING to a letter sent to Admiral Benson from Captain R. H. Wright, master of the motorship *William Penn,* a carefully made record of all mileage covered, including sea voyages, rivers, canals and harbor movements, shows that this motorship traveled a total distance of 44,781 nautical miles in the year starting August 7, 1921, and ending August 7, 1922.

Captain Wright also stated that "during the whole of this period she has never made an involuntary stop, she has suffered no breakdown of any sort and her repair bill for actual repairs of all sorts is less than $100, United States currency.

"Her average speed for the period hereinbefore stated was 11.16 knots; her approximate fuel consumption has been 13 tons per diem, while her average consumption per diem in port has approximated 64 gallons."

The *William Penn* was originally designed for a steam installation but before completion it was decided to fit her with Burmeister and Wain type Diesel engines which was done at the yard of the William Cramp and Sons' Ship and Engine Building Company. She is a twin screw vessel of 17,000 tons displacement, having a deadweight carrying capacity of 12,375 tons and her engines are rated at 4,250 horsepower.

Her record for the year stated above is worthy of note for the number of nautical miles covered, the absence of a breakdown of any nature, the small cost of voyage repairs and the fuel consumption. Allowing due credit to her officers and particularly to Chief Engineer Olsen who showed the writer one of the cleanest and most shipshape looking engine rooms that he has ever seen when the *William Penn* was in New York harbor after her first voyage around the world, the performance of this vessel should have a decided influence on future machinery installations.

More than this, it should be a real inducement to shipowners to purchase a number of the tied-up Shipping Board vessels which can be obtained at very low figures and convert them to motorships. When a vessel's machinery runs a whole year without an involuntary stop, there can be no question of reliability; when the voyage repairs for that period are less than $100, the quality of the machinery cannot be excelled, but when you can operate a ship of that size on 13 tons of fuel per diem, when it would require at least 50 tons with a steam installation, then it is either time for shipowners to start acquiring motorships or for Diesel engine manufacturers to reduce the price of production to a point where the first cost figures do not require too long a time to make up the difference in cost of operation.

Ship Subsidy Is a Retaining Fee for National Defense

The "Merchant Marine Fund," Provided in the Shipping Bill, Should Be Called the "National Defense Retaining Fund"

By "Old Scotch"

IN the matter of national defense on the seas, many Americans, since the Washington Conference on Disarmament, have lulled themselves into a spirit of tranquility because by virtue of the 5-5-3 treaty with Great Britain and Japan we are on an equality with the world's greatest naval power. But is such the fact? Who among all of the people in the country fails to remember the terrific havoc wrought to the allied shipping by such raiders as the *Moewe* and *Eitel Frederick* and half a dozen more like them. Yet the German surface navy was supposed to be hermetically bottled up back of the guns of Heligoland and other impregnably fortified places. This little retrospection is simply to recall that merchant vessels are a very important means for sea strife, not to mention their value for carrying supplies, fuel and men to keep fighting vessels at sea, and to carry on military operations on foreign shores. Hence without a merchant marine, our 5-5-3 tranquility is somewhat of a myth.

Counting all merchant ships of 13 knots and upwards as available and necessary adjuncts to the regular fighting vessels we find the following comparisons between Great Britain and the United States:

Vessels Over 3,000 Tons	Great Britain	United States
13 to 18 knots speed..........	548	144
Over 18 knots speed..........	44	6

The above figures represent relative sizes of the two merchant marines for purposes of national defense as they were on January 1, 1922. If conditions continue as they are today, even our inferior proportion of the vessels quoted cannot be maintained, as many of our ships are idle and will rapidly depreciate in both physical and financial value. Suffice it to say that our tranquility regarding the 5-5 ratio is very evidently a myth, and that unless efforts are made by the Government to maintain the merchant fleet we now have, and to add a sufficient number of diversified types of craft to round out a sufficient and reliable supporting fleet of merchant vessels, our feeling of national security on the seas may at any time suffer a decided shock and rude awakening.

Enactment of Subsidy Bill Absolutely Necessary

The pending merchant marine bill, if enacted, is absolutely necessary to save us from such a shock, and attention is drawn to our palpable unpreparedness for national defense, so far as the necessary fleet of merchant ships is concerned, to emphasize the suggestion herein made, that this phase of the pending bill is of equal importance to the needs of maintaining a merchant fleet for our commercial interest.

The so-called "Subsidy Bill," has now been before the public for nearly a year, and such opposition as has been raised in the public press, has almost entirely been centered on the direct payment of money to shipowners, to enable them to overcome the handicap of higher initial costs and higher maintenance charges, when compared with similar merchant vessels operated by our foreign rivals.

People familiar with shipping, and with the terms of the pending bill, know that the object of this direct compensation is "To promote the growth of the foreign commerce of the United States," and "To contribute to the national defense," but to the average reader who gains his limited knowledge of maritime affairs from headlines in the daily press, the impression prevails that the entire object of the bill is to aid the owners of merchant ships to carry on their own business on the seas. The money to be raised for this purpose is called in the bill the "Merchant Marine Fund," which still further convinces the average citizen that his superficial estimate is correct.

Direct Subsidies Are for National Defense

As the maintenance of a merchant fleet in private hands is so distinctly a great national asset for purposes of the common defense on the seas, this direct payment to private shipowners should be made with the distinct understanding that it is a "Retaining Fee" from the Government to the private shipowner for having the first claim on his ships for purposes of national defense. The money with which it is paid should be taken from the "National Defense Retaining Fund," and it should be termed such in the pending bill. This should be stressed in all debates by the friends of the measure, and in all references in the public press, in order that the public may get away from the idea that shipowners are alone to benefit from the proposed legislation.

The idea of a "retaining fee" is now well established in our daily life, and it is not considered in the nature of a gift by any means. The first claim on services in emergencies which may arise is a "quid pro quo" generally recognized.

What the "National Defense Retaining Fund" Will Do

It is an indisputable fact that we must maintain a large merchant marine as a complement to naval preparedness in the defense of our country. With that as a basis, if we do not maintain such a fleet by means of the pending shipping bill, the only alternative is that the Government must build and maintain such a fleet of vessels as a part of its naval fleet. On the basis of the Retaining Fund idea, with ships in private ownership, this can be accomplished for \$30,000,000 per annum; in the event of the necessary merchant fleet being maintained under naval auspices and solely for defense purposes, the total expense would be enormous, and possibly would cost as much as the fighting ships of the regular navy as now maintained.

Without some such encouragement as now contemplated in the shipping bill, it needs no seer to predict that in a very short time our merchant marine would rapidly degenerate to its pre-war condition, where the number of efficient ships engaged in foreign trade could be counted on the fingers of both hands. Modern wars with our up-to-date systems of communication and transportation come very suddenly. No one expects or wants to see any more warfare in this generation, but the unexpected is what usually happens. A merchant fleet for use in the national defense cannot be improvised, built nor bought in an emergency. Our sins of omission in the matter of having merchant ships cost us more than three billions of dollars in the World War. In the light of so recent a catastrophe, are we again going to be caught in such a trap?

Of course there is bound to be captious criticism of the idea of paying retaining fees to shipowners for the first use

of ships in the time of national emergency. The arguments will be advanced that any one possessing equipment necessary or useful for war purposes should be the recipients of retaining fees for possible emergency use by the Government. The owners of large numbers of motor trucks, for example, might claim that as such vehicles are highly essential in the prosecution of a war, they should be recompensed for holding them in readiness and fit for use in times of strife. The answer to such claims is simple, as ships are in a class by themelves, in that they can be owned by American companies, and for purposes of economical operation may be sailed under alien flags.

It might be claimed that we can pass a law forbidding the transfer of flag on any ship now documented in this country. Very true, but how long would such procedure insure the operation of an efficient merchant fleet for naval purposes. All replacements of existing ships could be placed under foreign flags, and in a very brief time we would find American flag ships had disappeared from the seas; then where would we get the ships necessary for national defense?

The great fleet of merchant ships on the Lakes is not only unsuitable for ocean service, but unobtainable on account of canal restrictions. Our coastwise fleet is insufficient in number, type and size for the needs of the country in war times. It is a very recent date that a large exporting concern in this country found it cheaper to charter foreign vessels to transport its goods to Far Eastern ports than to use its own vessels under the American flag. Consequently they were tied up at the wharves. This would probably occur again, unless Congress provides some such relief as is contemplated by existing bills in Congress.

Prospects for Shipping Legislation Grow Brighter

Fortunately for everyone concerned the prospects for legislative relief are now more roseate than they were. President Harding and our Congressional leaders are determined to force action, even to the extent of calling on extra session shortly after the Fall elections. Rail and coal strikes have for a time taken the public attention away from what has been termed the most important question now before the American people.

The bonus for soldiers, and the tariff for protection of our industries, are very important for the time being, but they pale into insignificance when compared with the dire necessity for providing a lasting system for maintaining our merchant shipping, both for our commercial needs and for the defense of our country. The latter must not be subordinated in the popular mind, and it behooves Congress and the public as well to consider the expenditures proposed of equal importance for both of the benefits to be derived—commercial independence on the seas and adequate national protection.

American Marine Week Comes at Psychological Time

Cooperative Efforts of Eighteen Maritime Associations Will Exert Powerful Influence on Pending Shipping Legislation

Naval Architects to Hold Convention in Auditorium of Grand Central Palace Reduced Rail Fares for Exposition Delegates Secured

The Marine Exposition and the conventions and meetings of the maritime associations which will be held at the Grand Central Palace, New York City, November 4-11, coming as they do just before the shipping bill is taken up in Congress, are bound to have a very favorable effect on securing reasonable National protection for our shipping.

Whether taking it from the standpoint of designing, building or operating, the American maritime industry is now fighting with its back against the wall. But even as we were not too late in entering the World War so it is now not too late for Congress to grant protection to an industry that is becoming more and more of vital importance to the prosperity and safety of the country.

Therefore, no one who can possibly get away from his work should fail to attend and support this united endeavor of the marine industry. The personal benefit of inspecting the latest marine equipment and renewing and making new acquaintances will be great but the value of a record breaking attendance at this big gathering will, to the industry as a whole, be of greater value.

Naval Architects' Meeting

The Thirtieth Annual Convention of the Society of Naval Architects and Marine Engineers will be held in the Auditorium of the Grand Central Palace, Lexington Avenue and 46th Street, Wednesday and Thursday, November 8 and 9, 1922. Professional sessions will begin at 10 A. M. each day.

In order to extend acquaintanceships, a reception committee will be appointed. New members or members who have not attended previous meetings should get in touch with the reception committee on arrival at the meeting.

Arrangements have been made to register all members upon entrance at the Grand Central Palace. The data will be on hand at all times at the announcement desk and will be of great service to any of the members who desire to keep in touch with each other during the convention period.

Prior to the general meeting, the Council of the Society will meet at 3 P. M. Tuesday, November 7, in room 1101 of the Engineering Societies Building, 29 West 39th Street, New York, N. Y.

Program of Professional Sessions

Below is given a list of papers to be read. Members may obtain advance copies of the papers by applying to the Society headquarters, 29 West 39th St., New York, N. Y. In presenting papers, each author will be limited to twenty minutes for the reading of an abstract of the paper; this time to include the showing of lantern slides, if any are to be used. Remarks in discussion of papers will be limited to ten minutes for delivery, including the showing of lantern slides.

Wednesday, November 8

"Automatic Steering." By Elmer A. Sperry.

"Details of Naval Design from Jutland." By Commander Herbert S. Howard, C.C., U.S.N.

"The Application of Dyson's Method to Propellers of Ocean-Going Merchant Vessels." By Edwin A. Stevens, Jr.

"Stresses on Vessels of The Great Lakes Due to Waves of Varying Lengths and Heights." By Professor H. C. Sadler and Professor Anders Lindblad.

"A Study of the Wake of Certain Models by Means of a Current Meter." By Professor Edward M. Bragg.

"Some Experiments on Propeller Position and Propulsive Efficiency." By Rear Admiral D. W. Taylor, CC., U.S.N.

Thursday, November 9

"Efficiency in the Operation of Steamships." By Captain Daniel A. J. Sullivan.

"A Sixteen Hundred and Fifty Horsepower Gasoline Fire Boat." By Arthur D. Stevens.

"The Longitudinal Strength of Rigid Airships." By Professor William Hovgaard.

"Machinery and Trials of the Passenger Ships—American Legion Class." By Robert Warriner.

"Standardization as Affecting the Shipbuilding Industry in the United States." By Ernest H. Rigg.

"The Selection of the Best Kind of Propelling Machinery." By James L. Ackerson.

Naval Architects and Marine Engineers' Banquet

The annual banquet will be held in the Grand Ball Room of the Waldorf-Astoria, 34th Street and Fifth Avenue, New York, on Thursday evening, November 9, at 7.30 P. M. Immediately preceding the banquet there will be a reception beginning at 7.00 P. M. All members and their guests are cordially invited.

Seats for the banquet will be $6.00 each. Each application for tables or seats should be accompanied by remittance and made by letter so as to reach the secretary on or before November 2. Telephone requests must be confirmed by letter.

Members submitting applications for reserved tables should state the number in their party who are not members of the Society. Applications for reservations for more than three tables (30 seats) will, by direction of the executive committee, require special approval, which approval can only be given in the discretion of the committee, after the reasonable requirements of other members of the Society have been met.

Reduced Rail Fares

Another announcement of interest and importance is the statement that the Trunk Lines Association has granted a reduced fare rate for all delegates attending any of the meetings in conjunction with the American Marine Association and Marine Week. Persons coming to New York will purchase full priced tickets at their point of departure and will request an identification convention certificate. Upon arrival at the Exposition, the certificates will be validated by the chairman of the Transportation Committee, John A. Hense. Upon returning, holders of the certificates may present them at any ticket window and receive a ticket at half fare, or a saving of 25 percent.

The transportation committee has also arranged adequate facilities in the way of a ticket office, reservation bureau, etc., at the show, and will also maintain a New York City sightseeing bureau where visiting delegates and strangers in the city may arrange for tours.

List of Other Attractions

A partial list of other attractions, maritime organizations that have so far signified their intention of taking part in the Exposition, and the manner in which they will participate, is given in a report of the Liaison Committee of the American Marine Association, as follows:

1. The Shipping Board—by an exhibit. Plans are under way to secure addresses from Chairman Lasker and other commissioners on the shipping bill or other projects on which the board is working.

2. The Navy Department—by an exhibit and also by addresses of leading naval officials.

3. The Department of Commerce—will stage a combined exhibit of their various marine bureaus which will occupy about 2,000 square feet of floor space. The heads of several bureaus of the Department of Commerce have promised to deliver addresses during the week.

4. The Society of Naval Architects and Marine Engineers—will hold its annual convention *November* 8 *and* 9 in the auditorium of the Grand Central Palace, and its annual banquet on the evening of *November* 9 at the Waldorf Astoria.

5. The Maritime Association of the Port of New York—by an exhibit. They have also appointed Fred B. Dalzell, Jr., chairman of a committee to co-operate in every possible way with the maritime organizations taking part in American Marine Week. Mr. Dalzell has guaranteed that speakers from this organization will be available.

6. The American Steamship Owners' Association—will hold its quarterly meeting on Monday, November 6. Mr. Marvin, vice-president of the organization, assures us that speakers will be available and he is endeavoring to secure attendance at the Exposition of their official technical committee and the members of their organization.

7. New York Tow Boat Exchange—This organization will take part through an official committee and will also furnish a moving picture film of tow boating in New York Harbor.

8. Ocean Officers' Conference (composed of captains, mates, engineers and radio telegraphers)—This organization has agreed to hold a smoker in the auditorium of the Grand Central Palace.

9. Atlantic Coast Shipbuilders' Association—J. L. Ackerson, president, states that the organization will be represented at least by an official committee and that he will try to give us still greater co-operation. Plans are under way to secure speakers from this organization during the week.

10. American Bureau of Shipping—will hold meetings of the board of managers and will hold meetings of their technical committees on both naval architecture and marine engineering.

11. National Merchant Marine Association—We have received letters from this organization stating that they would be glad to co-operate with us and have asked for suggestions as to the best way to do this.

12. American Society of Marine Designers—will be represented by a booth at the exposition and will also be represented by the executive committee of the national organization. This society will not hold a convention this year.

13. The Neptune Association—Captain Milliken, secretary-treasurer, has promised us that he will support American Marine week in any way he can.

14. The Port of New York Authority—will exhibit at the Exposition and co-operate in American Marine Week.

15. Mississippi Valley Association—Plans for this association are under way.

16. Los Angeles Chamber of Commerce—has the matter of exhibiting under consideration.

17. San Francisco Chamber of Commerce—D. K. Grady, Director of Foreign and Domestic Trade Department, is now working on the best way for the San Francisco Chamber of Commerce to cooperate.

18. The American Society of Naval Engineers will have a booth at the Marine Exposition. They will have at their booth bound volumes of their transactions and other interesting material.

The interest in American Marine Week that has been shown by the above organizations proves that the idea of one annual get-together week at the same time and in conjunction with the Marine Exposition has taken firm root. It is particularly fortunate that such extensive cooperation has been extended this year because it will not only assure a splendid and profitable time to all who attend but it will also exert a great influence upon the future of our merchant marine.

What the Shipping Bill Is and Does

By Winthrop L. Marvin*

It should be emphasized that it is now costing about $50,000,000 *a year to maintain* 450 *steamers of the Shipping Board. The new shipping bill will aid and encourage, not only these government-owned steamers when they have passed into private hands, but also American private shipping in the foreign trade, now without any assistance whatsoever from the United States. In other words, an expenditure of an amount less than that which the Shipping Board is now paying for the maintenance of its own fleet will, in this bill, cover the entire American merchant marine in overseas commerce.*

JUST what the new shipping bill is and does—just how far it goes in bestowing National aid on the merchant marine—what its cost is and what its duration—all this is well worth pointing out from amongst the more than half a hundred legal pages in which its various terms are meticulously expressed.

In the first place, in its very first paragraph, the new bill broadens the first Jones law, the Merchant Marine Act of 1920, to facilitate the quick sale of the government-owned ships to private capital and enterprise. There can be no shadow of a doubt that all but a few scattering members of both political parties in this country very strongly desire a privately-owned and controlled merchant marine. Advocates of a permanent government-owned shipping are about as scarce in the United States as genuine specimens of the Russian Bolsheviki.

Public opinion emphatically approves the initial provision of the new bill directing the Shipping Board to sell all the government tonnage to "citizens of the United States, except as provided in section 6" of the Act of 1920. This exception permits the sale to foreigners of vessels that are not sought by American purchasers. Under this provision there are now occasional sales to aliens, by authority of the Shipping Board.

In the Merchant Marine Act of 1920, the Board in disposing of its tonnage, is constrained to give heed to the previous prices and replacement costs of ships. Strictly interpreted, that might prove a veto on the disposal for $30 a deadweight ton of cargo craft that in the war emergency had cost $200 or more a ton. Such impossible restrictions are swept away in the present bill, with general approval—for few men would wish to retain an unworkable plan, which would block every effort of the Government to extricate itself from the shipping business. Even those Democrats of the House Committee on Merchant Marine and Fisheries who signed the minority report against the Shipping bill as a whole are careful to protest that "we are opposed to permanent government ownership or operation of merchant ships."

Sale of Ships

Sales of ships, under the proposed bill, must be by "public or private competitive sale after appraisal and due advertisement"—but the Board is empowered to waive advertisement and competitive sale by affirmative vote of at least five of its seven members, making a public record of the reasons for their action. Complete payment of purchase price and interest must be made within 15 years. Interest, payable at least annually, shall be at a rate of not less than 4 percent, and payments of the principal shall be so arranged as to cover at any time depreciation of a vessel—unless the Board waives this requirement on the giving of adequate security by the purchasers. Thus, with the added restrictions and limitations of the law of 1920, there are abundant safeguards of the Government as a seller.

Another new clause amendatory of the Merchant Marine Act of 1920 is a provision in section 2 of the new bill reserving for at least two years the purchase of lines now locally controlled to the local companies now operating these services, with a view to "discouraging monopoly in the American merchant marine." This makes it probable that the new companies organized at South Atlantic and Gulf ports to operate Shipping Board routes will remain in control of those routes under the new policy of cessation of allocation, with National aid to private ownership and enterprise. This is a provision that strongly commends the bill to the favor of the South and Southwest.

In the Merchant Marine Act of 1920, there was authority for the expenditure of $25,000,000 a year for 5 years as a revolving loan fund, at an interest rate of not less than 2 percent, for the encouragement of construction in American yards of particularly necessary types of ships—fast mail steamers of the naval reserve, Diesel-engined cargo craft, etc. This is an expedient that many foreign governments have successfully employed—a notable case was the British government loan for the building of the *Mauretania* and *Lusitania.* In the Shipping bill the authority covers the construction and equipment of special ships, the Government to be protected by a first lien on the vessel. All loans must be repaid within 15 years.

It is to be borne in mind that this is not a gift fund but a revolving loan fund to come back into the Treasury.

Income Tax Deductions

These are the amendments to the Merchant Marine Act of 1920. In section 201 of the new Shipping bill is a very important plan of indirect aid to the merchant marine, amending the Revenue Act of 1921, so that for 8 years from 1921, a shipowner shall be allowed, as a deduction in computing net income, "an amount which bears the same ratio to his net income during the taxable year attributable to the operations of such vessel as his gross income attributable to the foreign operations of such vessel bears to his entire gross income attributable to the operations of such vessel." But this deduction is conditional upon the amount of the deduction being set aside for the building of new ships in private American shipyards. So also any taxable gain on the sale of any ship launched prior to January 1, 1914, may be counted as a deduction if the entire proceeds of the sale are devoted to new construction, or if less than this amount the deduction shall be proportionately reduced. Section 203 of the new Shipping bill amends the Revenue Act of 1921 to make more liberal allowance for actual depreciation of vessel property of all kinds.

Section 204 creates a new and ingenious method of indirect encouragement to the merchant marine by crediting shippers of exports and imports with 5 percent of the amount of freight money paid to American ships, as a deduction in computing Federal income taxes—but it is stipulated that this deduction "shall not be allowed with reference to transactions between persons who are affiliated"—that is to say,

* Vice-president and general manager, American Steamship Owners' Association, New York.

between corporations one of which owns more than 50 percent of the stock of the other.

Next comes, in section 206 of the new bill, the first provision for the raising of revenue to meet the expenditures. This is in the form of a doubling of the tonnage taxes and light money payable in our ports by all vessels, American and foreign, arriving in the foreign trade. Such an increase will produce a total revenue of about $4,000,000 a year, or double the present amount.

Transportation of Immigrants

A tremendously powerful new agency for the creation and maintenance of a first class naval reserve is embodied in section 301 of the Shipping bill, with its declaration that "as nearly as practicable one-half of the total number of immigrants admitted to the United States in any fiscal year shall be transported in vessels registered or enrolled and licensed under the laws of the United States."

In practical effect this would mean that one-half of the immigrants from the United Kingdom would come in American and one-half in British ships; of the immigrants from Germany one-half in American and one-half in German ships; of the immigrants from Italy one-half in American and one-half in Italian ships, and so on. This plan is so manifestly just and equitable that European shipping interests, which have a mortal fear and hate of the American bill, despair of finding any plausible pretext to defeat it. Their suggestion that commercial treaties forbid such a policy is upset by the well-known fact that before the world war those Europeans themselves had a working agreement by which the carrying of virtually all of our immigrants was regularly monopolized by foreign companies, a certain proportion to each company. Treaty prohibition was then undreamed of, but the bill arms the President with authority to "denounce" any section of any treaty as to which this point may now belatedly be raised.

Naval Reserve Fleet

Most valuable of all ships for National defence are the great, swift passenger carriers of the North Atlantic. Under this immigration section America is assured of as strong a naval reserve fleet as the United Kingdom, thus guaranteeing in logical effect the principle of the Washington 5-5-3 agreement of 1920, under which our naval power was to be equal to Great Britain's and about twice Japan's.

Subvention, subsidy, "compensation," as President Harding justly calls it, first appears in the Shipping bill in section 401 by which the merchant marine fund is established in the Treasury department. This fund is to be made up of the increased tonnage taxes, already alluded to, ($4,000,000 a year); 10 percent of the customs revenue (or about $30,000,000 a year); amounts that but for the general compensation would have to be paid under contract for carrying the ocean mails (except parcel post) (or about $4,000,000 a year), and in addition certain repayments to shipowners. From this fund amounting to from $36,000,000 to $40,000,000 a year, certain specific rates of compensation are to be paid under contract for 10 years to all American vessels engaged in overseas trade, calculated as to cargo vessels to meet the difference between American shipboard wages and subsistence and the wages and subsistence of their chief foreign competitors, and as to the swift mail, passenger and cargo vessels, to cover the difference in wages and subsistence, and also the subventions or subsidies of foreign governments.

Direct Compensation

The Shipping Board is charged with making these contracts only with capable and responsible persons or corporations. In amount this compensation begins with a rate of one-half of one cent per gross ton of a sailing vessel of at least 1,000 gross tons or of a steamer of at least 1,500 gross tons, for each 100 miles sailed in foreign commerce—steamers of from 1,500 to 5,000 gross tons are compensated as of 5,000 tons gross register. Power-driven vessels of a speed of 12 knots or over and less than 13 knots are to have an added compensation of one-tenth of one cent per gross ton for each 100 nautical miles sailed in foreign commerce—and so on by a carefully proportioned scale up to an additional two and one-tenth cents per gross ton for 100 nautical miles sailed by steamers of 23 knots and over. Mileage is to be measured by direct customary routes. On this basis, a 5,000-ton cargo steamer of 10 knots speed might receive a compensation of about $7,500 a year, while the 24-knot *Leviathan* of 54,000 tons might receive $900,000—a sum not out of proportion to what the British Government has long been paying the Cunard Company for similar service.

To emphasize the fact that all this compensation for either cargo craft or giant liners is for actual service rendered, certain conditions of National importance are established. In order to receive this compensation, ships must be already registered or hereafter built in the United States—with certain special exceptions. They must hold the highest classification of the American Bureau of Shipping—the "American Lloyds"; they must be self-propelled by sails or machinery, and must carry officers who are duly certificated American citizens, and crews exclusive of officers at least two-thirds of whom after two years are American citizens, the remainder to be persons eligible to citizenship. It is emphasized again that this compensation is given only to ships engaged in foreign commerce, and voyages in such commerce are strictly defined.

No compensation under the Act is to be paid to ships not of private ownership or not owned by citizens of the United States. After three years no company whose own or chartered tonnage, or the tonnage of whose affiliated companies, is not at least 75 percent of American register shall be eligible for compensation.

Wisely, some discretion is given to the Shipping Board to increase the rate of compensation by a record vote of five out of seven members, on routes where especially intense foreign competition makes this necessary—but the increase shall not be more than double. The Board is also authorized to reduce the rate of compensation where the rate seems excessive, with the consent of the other party to the contract.

Vessels receiving compensation may be requisitioned by the Government at any time for National defence or in a National emergency, on a basis of fair actual value, but in no case "shall such fair actual value be enhanced by the causes necessitating the taking." All repairs or reconditioning of compensated vessels must be made in the United States or its possessions (except such repairs as are necessary to the safety of the vessel) on penalty of withdrawn compensation.

Ocean Mail Service

Steamers receiving compensation must carry free of charge all ocean mails except parcel post. Owners whose vessels earn a net income of more than 10 percent must pay 50 percent of the excess to the United States, "but in no case shall the amount so to be paid exceed the amount of compensation earned in respect to such vessel." This requirement, of course, is intended as a vigorous check on profiteering.

All army or navy transport services are to be discontinued wherever the President finds that adequate facilities exist in private hands, and the government-owned transports are to be turned over to the Shipping Board or laid up, while the requisite services are to be performed by privately-owned American vessels under contract. All government officers must travel on American steamers whenever available, if

(*Continued on page* 642)

Standardizing Ocean Bills of Lading

By Robert E. Annin

It is safe to assert that a very large proportion of ocean shippers today have little realization of the conditions to which the acceptance of the ordinary form of bill of lading may bind them; and the substitution of one well-digested and carefully framed code for a mass of unknown verbiage of uncertain effect would in itself be a great protection to all shippers, even to those who did not know the provisions of the code itself. At least they would be guaranteed against certain lopsided absurdities which might practically deprive them of vital rights.

IN view of the vital character of the bill of lading as a receipt, an evidence of contract and a collateral document, it would, at first glance, seem surprising that there is not yet in general use a form so definite in its statement of ordinary responsibilities and exemptions, as to be satisfactory to the interests necessarily involved—that is to say the carrier, the underwriter and the holder for value (which includes the shipper or his assignees). For with the rapid growth of international trade, for over a century, there has been devoted to the problem a wealth of ability—commercial, financial, legal and judicial—which, it would seem, should have been sufficient to reach a result reasonably satisfactory to all parties concerned.

It is only when one considers the possible complications arising from sea-perils, the infinite variety of goods transported, diversity of voyages and the differences in jurisdictions which enter into international trade, that the obstacles to a just and comprehensive form of bill of lading can be appreciated.

In view of these factors, the best conceivable form could do no more than reduce the inherent risks of dispute and litigation, even if special forms could be devised, covering every kind of merchandise, on any possible voyage, under every possible combination of conditions, which is obviously impossible.

Since the bill of lading form usually originates with the carrier (who naturally protects himself to the utmost), the demand for reform has come either from the cargo owner (or his assignee) or from the underwriter, who assumes most of the liabilities for loss or damage which cannot be collected from the carrier.

And as a negotiable bill of lading is not only an evidence of contract for carriage, but the vital document in the set of commercial collateral, all provisions which leave in doubt the relative risks and liabilities of the parties in interest, must tend to impair its value and act as a potential cause of injustice to any holder.

Clear Definitions Important

Hence the interest of the underwriter in a clear definition of the carrier's responsibilities is obvious; for only so may he intelligently estimate his own risk.

To the banker it is essential that, if his security be impaired by loss or damage, he shall have well-defined recourse against either the ship or the insurance. Otherwise he may risk falling between two stools, with no remedy, save in a dilatory and expensive litigation.

A curious case which occurred some years ago will illustrate this point. A shipment of cotton sheetings, in transit by a passenger and freight liner, was seriously damaged by the leakage of a bathroom pipe. The underwriters referred claimants to the carrier, holding that "sea peril" did not cover the kind of damage sustained. On the other hand the carrier rejected the claim, on the ground that the leakage was caused by straining of the ship, and consequently the damage was due to "sea peril." Whether the plumbing was originally defective, or the break caused by stress of weather on the voyage, seemed impossible of proof. The dispute dragged along for some months, when the underwriters, under pressure, accepted the liability and paid the claim in consideration of cargo owner's assignment of their claim against the carrier. Eventually, an amicable settlement was made by which carrier and underwriters each bore one half of the total loss.

In this particular case the shipper was a large insurer, with an enviable record as to claims, while the claim was not large. Furthermore, the essence of the matter lay in a question of fact, rather than of interpretation. But it is a clear example of the possible loss involved to an innocent holder of the bill of lading, whenever the line is not clearly drawn between the liability of the carrier and that of the insurer.

Unjust Exemption Clauses

Hence the demand for legislation which shall restrain carriers from inserting in their forms, unjust, obscure or tricky clauses, exempting them from their just responsibilities and transferring to other parties in interest the risks for which the ship is properly liable.

The conditions of international trade during the years just passed have brought this matter to an acute stage. For the collapse of markets, credits and exchanges has loaded bankers with "frozen credits." Drawees have failed to meet their drafts; drawers have been unable to take them up and the holder's sole tangible security has been the value of goods. When to this is added the fall in price and the anxiety of both owners and underwriters to plead any technicality to escape payment of claims the urgent demand for bill of lading reform is easily understood.

The trouble, at this juncture, has been further intensified by unusual and unjust exemption clauses inserted in their form by some carriers, under the plea of "war conditions"; and which in many cases have survived the emergencies which served as their excuse.

While the war lasted, and for a year thereafter, the insufficiency of tonnage was so great that shippers were willing to accept almost any bill of lading so long as their goods were moved.

A glaring instance of this kind is the following clause inserted in a "war" bill of lading and accepted without demur by many shippers:

"For the purpose of ascertaining the amount of freight to be charged, the shippers shall make a written declaration, before shipment, of the true contents and value of each package; and any failure to make such declaration, *or the making of any incorrect or insufficient declaration, shall release the carriers from all responsibility and shall entitle them to charge double freight,* calculated according to the true contents and/or value of the goods."

The effect of such a clause upon the value of the bill of lading as collateral needs no comment. That it would receive judicial sanction is doubtful, but that it would cause litigation is very certain; a fact which of itself greatly impairs the value of any collateral document.

Stipulations Not Necessarily Final

While a bill of lading as a contract is not assailable by parole evidence and while the courts are disinclined, for obvious reasons, to nullify its express stipulations, it cannot be assumed that its provisions are necessarily final in all cases. A long standing decision on this point holds the following language:

"A bill of lading is not the contract, but only evidence of the contract; and it does not follow that a person who accepts the bill of lading which the shipowner hands him is necessarily and without regard to circumstances bound to abide by all its stipulations."

The same decision held that in case of novel or unusual clauses, vitally affecting the ship's liability, the shipowner is obligated not only to make it plain in words, but conspicuous in type and position.

Further, courts have long shown an increasing tendency to interpret the bill of lading along lines which reasonably recognize its vital importance in international commerce, and the special risks to which bankers and underwriters may be subjected without a fair chance to protect their interests. A clear division of liabilities and risks incident to ocean transportation is one of the roots of a safe international commerce.

For such reasons the call for standardization has become increasingly clamorous and has taken form in two directions:

(a) By a movement acting through the British Board of Trade for legislation on the subject to cover all British territory.

(b) By the formulation of a code of international regulation which has become widely known as the "Hague Rules."

The former may be framed either on identical lines with the Hague Rules, or (as has been proposed) upon the model of the existing Canadian Act; in which case its effect would be restricted to the British Empire itself. The latter would require the assent of the interested Governments to become generally effective. There is a strong movement to accomplish the adoption of the Hague Rules through action of our own Congress. It is true that much of the ground which it is sought to cover has been already covered in the Act of Congress of 1893, known as the Harter Act. But the latter is 30 years old, has shown some hazy spots and could undoubtedly be improved in the light of so many years of experience and judicial review.

No Code Can Completely Cover Every Trade

As before stated, no code could be attempted which should provide a complete form for every trade, every jurisdiction and every class of cargo. The aim is rather to frame a set of rules which shall be clearly expressed, easily grasped and which being briefly made a part of all bills of lading (by the same method now used to give effect to the Harter Act and the York-Antwerp Rules) would not only accomplish the purpose desired, but by such method would automatically shorten and simplify the bill of lading form. This is in itself an end worth achieving, for the interminable length of many forms now in use is an injustice to shipper, banker and underwriter, only less than that caused by unconscionable provisions.

The Hague Rules were originally drafted by the Maritime Law Committee of the International Law Association, in the endeavor to lessen and, if possible, remove the universal friction between carriers and holders of bills of lading which has been growing for years; but which became particularly acute about the end of the war period. Previous to this, the Prime Ministers of Great Britain and her Dominions had moved in the same direction and British legislation was already in prospect which should cover all that Empire, but would of course be ineffective beyond its boundaries. The purpose of the International Law Association has been to broaden the movement, so that, by the formulation of a code acceptable to all the martime nations, the reform might be made of world scope.

International Code Framed at The Hague

At a general conference of the International Law Association, which met at The Hague in August last, the rules drafted by their Maritime Law Committee were submitted, exhaustively discussed and (after certain amendments) this code, known from the town of its adoption as the Hague Rules, was adopted unanimously.

The ability and time given to the framing of these regulations have given them such prestige, and wide discussion of their provisions has so justified their wisdom and fairness, that there is good hope that many of the maritime nations, headed by Great Britain, may adopt the essence of the Hague Rules as a part of their maritime law. The International Chamber of Commerce is taking an active interest in promoting the movement and a majority of those interested in this country are in hearty accord with their purposes.

It will not be practicable in the space available to quote the rules in full and comment thereon; but a brief summary of the provisions of the various sections with some comments on the more vital should be of interest.

Articles I and II

In the Hague Rules as written Articles I and II are formal, the first defining the essential terms "Carrier," "Contract of Carriage," "Goods," "Ship" and "Carriage of Goods." The second makes the rules binding upon the carrier.

Article III

Article III is devoted to the carrier's responsibilities and liabilities. Section one of this article states the ends toward the accomplishment of which the carrier is obligated to exercise due diligence "before and at the beginning of the voyage."

Section two provides for loading and discharging and care of cargo while in carrier's custody.

Section three treats of the issuance of bill of lading, on demand of shipper as soon as goods are in carrier's custody; and of the descriptive details which such document shall show.

Section four provides that (with the exception of bulk goods) the bill of lading shall be prima facie evidence as to marks, quantity, description and condition, at time of shipment.

Section five is, on its face, for the special protection of the carrier, but in effect it is for protection of the shipper against just such clauses as the one quoted some time back. It provides that the shipper shall indemnify the carrier for any loss, damage or expense resulting from inaccurate descriptions.

Section six treats of claim for loss or damage; of the giving of notice by claimant, and discharges the carrier in respect of loss or damage, unless suit is brought within twelve months after delivery of goods.

Section seven provides that shipper shall be entitled, when goods have been loaded, to demand a bill of lading stating that goods have been "shipped" instead of "received for shipment"—a point upon which later comment is to be made.

Article IV

Article IV treats of the rights and immunities of ship or carrier.

Section one has broadly the effect of the Jason Decision under the Harter Act in exempting the owner for unseaworthiness not caused by lack of due diligence on the part of the carrier.

Section two is in effect the provision setting forth the exemptions to which the carrier and/or the ship are justly entitled. It is notable for its relative brevity and clarity, being content with the more general descriptions of causes of loss for which the carrier shall not be responsible, instead of attempting an impossible completeness of detail. For such detail is substituted one last paragraph (q) which specifies among the exemptions

"Any other cause arising without the actual fault or privity of the carrier; or without the fault or neglect of the agents, servants or employees of the carrier."

Section three contains the deviation clause.

Section four limits carrier's liability to £100 per package, unless a higher value be declared by the shipper, before shipment, and inserted in the bill of lading. Herein is covered one of the points which have caused complaint, friction and conflict.

Section five exempts carrier or ship from responsibility for all loss or damage in connection with goods the nature or value of which has been *wilfully* misstated by the shipper.

Section six grants to the carrier full freedom of protective action in regard to dangerous cargo, the nature of which has been concealed by the shipper; deprives shipper of any claim for compensation and makes him liable for all loss or damage due to his failure to declare the true nature of the cargo.

Article V

Article V provides for goods carried under special agreements not in accord with the preceding rules. Such contracts are to be legal but no negotiable bill of lading is to be issued under them. In lieu thereof, the agreed terms are to be embodied in a receipt, marked *"not negotiable."* The effect of this rule, in preventing the misleading of holders for value through special agreements between shipper and carrier, as well as placing the sole onus of such agreements upon the parties directly assenting to them, is very clear.

The code as proposed is mainly drawn along the lines of the Harter Act, and like that law, it is primarily intended for the protection of other interested parties against arbitrary and unjust provisions dictated by the carrier or ship.

In the provisions for due diligence it is plainly implied that the burden of proof that such due diligence has been exercised shall rest upon the carrier. The cargo owner does not have to prove negligence. This might be made clearer by direct expression, but the intent appears unmistakable. In brief the Hague Rules aim (as does the Harter Act)

(1) To prohibit the evasion of certain vital obligations by the carrier.

(2) To clearly and tersely define the just exemptions of the carrier.

The ultimate purpose is to make the application of such prohibitions and definitions general, instead of (in the international sense) local.

But this code also covers certain matters long in controversy upon which the Harter Act does not touch.

Specifically in Article III, Section 6, it is stipulated that in the absence of written notice of claim served upon the carrier at port of discharge before removal of the goods, such removal shall be prima-facie evidence of delivery. Further that failure to bring suit within 12 months of delivery shall discharge the carrier from all liability in respect of loss or damage. This is in sharp contrast with clauses commonly in use which, in some cases, have exempted the carrier absolutely unless written notice of claim be served within ten days of removal; and limiting to three months the period within which suit may be brought. Clearly, in view of the possibilities of delay in the detection of damage (arising from transshipment, warehousing, and other causes), the period for the absolute exemption of carrier has often been too short. The acceptance of the goods being made *prima facie* evidence of delivery places the burden of proof of damage upon the cargo, but does not absolutely release carrier.

In view of the time and labor required in seeking and formulating evidence, the difficulty of locating witnesses, etc., the period of one year allowed for the beginning of litigation appears reasonable.

Much trouble and confusion has resulted from the issuance by carrier of bills of lading which failed to name definitely the vessel upon which cargo had been shipped. Presumably this practice arose with the use of "Through Bills of Lading" where (owing to uncertainties of transport to seaboard) it was impossible to guarantee that a given consignment would arrive in time for shipment by a given ship. Carriers were quick to perceive the advantage to themselves of a form which, instead of binding them to the statement that the goods were *"Shipped per"* a given vessel, merely stated that goods had been *"Received for shipment per———"* or succeeding vessel of the same line. Under the latter form the privilege to the carrier of selecting the most profitable cargo for immediate shipment, and of shutting out less desirable consignments led to infinite confusion, trouble and loss. Not only were split shipments common, but shipper, consignee, banker and underwriter were often uncertain regarding the identity of the vessel to which their risks attached. This form was therefore a convenience to the ship but an injustice to all other interests.

Hence in Article III, Section 7, it is provided that when goods are actually aboard, the shipper shall be entitled to demand, and the carrier must issue, a *"Shipped"* bill of lading, provided no *"Received for shipment"* bill of lading has previously been issued.

But, if the latter has been already issued, it shall (on goods being laden and on demand of shipper) be exchangeable for a "Shipped" bill of lading; or a "Received for Shipment" form may acquire the standing of a "Shipped" form, by proper notation of name of ship and date of lading, by the carrier, master or agent.

This does not altogether avoid the complications of a "Received for Shipment" form, but certainly greatly modifies them.

Cargo of Unusual Value

The reform of another abuse is covered in Article IV, Section 4. That the carrier may have some knowledge of the risks which he undertakes it is essential that he be informed concerning cargo of unusual value. In regard to precious stones or metals, securities, laces, furs, and certain other valuable commodities, which are subject to special perils of theft or damage, the ordinary bill of lading requires a special declaration of the shipper at the time the engagement is made. This is clearly just, since the carrier's risk as to loss and damage is in proportion to the value of the goods carried and he is entitled to be warned in advance regarding any items which are subject to peculiar risks, in order that proper protection may surround them.

But also to cover this matter in a more general way there has been a customary clause placing a maximum risk *per package* on all goods the value of which has not been declared in advance by the shipper.

As it is to the interest of the carrier that this maximum should be as low as possible the tendency has been to reduce it below a reasonable figure to the great disadvantage of the shipper in case of loss. Article IV, Section 4, places this general maximum at £100 per package also providing that, by special agreement any other maximum, *not less than* £100-0-0, may be substituted.

This section also very properly stipulates that shipper's declaration shall only be *prima facie* evidence as to value, etc., but shall not be binding upon the carrier. Otherwise it might be claimed that acceptance of declaration of value would estop the carrier from later disputing its accuracy, thus opening the door to a very obvious kind of fraud.

These are the main features of the so-called Hague Rules which, to be made fully effective must be made part of the statute law of the great maritime nations.

As this is written the subject is under active discussion in the United Kingdom and many suggestions of amendment and alteration have been made. The tendency of most of these, however, seems to be toward greater simplicity and definiteness and indicates that the British interests involved are in dead earnest in their endeavor to better present conditions. Presumably this process will have to be gone through with each national parliament and the consequent delay is quite likely to endanger the general success of the Hague Code. In the interest of international trade it is to be hoped that this movement will succeed. The unification of law and practice in respect of these matters would simplify and therefore facilitiate international commerce. Whatever does this is in the long run beneficial to both owner and operator; while the interests of bankers and underwriters are too obvious to need comment.

Hence the speedy success of these rules is greatly to be desired in the interest of ocean trade.

Recent Developments in Marine Insurance

Deviations for Fuel—Pilferage Liability—War Clause Altered—Proposed State Law—Shipping Destroyed in 1921

By "Bordereaux"

COAL shortage continues to be the cause of considerable anxiety to marine underwriters, for more reasons than one. They are checking up on voyages with the greatest care, watching particularly for deviations for fuel. Recently several English vessels that loaded at New York for the River Plate proceeded to Sydney, Cape Breton Island, for coal, not having been able to fill their bunkers here. They found at Sydney that they could not secure a sufficient supply and were obliged to go to Norfolk to get it. All this involved extensive and perilous deviations and the underwriters, very properly, charged an additional premium of from one-eighth to twenty cents. Many serious hazards are caused by these entries into other ports than those contemplated in the prescribed voyage. Collisions are always possible and the peril of fire damage is never absent when hatches are opened for the reception of coal.

Would Sue the Government

PERMISSION to bring suit against the Federal Government is something the marine underwriters are very desirous of securing. Behind it lies the important question of the liability of the Government for war damage. The insurance men want to see the Husted bill, now pending before the Congress, reported out of committee; if this measure can not be passed, they want a new bill introduced. The Husted bill seeks to secure permission to bring suit against the Government. A few days ago a special meeting of marine insurers was held at New York for the purpose of inaugurating an inquiry of nation-wide scope into the liability of the United States Government for war damages. It is desired to have this action taken up all over the country, as in such an event it would present vastly more strength than if pushed by any local interests. William H. McGee presided, and the meeting authorized him to appoint a committee that should study the situation and devise ways and means for meeting it. After mature consideration Mr. McGee made the following appointments to the committee, of which he himself will act as chairman: Curtis L. Clay, Philadelphia, representing the Insurance Company of North America; W. H. Jones, of S. D. McComb & Company; H. E. Reed, of the Fireman's Fund; H. A. Warden, of the Automobile; and G. B. Ogden, of Chubb & Son.

Havana Trouble Feared

THERE appears to be good reason for fearing the development of another period of congestion at Havana approximating in extent the chaotic conditions that prevailed there a few months ago. The Cuban Government has discharged more than one-half of the Post Office employees, and these were experienced hands who knew how to handle the routine of the Department. Singularly enough, those who were retained are novices who have it all to learn. The result has been confusion. Many stacks of mail are waiting to be distributed, and there is no doubt but that in those heaped-up pouches are reposing numerous documents for merchants who are expecting shipments by incoming steamers. Should these clearance papers fail to be delivered by the Postal authorities to the merchants, the cargo, when discharged, must unavoidably accumulate on the docks until the necessary customs documents are received.

Foreign Pilferage Liability

SHIPOWNERS and operators will find much to interest them in the query and answer herewith referred to respecting the problem of how far the specific stipulations in a bill of lading (trans-oceanic shipment) may be regarded as null and void, if at all, owing to their infringement of the provisions of the Harter Act. Trade Commissioner Julian E. Gillespie recently submitted to the Division of Commercial Laws a case of disputed liability for pilferage which occurred in the port of Constantinople. The Division referred the matter for opinion to a firm of well-known admiralty lawyers of New York, the substance of whose reply is as follows:

It has been repeatedly held by our courts that the Harter Act applies to foreign vessels which come within the jurisdiction of American courts as well as to American vessels, provided the loss or damage complained of occurred on a voyage to or from a United States port. If the consignee takes delivery of his goods, any damage arising thereafter cannot be imputed to the ocean carrier. Although the question of liability for damage upon lighters at destination is constantly recurring, the effect of the Harter Act thereon, curiously enough, has never been passed upon by our courts. There are decisions holding where cargo is laden upon unseaworthy lighters hired by a steamship company and used to carry cargo to the vessel that the voyage first commenced when the cargo was laden on board the lighter, and the unseaworthiness of the lighters renders not only the owners of the vessel liable for the loss ensuing but also renders the vessel liable *in rem*.

Upon the same principle the legal advisers express the opinion that, if upon a vessel's arrival at destination cargo is laden upon lighters employed by the carrier for transportation to the shore, the steamship company is liable for a loss that arises either through the unseaworthiness of the lighter or through improper custody and care of cargo on the lighter, inasmuch as, in their judgment, the lighter is a substitute for the vessel to complete its contract of carriage. Bills of lading, it is true, almost invariably contain a provision that the steamship company or the vessel shall not be liable for loss arising after transshipment, "but we are of opinion," said the attorneys, "that the transportation of goods upon lighters does not come within the meaning of such a clause, as lighters are not really independent carriers but are merely auxiliary to the real voyage."

They also feel that inasmuch as a voyage has been declared by the courts to start when goods are laden upon a lighter provided by the carrier to carry the goods to the vessel (Bulkley *v.* Naumkeag Steam Cotton Company, 24 Howard 286), it would seem to follow logically that the voyage does not terminate until the goods are discharged upon the dock, at the termination of the voyage, where the carrier furnishes the lighter. Whether it be considered that the goods are still in transit or are in course of being discharged from the vessel, these attorneys maintain that the provisions of the bill of lading in reference to the liability of the steamship company for loss or damage to the goods while on the lighter are governed and limited by the provisions of the Harter Act.

Sections 1 and 2 of the Harter Act provide that a carrier cannot lawfully exempt himself by a provision in the bill

of lading from liability for loss arising from negligence or fault or failure in the proper custody, care or proper delivery of any lawful merchandise committed to his charge and that any such provision in a bill of lading shall be null and void and of no effect. It is the opinion of these attorneys that it should properly be held that the goods are still "committed to his (carrier's) charge" and are being "delivered" by him while the goods are on the lighter.

The final conclusion of this interesting opinion is as follows: "The inclusion in the bill of lading of a clause that the carrier shall have liberty to convey the goods upon lighters at the risk of owners is a provision rendered null and void by the provisions of the Harter Act (Section 1), and if loss or damage arises to the cargo on the lighters through unseaworthiness or through negligent care and custody of the cargo, the steamship company may be held liable therefor in a suit *in personam* and probably the vessel also held liable *in rem*."

Influence of the Greco-Turkish War

Underwriters are becoming increasingly wary about covering shipments to and from Asia Minor in view of the possible influences of the war between Greece and Turkey. Goods destined to either one of the belligerent countries are exposed to increased war hazards. Recently an important decision was handed down regarding liability for seizures of the property of the assured by de facto governments, and a considerable number of underwriters are now employing an altered war clause to conform to this requirement. De facto governments are not regarded as governments within the meaning of the clause. The new form is as follows, the italicized portions being the recent additions:

"Including direct loss and/or damage caused by strikers, locked-out workmen or persons taking part in labor disturbances, riots, civil commotions or explosions, the result of unlawful acts, but, notwithstanding anything to the contrary, either expressed or implied herein, or in the policy to which this endorsement is attached, this insurance does not cover and is hereby warranted to exclude claims for delay, deterioration or loss of market, or for confiscation or destruction by the Government, *and/or de facto Government*, of or within the country in which the property is situate and/or the Government, *and/or de facto Government of seceding or revolting States.*

Proposed State Law

At the meeting of the National Convention of Insurance Commissioners, held at Swampscott, Mass., on September 5-7, representatives of the American Institute of Marine Underwriters submitted a draft of the proposed uniform State marine insurance law as prepared by counsel to that body. It is largely based upon the new Marine Law of the District of Columbia, with certain alterations that should render it more acceptable to insurance men at large. The purpose is to have legislation of this character approved and advocated by the supervising authorities of the States, to the end that the conflicting requirements of the States may be smoothed out and American marine underwriters be afforded a uniform and scientific basis upon which to build up a business in keeping with the requirements of our new merchant marine. It is now up to the Committee on Laws and Legislation of the Insurance Commissioners. Of this important and essential legislative suggestion it may be said:

1. It has not been drafted in the interest of any particular State or group of States but as a practical and necessary aid to the development and advancement of the interstate and foreign commerce of the United States and the better to enable American shipowners, merchants and marine underwriters to meet world competition.

2. It has not been drafted in the interest of corporate insurers as distinguished from mutuals, inter-insurers or individual underwriters; its aim is to be fair to all and to provide equal opportunity for all.

3. The proposed State act does not intend to, nor does it, alter or restrict the complete control of the supervision, regulation or taxation of marine insurance by the States or by State officials.

It leaves untouched, or rather, it perpetuates, the supervisory powers of State commissioners of insurance. Its sole endeavor is to obtain substantial State uniformity of regulation and taxation in respect to a business which is of national concern and unique in character.

4. Its purpose is "to define, regulate and tax marine insurance," not to prepare an insurance code covering matters of substantive law as in the code States.

Shipping Destroyed in 1921

A report upon disasters to vessels during 1921 has been issued by *Lloyds Register*. It includes those that were lost at sea, broken up, condemned or otherwise removed from trade, and the grand total is 559 ships with a tonnage of 674,257. Of these, 344 were steamers and motor vessels, with an aggregate of 536,537 tons, and the balance sailing ships. Strandings and kindred casualties which are comprised under the term "wrecked" are the most prolific cause of disaster. To such casualties are attributable 45.16 percent of the losses of steamers and motor vessels and 38.8 percent sailing vessels. Cases of abandoned, foundered and missing vessels are, no doubt, frequently more or less similar in the circumstances of loss. If these be taken collectively, they form 30 percent of the steamers and motor vessels and 35½ percent of the sailing vessels removed from the mercantile marine during 1921, owing to casualty.

Of the 310 steamers and motor vessels totally lost, condemned, etc., during the year, 65 of 65,718 tons gross (0.34 percent of tonnage owned) were registered in the United Kingdom; 35 vessels of 42,332 tons (1.87 percent) in the British Dominions; 22 of 60,392 tons (0.45 percent) United States; 8 of 5,536 tons (0.63 percent) Denmark; 21 of 27,899 tons (0.85 percent) France; 12 of 7,005 tons (1.07 percent) Germany; 26 of 52,363 tons (8.92 percent) Greece; 2 of 602 tons (1.14 percent) Italy; 29 of 51,185 tons (1.53 percent) Japan; 16 of 28,210 tons (1.23 percent) Norway; 30 of 53,772 tons (4.84 percent) Spain; 8 of 9,693 tons (0.89 percent) Sweden; and the balance of 21 vessels owned in other countries.

As regards material of construction, 186 vessels of 360,449 tons were of steel; 45 of 46,206 tons of iron; 5 of 2,508 tons of ferro concrete; and 75 of 49,829 tons of wood and composite. Of the sailing ships totally lost, etc., out of the total of 193 vessels of 121,834 tons, 50 vessels of 46,753 tons were owned in the United States. The amount of tonnage broken up, dismantled, etc. (not in consequence of casualty) in 1921 was 93,431 tons.

International Oil Pollution Parley

Marine insurance men are naturally greatly interested in the official announcement from Washington to the effect that President Harding has authorized Secretary of State Hughes to enter into negotiations with the principal maritime nations of the world for a conference in the United States for a discussion of means of preventing oil pollution of navigable waters, especially in important harbors. No date for the parley has been intimated as yet. This action carries out a resolution adopted by Congress requesting the President to call such a conference. The State Department proposes at once to start an inter-depart-

mental inquiry along broad lines with the purpose of working out possible ways and means of solving this grave problem so far as this country is concerned. Every department of the Government using ships, the Shipping Board, Public Health Service, Biological Survey and the Bureau of Mines will participate in the inquiry. The problem involves finding a practical way to overcome the pumping out by tank steamers or oil fuel vessels of ballast water when nearing port, the ballast water having come from tanks which previously contained fuel oil and carrying with it into the sea a scum of heavy oil.

Japan Hull Risks

LONDON, during recent years, has been receiving a considerable amount of hull business from Japan, in the form of reinsurance of Japanese companies. Hitherto this business has gone exceedingly well but of late there have been complaints that the risks which are being sent are not of the best, while the rates paid are far from being satisfactory. The reinsurances are, for the most part, effected under a twelve-monthly contract and, although it is now too late to undo any harm that has been done, underwriters are keeping the matter under close observation for future regulation of their action.

Shipping Board to Conserve Coal

A FUEL Conservation Section, with headquarters at 45 Broadway, New York, has been established by the United States Shipping Board Emergency Fleet Corporation, according to Operations Order No. 16, issued by Joseph E. Sheedy, vice-president of the Emergency Fleet Corporation.

This Section is the active arm of the Fuel Conservation Committee and the specific duties entrusted to it are to make practical and technical studies of the methods of operation of vessels as regards their motive power and to suggest and promulgate means to improve these methods and consequently reduce the fuel bill of the Fleet Corporation.

This Section may require assistance of various kinds from time to time from other Departments in order to further its work. All Department officials and employees of the Corporation are requested to co-operate to the fullest extent in bringing about the desired results.

C. J. Jefferson is designated as Head of this Section and will be in active charge of its work.

The Fuel and Operating Departments of the Corporation will continue to function as heretofore in connection with the purchase, receipt and use of fuel.

Whaler Leaving New Bedford, Mass., for an Atlantic Voyage

The sailing of a whaling vessel from New Bedford Harbor, which years ago used to be a common sight, is now an unusual event. The above illustration shows the recent departure of the whaling bark Wanderer from this port for Cape Verde Islands to recruit a crew for an Atlantic whaling voyage, under command of Captain Joseph Edwards

The New 17,200-Ton Anchor Liner Tuscania

Latest Type of Present-Day Passenger Liner Practice Arrives in New York—Replaces Namesake Lost During War

ALTHOUGH there has been a large amount of passenger liner tonnage completed in English shipyards since the armistice was signed it is worthy of note that not one mammoth liner has been projected or designed. All of that type which have been put in service are simply completions of pre-war projects.

The Cunard Company has been the leader in the post-war practice of building vessels of the intermediate type of between 13,000 and 20,000 tons. These vessels, however, contain many of the comforts and conveniences that were formerly only to be found in the monster greyhounds. In other words, they are comfortable without being too luxurious and therefore adapted to the needs of the average pocketbook rather than that of the millionaire.

One of the latest vessels of this class to be completed is the *Tuscania,* which arrived in New York on September 27. The *Tuscania* was built for the Anchor Line (Henderson Bros.) service between Mediterranean ports and the United States and is fitted out in accordance with the emigrant regulations of Great Britain, Italy and the United States.

The Anchor Line practice of perpetuating the names of its vessels has been carried out in this case and the new vessel is named after an earlier *Tuscania* which was built in 1915 and lost during the war. The new vessel is slightly larger than her namesake and having more erections is also both wider and deeper, the gross tonnage being thereby increased from 14,348 to 17,200.

Main Particulars

The *Tuscania* is a twin screw passenger and cargo steamer and will be propelled at a speed of 17 knots by Brown-Curtis double reduction geared turbines of 13,500 shaft horsepower. She is of the same dimensions and generally similar to the recently completed *Cameronia* but has an additional deck amidships and consequently more space available for the accommodation of passengers.

The leading particulars are:

Length over all	578 feet 6 inches
Length between perpendiculars	550 feet
Breadth molded	70 feet
Depth to bridge deck	51 feet 3 inches
Load draft	28 feet 11¾ inches
Deadweight	about 10,700 tons

The vessel has been constructed under special survey to the Rules of the British Corporation, and is fully in accordance with the recommendations of the International Convention for the Safety of Life at Sea, a standard largely in excess of the present legal requirements as to sub-division. She is of the shelter deck type and has a straight stem and cruiser stern, and will be fore and aft rigged with two masts and one funnel. There are in all eight decks, viz.: lower, main, upper, shelter, bridge, lower promenade, upper promenade and boat deck.

Construction of Hull

The vessel is subdivided into eleven main transverse watertight compartments by ten watertight bulkheads, the fore peak bulkhead is carried up to the bridge deck while the others extend to the shelter deck. All watertight doors below the waterline are worked on the Stone-Lloyd system, also by gearing from the shelter deck. Fire resisting bulkheads with fireproof doors are fitted in the accommodation spaces above the shelter deck.

A double bottom is fitted all fore and aft between the peak bulkheads, and is utilized for carrying oil fuel, reserve feed water and water ballast. The fore peak tank is used for either fresh or salt water and the aft peak for water ballast.

Passenger Accommodations

The passenger accommodation is all situated above the main deck, the spaces beneath that deck being devoted to the carriage of cargo, ship's stores, machinery and bunkers. Three classes of passengers are carried and the accommodation is so arranged that a number of the rooms are interchangeable to either first or second class, the third class being berthed in open berths on the main and upper decks. The following are the numbers of passengers and crew for whom accommodation is provided:

First class	104
First interchangeable to second class	163
Second class	377
Third class (open berths)	1,818
Officers and crew	342
Total persons on board	2,804

The first class accommodation is all arranged on the lower promenade deck and consists of rooms for one, two and three passengers. The first and second class interchangeable rooms are mostly on the bridge deck, with a few on the shelter deck. These rooms accommodate from one to four passengers. The staterooms throughout are fitted with beds, settees, washbasins, dressing tables, wardrobes, and are complete with all furnishings necessary for the comfort of the passenger.

First Class Public Rooms

The first class public rooms, comprising dining saloon, lounge, writing room, smoking room, gymnasium and verandah cafe, are all large and airy apartments tastefully decorated and furnished. Their sizes are:

Dining saloon	52 feet by 68 feet by 8 feet 6 inches
Lounge	24 feet by 38 feet by 12 feet
Writing room	14 feet by 34 feet by 8 feet 6 inches
Smoking room	36 feet by 38 feet by 8 feet 6 inches
Gymnasium	14 feet by 29 feet by 12 feet
Verandah cafe	14 feet by 38 feet by 8 feet 6 inches

The dining saloon is situated on the upper deck and is entered direct by the main staircase. It occupies the full breadth of the ship and is surmounted by a large dome and musicians' gallery. Dining accommodation is provided for 158 passengers arranged at small tables accommodating from four to twelve persons, the floor area being about 20 square feet per person accommodated.

The remainder of the public rooms are in the deck house on the upper promenade deck. The lounge is at the forward end of the house just forward of the main stairway, the writing room alongside the funnel hatch, the smoking room between the funnel and engine hatches, the gymnasium aft of the engine hatch and the verandah cafe at the aft end of the deck house.

Second Class Accommodations

The second class public rooms include a dining saloon, lounge and smoking room. The dining saloon, 64 feet by 68 feet, is on the upper deck and has dining accommodation for 256 people. This can be increased to 272 by extending some of the tables, the floor area being then 18 square feet per person. The tables are arranged to accommodate from

two to fourteen people. The lounge and smoking room is situated in a deck house on the lower promenade deck with the main second class stairway between them. These rooms are furnished with comfortable chairs, sofas and settees. A piano is placed in the lounge and a bar arranged in the smoking room.

Third Class Accommodations

The third class passengers are berthed in open berths on the upper and main decks. Dining spaces are arranged on the main deck amidships and on the shelter deck forward. Smoking rooms and sitting rooms are provided on the upper and shelter decks aft.

Ample open and covered promenading spaces have been allotted to each class of passengers.

Careful attention has been given to the accommodation for the officers and crew of the vessel. The captain's rooms are on the bridge, officers on the lower promenade deck, engineers, petty officers and seamen on the shelter deck, firemen and stewards on the upper and main decks. Separate mess and recreation rooms have been provided for seamen, firemen and stewards.

The culinary department for the passengers and crew are replete with all the necessary equipment and fittings. The passengers' galley is placed on the upper deck between the first and second class dining saloons and the crew's galley is forward on the shelter deck.

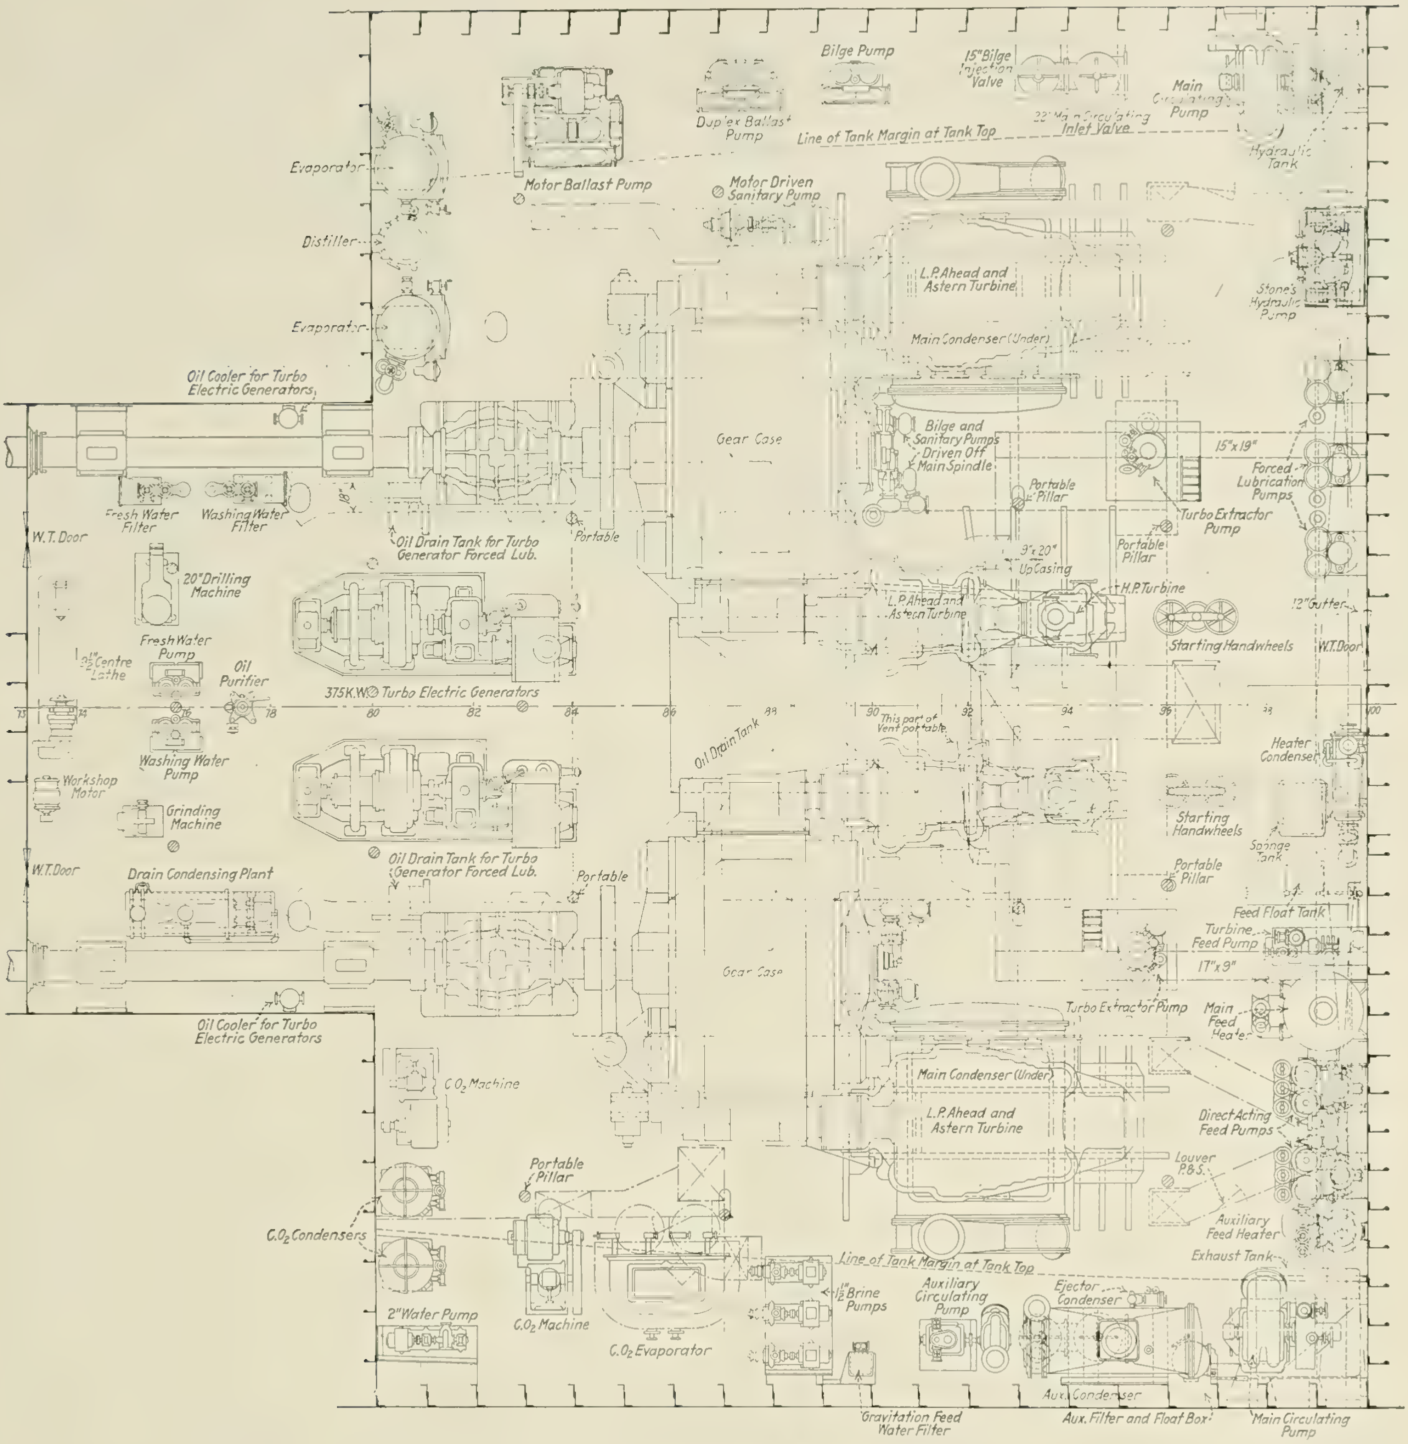
The lifesaving equipment is sufficient to meet the requirements of all on board and is in accordance with the provisions of the International Convention on Safety of Life at Sea. The boats are placed under fourteen sets of davits of the "Welin" type.

Heating and Ventilation

The sanitary arrangements are of the most modern description and four distinct water services are provided. The first and second class accommodation, officers and petty officers rooms are heated by steam radiators while the third class and crew's quarters are heated and ventilated by the thermotank system.

Deck Machinery

As the vessel has a large cargo carrying capacity special attention has been paid to the appliances for rapidly handling



Plan of Engine Room, S. S. Tuscania

the cargo. Fourteen derricks are fitted each capable of supporting five tons; these are operated by means of electro-hydraulic winches.

All the deck machinery, including the windlass, is electrically operated. The steering gear, which is placed on the lower deck, is of the Hele-Shaw type, operated by telemotor gear from the navigating bridge.

Electrical Plant

A complete electrical installation is fitted throughout the ship. The generators consist of three sets of engines coupled to three dynamos, each of which is capable of giving an output of 100 kilowatts at 110 volts. In addition to these an emergency dynamo and engine is fitted in a deckhouse on the bridge deck.

A patent fire extinguishing system is fitted throughout the ship.

Insulated and other stores are placed aft on the lower deck. The refrigerating machinery for the insulated stores is of the CO_2 type and is placed in the engine room.

A wireless installation is installed to meet the requirements of the Italian Laws.

The deck covering throughout all accommodation is of Teakoid and in all lavatories and galleys Terrazzo tiling. Weather decks, where exposed, are laid with pitch pine.

Propelling Machinery

The propelling machinery consists of two sets of Brown-Curtis turbines, driving twin screws through double reduction gearing. Each set comprises three turbines, a high pressure and an intermediate pressure turbine being coupled together in tandem driving one first reduction pinion of the gearing, and a low pressure turbine driving the other first reduction pinion. A high pressure astern turbine is incor-

porated in the same casing as the intermediate pressure ahead turbine, and a low pressure astern turbine is incorporated in the same casing as the low pressure ahead turbine.

Boilers

Steam is generated in 3 double ended and 3 single ended boilers of the cylindrical return tube type, installed in one boiler compartment and designed for a working pressure of 220 pounds per square inch, superheaters being fitted capable of superheating the steam 200 degrees at the turbines. There is a complete installation, in duplicate, for burning oil fuel on the Howden-Wallsend system and provision is made for readily converting the boilers to coal burning if so desired at a later date.

Auxiliaries

In place of the usual air pumps, etc., for maintaining the vacuum and dealing with the feed water, Weir's patent "closed feed" system will be fitted, rotary water extractor pumps and air ejectors taking the place of the air pumps.

A special condensing plant is fitted in connection with the ship's heating system to ensure a perfect control of the temperature in the accommodations, while the more important of the auxiliary engines in the engine room, such as sanitary and ballast pumps, are fitted in duplicate, one of each being arranged for steam and one for electric power drive.

S. S. Steelore Launched at Sparrows Point Shipyard

The S. S. *Steelore,* a 20,500-ton turbine driven freight vessel, was launched at the Sparrows Point Plant of the Bethlehem Shipbuilding Corporation, Ltd., on August 15. She is owned by the Ore Steamship Corporation of New York, being the last of three vessels of this capacity and same general type to be built for this company recently at Sparrows Point.

The *Steelore* is arranged for carrying iron ore and when completed will be put into service for the transportation of ore from South America to the United States. She is of the same size and similar in construction to the *Bethore,* the large combination ore-and-oil vessel recently delivered at Sparrows Point to the Ore Steamship Corporation, but will be propelled by two Curtis-type turbines with Falk single reduction gears instead of by reciprocating engines.

The principal particulars of the *Steelore* are as follows:

Length, overall	571 feet 6 inches
Length, between perpendiculars	550 feet 1 inch
Breadth, molded	72 feet
Depth, molded	44 feet
Draft, loaded	32 feet 4 inches
Deadweight capacity	20,500 tons
Speed	11½ knots
Turbines	Curtis with single reduction gear
Type of boilers	Single end, Scotch
Number of boilers	3
Size of boilers	17 feet 6 inch diameter by 12 feet long
Kind of fuel	Oil
Type of oil burning equipment	Bethlehem (Dahl)

Japanese Electrically Propelled Naval Vessel Has Successful Sea Trials

The *Kamoi,* a 20,000-ton, 8,000 horsepower twin screw fuel ship of the Imperial Japanese Navy, and the first vessel of any navy other than the United States to be electrically propelled, successfully completed the builders' trials off the Delaware Capes on September 8. For thirty-six hours the *Kamoi,* manned by a crew from the yard of her builders, the New York Shipbuilding Corporation, and a Japanese crew under command of Captain T. Murase who will later take her over, was put through tests that brought into play every possible stress on all parts of her machinery and equipment and showed no signs of weakness.

First Installation of Synchronous Motors on Twin Screw Vessel

The electric drive equipment of the vessel, designed and installed by the General Electric Company, includes the use of synchronous motors for the first time in any twin screw vessel. Tests demonstrated that the Japanese ship is the most economically operated steam vessel of her size afloat. Her electrical propelling machinery gives unusual flexibility of control as well as economy of operation, and the mechan-

Launching of S. S. Steelore at Sparrows Point Plant of Bethlehem Shipbuilding Corporation, Ltd.

Japanese Fuel Ship Kamoi Leaving the Builder's Yard for Her Sea Trials

ical simplicity of the driving unit affords exceptional reliability.

There is practically no vibration to the vessel as was shown by the balancing of a nickel on edge on the foundation of the main turbine while the ship was under way. While the ship was going ahead at full speed the propelling machinery was reversed to ¼ speed astern in 19 seconds, after which the engines were brought up to full speed astern.

The *Kamoi* was built in this country instead of in the large shipbuilding yards of Japan in order that the Japanese might get electric drive which has been so highly developed in the United States on commercial and naval vessels.

Details of Machinery

The main propulsion unit consists of an 8,000 horsepower Curtis turbine generator, supplying power to two 4,000 horsepower synchronous motors directly driving the twin screw propellers. There are also two 400 kilowatt direct current turbine generators which supply the excitation current as well as power to operate the auxiliaries such as the main circulating pump, main condensate pump, sanitary pump, blower motors, steering gear, radio apparatus, ventilators and lighting equipment.

There is also a 625 kilowatt auxiliary alternator which can be connected to either of the auxiliary turbines in case of the failure of the main driving unit or any of the auxiliaries. This small generator will supply sufficient power to propel the ship at a speed of about seven knots.

The vessel is a coal burner, equipped with four Yarrow type boilers which have oil spray boosters attached to be used when high temperature is desired quickly.

Radio Equipment Is Unusual

The radio equipment is also of General Electric manufacture, consisting of a one kilowatt telephone and telegraph transmitter and two complete receiving sets, one with a range of 250 to 3,000 meters and the other from 250 to 30,000 meters. An unusual feature of the telephone installation is five extensions from the radio room connecting with the captain's cabin, engine room and other parts of the ship. By means of this equipment the captain can remove the receiver from the 'phone at any one of five stations and put in a call for the officer of another ship and carry on a conversation by radio much as he might from an office on a land telephone.

The ship has a normal tonnage of 19,500, is 495 feet long and has a beam of 62 feet. She has a draft of 28 feet and is equipped to carry approximately 10,000 tons of fuel oil.

Dock trials were held at Camden on August 25 and proved most satisfactory. After informal receptions on board the ship at Philadelphia and New York the *Kamoi* will proceed to Norfolk to take on fuel and will leave later on its trip to Japan.

Geared Turbine Cargo Steamer Built on the Wear for Dutch Owners

One of the latest vessels completed by The Wear Shipyard of William Gray and Company (1918) Limited, West Hartlepool and Sunderland, is the finely modeled geared turbine steamer *Modjokerto* built for Rotterdamsche Lloyd (William Ruys & Zonen, Directors, Rotterdam). The vessel was launched on February 27 of this year and successfully completed her sea trials on July 20.

The leading particulars of the vessel are as follows:

Length overall	451 feet 0 inches
Length on load waterline	449 feet 9 inches
Length between perpendiculars	433 feet 0 inches
Breadth, extreme	57 feet 3 inches
Breadth, molded	57 feet 0 inches
Depth, molded (to upper deck)	32 feet 10 inches
Depth to shelter deck	41 feet 0 inches
Load draft	29 feet 10¾ inches
Load displacement	16,436 tons
Load displacement coefficient	0.783
Tons per inch at load waterline	51.55
Deadweight tonnage (cargo and bunkers)	11,416
Under deck tonnage	6,181
Gross tonnage	8,404
Net tonnage	5,350

The vessel is of the shelter deck type without tonnage opening, and has been built under special survey to take the highest class of Lloyd's Register of Shipping. The Dutch Board of Trade Laws have also been complied with.

Although the vessel is built on the usual double bottom construction, several of the double bottom tanks have been specially constructed for the carriage of oil fuel. Heating coils have been fitted around the suction pipes in these

tanks to liquefy heavy oil. A deep tank of over 1,000 tons capacity is arranged directly abaft the engine room for the carriage of cocoanut oil, and a deep tank of similar capacity is provided immediately forward of the boiler room for the carriage of oil fuel. Side bunkers are also arranged for the carriage of oil fuel.

Accommodation is provided for the officers and engineers in steel houses built abreast the machinery casing, and a large steel house is arranged abaft No. 2 hatch, in which is the dining saloon and 5 staterooms. The captain's day and sleeping cabins, the wireless room and the wireless operator's cabin are situated over the dining saloon, and the chart house is fitted on top of the captain's house.

For the rapid handling of cargo, 14 steam winches by Messrs. Clarke, Chapman & Company, Ltd., Gateshead, are provided to work 14 derricks. A heavy derrick to lift 30 tons is stepped on the shelter deck directly abaft the foremast, and provision is also made directly forward of the mainmast for the transposing of this derrick.

The windlass is arranged to take a 2⅜ inch cable, and is of a very powerful type, the makers being Messrs Clarke, Chapman & Company, Ltd. The steering gear is of the Wilson-Pirrie type by Messrs. Hastie & Company of Greenock, and is operated by telemotor from the bridge.

An up-to-date electrical installation has been fitted throughout the vessel by the builders. Current is supplied at 65 volts by two dynamos of 16½ kilowatts capacity each, located in the engine room. The engine room auxiliaries are supplied by the Central Marine Engine Works.

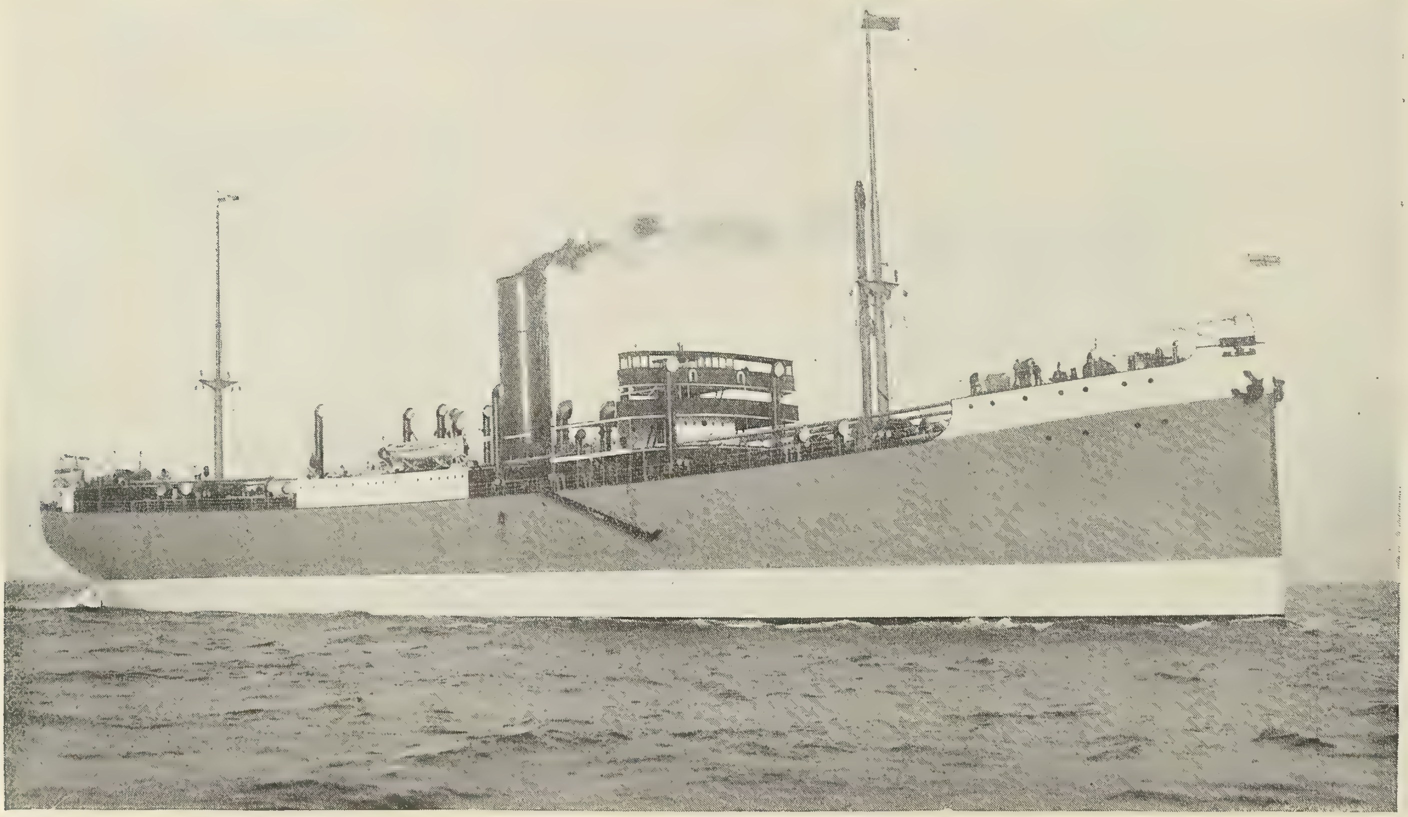
The propelling machinery, supplied by the Central Marine Engine Works, West Hartlepool, consists of one high pressure turbine of the impulse type, and one low pressure turbine of the reaction type, independently connected through flexible couplings to a set of double reduction gear wheels, which drive a four-bladed bronze propeller through a single line of shafting. Astern turbines, capable of developing 70 percent of the ahead power, are contained in the casings of the two ahead turbines.

Steam is supplied by four multitubular boilers, working under Howden's system of forced draft at a pressure of 225 pounds per square inch, and having a superheat of about 100 degrees F. The boilers are specially designed for burning coal or oil fuel.

Wrought Iron Produced by Mechanical Methods

Because of its desirable corrosion-resisting properties and resistance to vibratory stresses, wrought iron has always been in great demand industrially, its use being limited only by the output. The excessive labor and cost of hand puddling has largely been responsible for this condition, to overcome which many types of mechanical puddling furnaces have been designed at various times. The latest development in this connection is an oil-fired electrically operated furnace, which, working in conjunction with a new Titan rotary squeezer makes up the Titan process of wrought iron production, as carried out by the Titan Iron and Steel Company, Inc., Newark, N. J.

Physical, chemical and microscopic laboratory tests of wrought iron worked by this process indicate that all the desirable properties of hand-puddled wrought iron are retained and that the uniformity of structure is increased. In addition, the distribution of slag contained is more uniform, thus insuring maximum protection against rust and corrosion. Metallurgically, the Titan mechanical process of puddling is practically the same as the old hand process; that is, the stages of clearing, boiling, dropping and balling are carried on in a similar manner in both processes. The new type squeezer makes possible the removal of the correct amount of excess slag from the larger mass of wrought iron produced in the mechanical puddle furnace in one heat. Oil firing is an advantage in the process as well and makes possible quantity production of the metal on an economical basis.



Geared Turbine Cargo Steamer Modjokerto

Reconditioned Steamship H. F. Alexander Leaving the Sun Shipyard

Passenger Accommodations of the H. F. Alexander

U. S. S. Columbia, Formerly Army Transport Great Northern, Reconditioned at Sun Shipyard for Admiral Line Passenger Service

FEW vessels in the American merchant marine have had a more varied or interesting career than has fallen to the lot of the 23-knot, triple screw passenger steamship *Great Northern,* which, with her sister ship, the ill-fated *Northern Pacific,* was built eight years ago by the William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa., for the San Francisco-Astoria service of the Spokane, Portland and Seattle Railway Company, a subsidiary of the Great Northern Railway Lines. She is the largest direct turbine-driven passenger vessel built in the United States and with the graceful lines of her hull, ample freeboard and well-protected decks provides the qualities of speed, strength and seaworthiness so desirable for the fast coastwise service for which she was originally designed.

With the entrance of the United States into the World War the *Great Northern* was called into service as an army transport and carried upwards of 35,000 men to the battlefields of Europe, making round trips in a fraction over twelve days. After the war the vessel was again in service in Pacific waters for a brief period after which she was taken over by the Navy, rechristened the *Columbia* and used as the flagship of the Atlantic fleet. On March 2 of this year the *Columbia* was brought to the yard of the Sun Shipbuilding Company at Chester, Pa., by the Admiral Line to be reconditioned as a first-class passenger liner for the coastwise service of her new owners between Seattle, Wash., and San Pedro, Cal.

Within ten weeks the transformation of the vessel was complete, the work involving the complete rebuilding of her four principal decks. Two hundred and fifty-four staterooms were built, with their fittings, together with about fifty special de luxe suites, officers' quarters, dining room, lounge, new heating and ventilating systems and many other changes. Some idea of the nature of this work can be gained by an inspection of the interior views of the *H. F. Alexander,* as the vessel is now named in honor of the president of the Admiral Line, which are reproduced on the following pages through the courtesy extended by the Sun Shipbuilding Company.

Plans for reconditioning the vessel were furnished by Theodore E. Ferris, naval architect, New York, who personally supervised the work. On the "A" or promenade deck, which is flush from the stem to a point near the stern, are the main public rooms including the lounge, observation room, music room, main lobby, smoking room and deck veranda. On the deck below is a woman's writing room while the main dining room, with galley, pantry, etc., is located on the upper deck. The style of decoration and furnishing in the public rooms is varied and pleasing, each being especially adapted for its purpose. In the lounge, smoking room and the owner's suite fireplaces form an attractive feature of the furnishings.

General Characteristics of Vessel

With her commodious and luxurious accommodations the *H. F. Alexander* offers the most modern facilities for swift transportation by water along the Pacific coast. The vessel has a length overall of 524 feet and between perpendiculars of 500 feet. Her beam is 63 feet and her depth to the promenade deck 50 feet 8 inches. She has a deadweight carrying capacity of 2,185 tons on a draft of 21 feet. Her gross tonnage is 8,255 tons. Propulsion is by Parsons turbines arranged on three shafts, the high pressure turbine driving the center shaft and the low pressure turbines the wing shafts. At her designed speed of 23 knots the propellers turn at 325 revolutions per minute. Steam is supplied at 220 pounds per square inch by 12 oil-fired Babcock and Wilcox watertube boilers working under the closed stoke hold system of forced draft.

Additional Repairs Required

Just after the *H. F. Alexander* had been turned over to the Admiral Line and was on her way to New York, preparatory to her sailing for her station on the Pacific coast, the vessel was in collision with the British steamer *Andree* causing extensive damage to her bow. Returning to the Sun yard on May 22 the ship was placed in drydock for repairs. The damage both above and below the waterline was so extensive that it was necessary to replace a considerable portion of the stem and main keelson and twenty-seven frames and plates. The work was rushed day and night without interruption and on May 29, two days ahead of the scheduled time, the job was completed and the vessel was ready to take on her fuel oil and resume her service.

The Golden Gate, Which Runs Between San Francisco and Sausalito in San Francisco Bay, Is the First Diesel Engine Electric Ferryboat to Go Into Operation

Electric Drive Adopted in a New Field

Application to Double Ended Ferryboats—Types of Installation, Power Requirements and Advantages Described

By W. H. Wild*

THE effective service rendered in recent years by electrically propelled vessels of many different types and sizes is one of the chief factors which has just led to the extension of the system into a new field—the double ended ferryboat. News dispatches have announced the placing of several orders for electric equipment for boats of this class in New York and San Francisco, and one of the vessels went into service in the harbor of the latter city this summer. There are now seven ferryboats either running or in process of building, utilizing both the Diesel engine and turbine electric method of propulsion. Three boats have been contracted for in New York with turbine electric drive and four in San Francisco equally divided between Diesel engine electric and turbine electric drive.

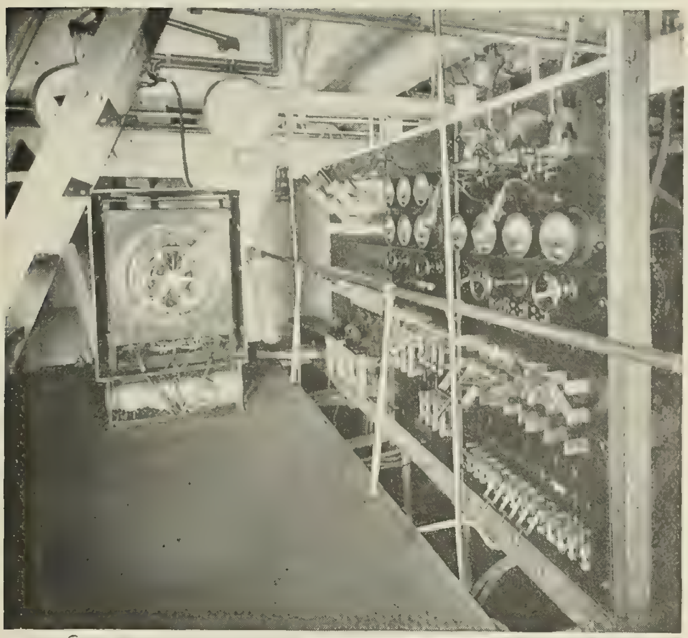
Intended for Fast Service

The San Francisco boats are intended for fast service across the Bay, being 220 feet long, overall, and equipped with two 500 horsepower Werkspoor Diesel engines, each driving a 360 kilowatt, 250 volt direct current generator. The power from the generators is delivered to two 750 horsepower, 500 volt shunt wound motors, one on each propeller shaft. The New York Harbor boats are much larger, and will run between Staten Island and New York City. Their propulsion equipment consists of one 2,200 shaft horsepower, 2,300 volt, 3 phase turbine generator supplying power to two 2100/100 shaft horsepower, 2,300 volt, 3 phase induction motors, one on each propeller shaft. Both types of boat are designed to give rapid service on runs about five miles in length.

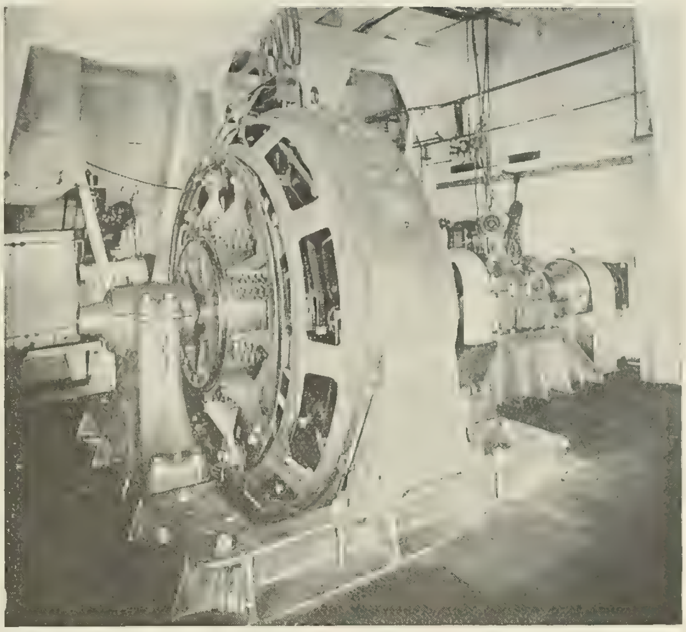
The dominating idea behind the application of electric drive in both instances was to give rapid and efficient service with the greatest economy possible. The performance of various ocean going ships equipped with both classes of electric drive have demonstrated its superiority on a number of counts. Among the most important of these are reduced fuel consumption, better maintenance of the desired speed under varying conditions and increased maneuvering ability. All of these are of equal importance in the case of ferryboats, especially those operating on runs of considerable distance through crowded harbors where strong current may be encountered.

Tests conducted over the past twenty years on double

*Marine Department, General Electric Company, Schenectady, N. Y.



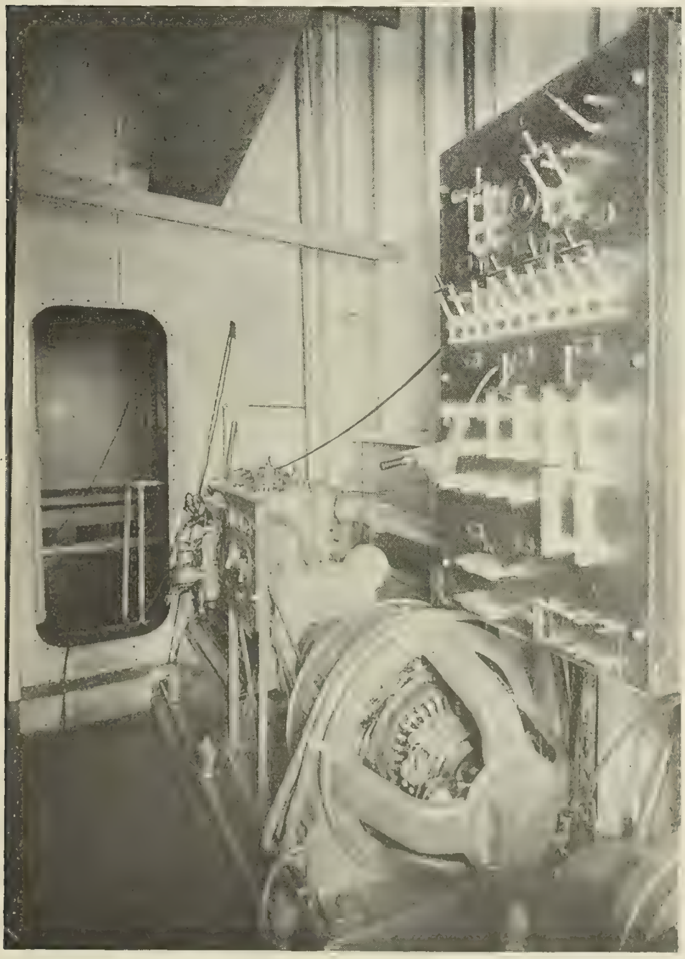
Switchboard Gallery in the Engine Room, Showing Control and Meter Panels and Control Rheostat, on the Golden Gate



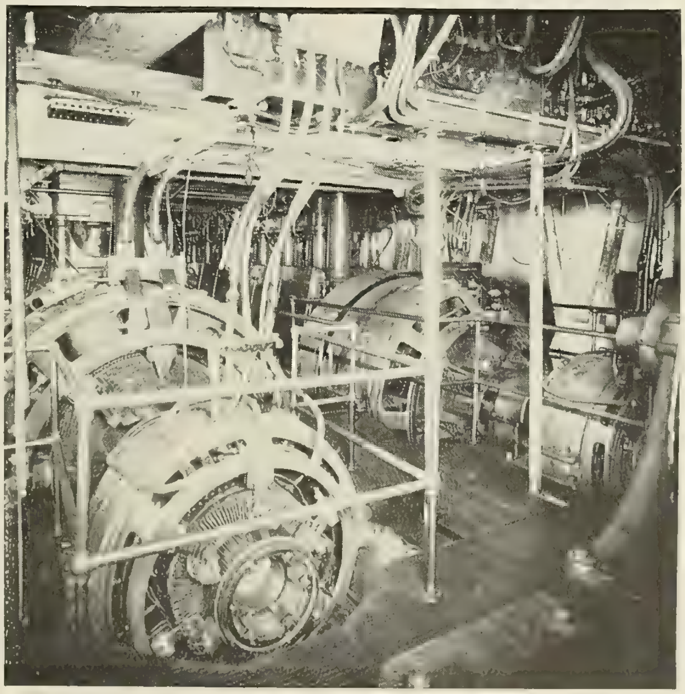
One of the Golden Gate's 750 Horsepower, 500 Volt, Shunt Wound, Direct Current Propeller Motors. Two of These Are Installed, One at Each End of the Engine Room

ended ferryboats have established two salient facts in connection with their design and operation. First they must have propellers fore and aft, both for maneuvering, and changing direction quickly, and second, the most efficient method of propulsion is by means of the stern propeller. Until the inception of electric drive, the problem of how to effect the concentration of power on the stern propeller remained without a really satisfactory solution. The basis for such a statement is the result of tests made on steam ferryboats, which showed high percentages of power loss, due to the bow propeller. As a result, in most cases the boats had to be "overpowered" considerably in order to insure the desired speed and maneuvering ability.

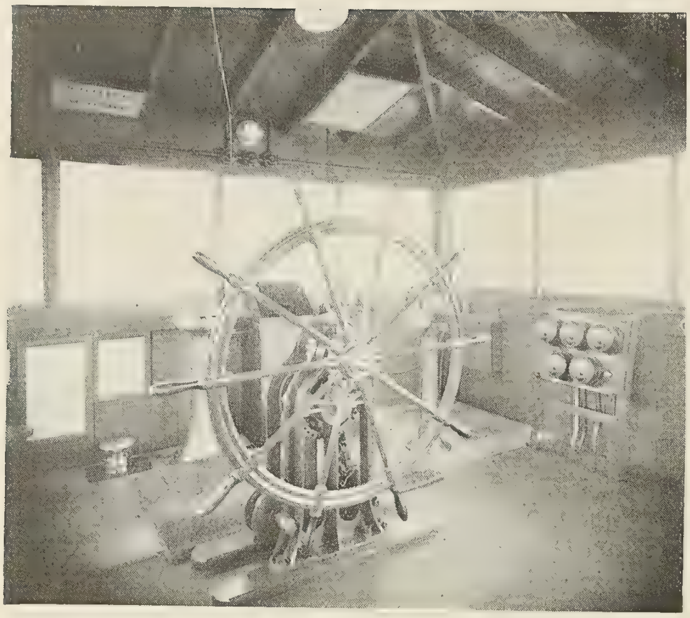
On the other hand, the flexibility of electric drive makes the solution of the power concentration problem comparatively simple. By using two motors, each individually con-



One of the Diesel Engine Driven Auxiliary Generators on the Golden Gate Which Supply Power for the Pumps, Current for Lighting, etc.



Engine Room of the Golden Gate, Showing the 500 Horsepower Werkspoor Diesel Engines and 360 Kilowatt, 250 Volt, Direct Current Generators and Exciters Which Supply Power to the Propelling Motors

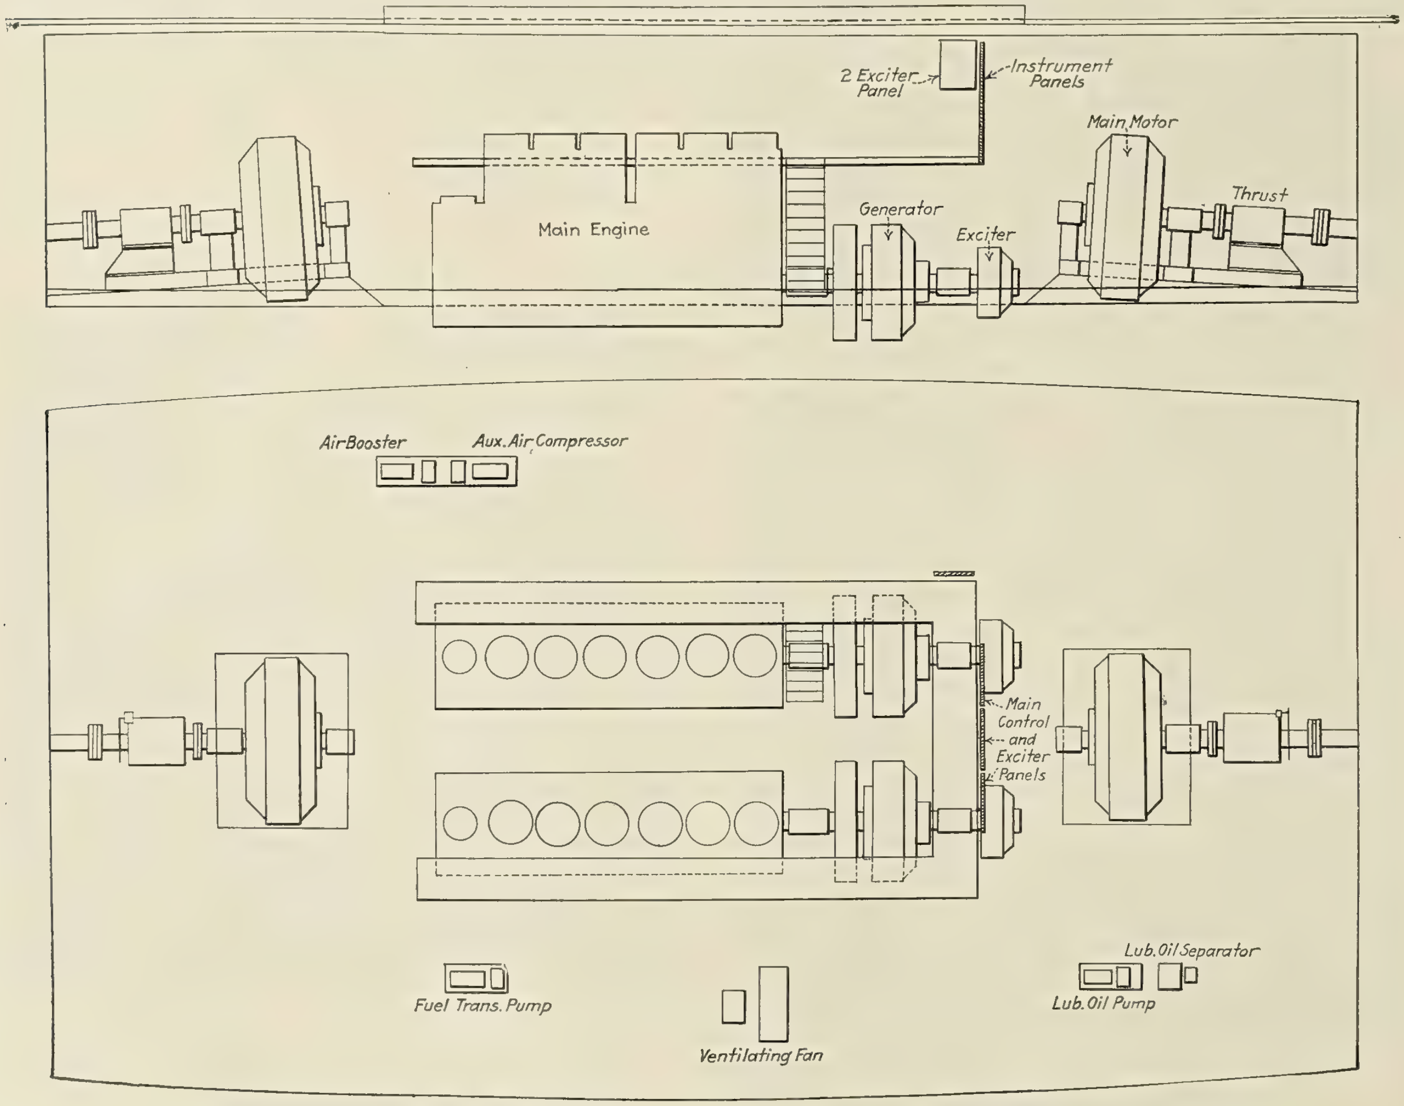


Interior of Pilot House of the Golden Gate, Showing the Steering Wheel and the Pilot House Meter Panel

nected to one of the propellers by a short shaft, and mechanically independent of each other, the power can be distributed and concentrated where it is needed, and any speed or direction of rotation obtained on either propeller, irrespective of that of the prime mover, be it turbine or Diesel engine. Furthermore, the bow propeller can be turned over at such a speed that the power saved in driving it electrically is about equal to the total electric losses. This fact was demonstrated by a series of tests, described in the December, 1920, issue of Marine Engineering and Shipping Age by Commander S. M. Robinson, U. S. N. On the Diesel engine electric ferryboats this "pilot motor" speed is obtained by strengthening the field of the forward motor. After the proper speed has once been found, it can be made the subject of an automatic setting through the control panel. On the turbine electric boats, the induction motors driving the propellers are designed for operation with two sets of poles, provision for shifting from one to the other being made in the control panel.

Maneuvering Ability Increased

Of the other features mentioned in connection with electric drive, the one of next importance in ferryboat practice, is probably maneuvering ability. Such a boat, operating as it does in crowded harbors, must be under absolute control, not only as regards forward speed, but for stopping and reversing. With electric drive, since only the speed of the motor must be altered, stopping and reversing are both only a matter of seconds as has been thoroughly demonstrated in the case of the electric ship. In addition, the control may be located in the most advantageous position—in the pilot house itself, if desired, so that the ease with which the boat



Longitudinal Section and Plan of Engine Room of San Francisco Diesel-Electric Ferryboat

may be handled in emergencies is greatly increased. Maneuvering ability is also a decided asset in boats that are required to dock as rapidly and smoothly as are ferryboats.

The character of the propelling apparatus and the method of connecting the actual driving elements to the source of power are such that not only can the units be mounted so as to conserve the greatest amount of space, but so as to give the greatest of efficiency as far as power is concerned, since the power is applied just where it is needed. It also facilitates the use of electrically driven auxiliaries of various sorts, and the electric auxiliary is even more efficient on ships operating on an intermittent duty cycle than it is on cargo ships. All things considered, it is a safe prediction that the success experienced by the electrically driven ship will be equalled by that of the electrically driven ferryboat, and that the number of the latter will increase rapidly, as the realization of their advantages becomes more widely spread.

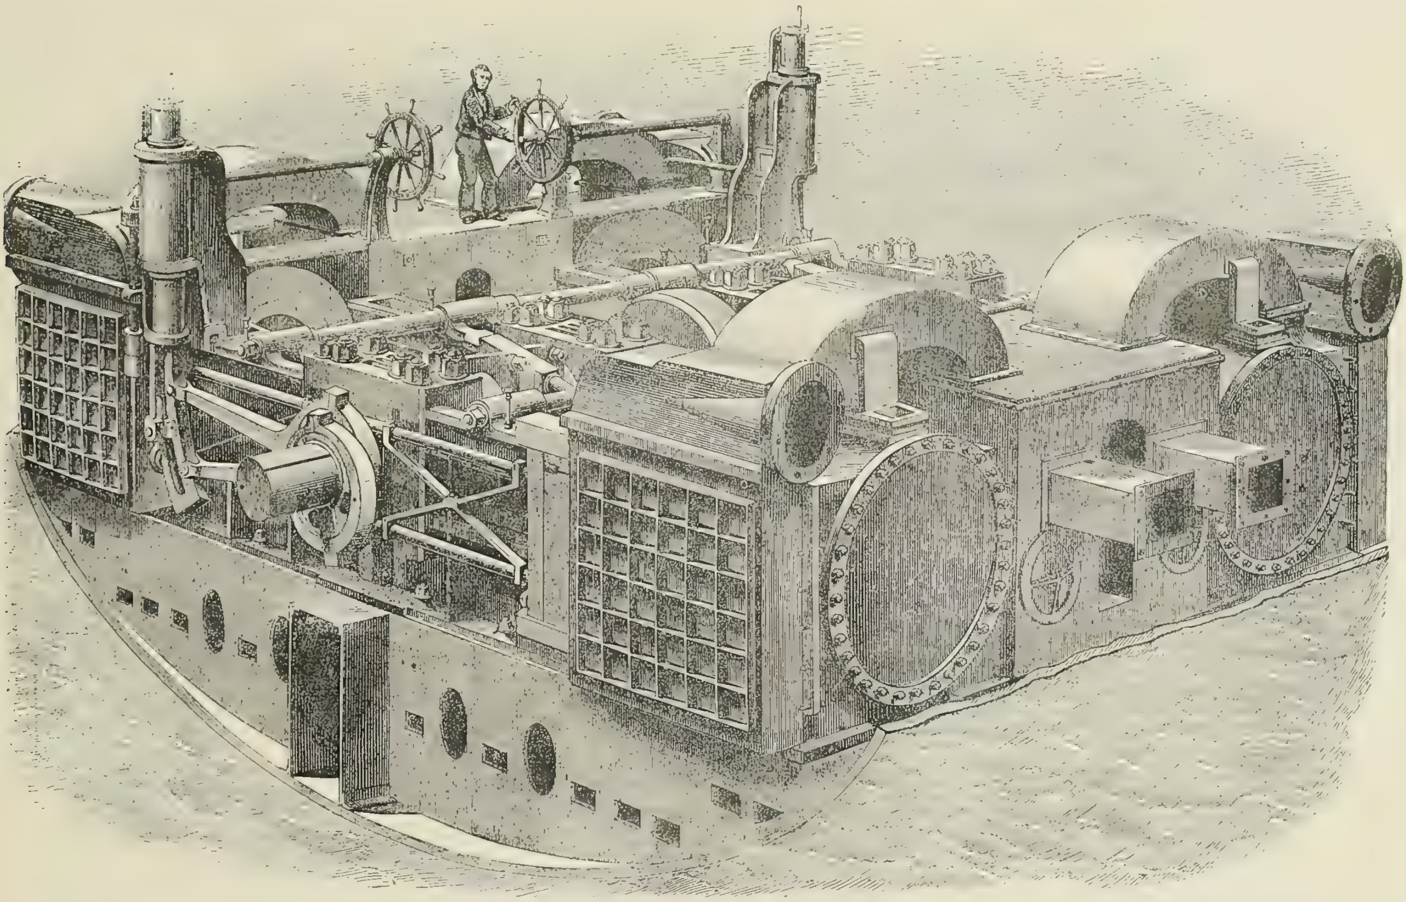
Exporters to Discuss Shipping Bill

At the annual convention of the American Manufacturers' Export Association, which will be held on October 26, special attention will be given to a consideration of the Administration Shipping Bill which is slated to come up for action in Congress next month. During the convention the association will hold a merchant shipping session at which Homer L. Ferguson, president of the Newport News Shipbuilding and Dry Dock Company, will preside. It is understood that the list of speakers at this special session will include W. A. Harriman, head of the United American Lines; Edward C. Plummer, of the United States Shipping Board, and other important speakers.

How a Famous Marine Engine Was Described 65 Years Ago

What "The Illustrated London News" of May 23, 1857, Had to Say About the "Screw Engines" of the Steamship Great Eastern

When the famous steamship *Great Eastern,* designed by John Scott Russell, was under construction in Great Britain 65 years ago great curiosity naturally prevailed regarding the details of her hull and machinery and speculation was rife as to her probable performance when completed. She was to have an overall length of nearly 700 feet, which was more than twice the length of the *Great Britain,* the last large ship built, which in turn was 100 feet longer than any existing warship. Among her other spectacular features, besides size, she was to have a double hull, longitudinally framed and strengthened with two longitudinal bulkheads. Furthermore, she was to have three distinct means of propulsion—sails, paddle wheels and screw.



(Reproduction of Wood Cut from The Illustrated London News, May 23, 1857)

The Screw Engines of the "Great Eastern" Steamship, by James Watt and Company

The screw engines were manufactured by Messrs. James Watt and Company and as described in *The Illustrated London News* of May 23, 1857, were "the largest and most powerful engines ever yet constructed." This article is reproduced below not only because of the data which it contains regarding this early example of marine steam machinery but also because of the author's comments on the probable performance of the vessel. These predictions turned out to be at wide variance with the results actually achieved as she never made over 15 knots with both screw and paddle wheels. The article is also of interest because of the manner

in which it is written which is typical of the style of technical writing at that time. The article is as follows:

"There are four cylinders, each of eighty-four inches diameter, for driving the screw of this vessel. The length of the stroke is four feet, and the makers reckon that the engines will make about forty-five revolutions per minute. The cylinders lie on their sides, as is a common arrangement in screw engines: the piston-rods protrude through the ends of the cylinders nearest the central shaft on the end of which the screw is hung, and the connecting rods attached to the piston-rods engage cranks in the screw shaft and turn it round just in the same manner as the arm turns round a grindstone. The pistons, which are solid plugs, pressed by the steam backwards and forwards in the cylinders, communicate their reciprocating movement through the medium of the piston-rods to the connecting rods; and in this way the screw shaft is turned round, and the vessel is screwed forward in the water just as a screw auger turned round advances in a piece of wood, or a corkscrew in a cork.

"The pressure of the steam in the boilers is 25 pounds on each square inch. The total heating surface in the boilers of the screw engines is about 30,000 square feet. The nominal power of the screw engines is 1,700-horsepower; and, if they work up to four times their nominal power, which is not an unusual performance, the actual indicated power will be 6,800-horsepower. The area of that part of the cross section of the ship which falls beneath the water line is about 2,000 square feet, when the vessel is drawing 28 feet of water. The estimated amount of water evaporated by the boilers of the screw engines per hour is 3,150 cubic feet, and the area of the grate bars is 1,218 square feet.

"The screw is formed with four blades. Its diameter is 24 feet, and its pitch or the distance which it would advance during each revolution if it worked in a solid body, like a corkscrew penetrating a cork, is 44 feet.

"In addition to the screw, the vessel is supplied with paddle-wheels driven by four engines, each of 72 inches diameter of cylinder and 14 feet stroke, and rated collectively at 1,000 nominal horses' power. If we suppose that these engines also work up to four times their nominal power, it will be quite safe to reckon the actual power effective in propelling the vessel at 10,000 indicator horses' power.

"It is a question of much interest to determine what amount of speed this power will impart to the vessel. Messrs. James Watt and Company's anticipation is that the speed of the vessel will be about seventeen miles an hour; and from that to eighteen miles seems to be about the limit engineers have hitherto predicted. But we believe that these anticipations fall very far short of what the real speed will be, and which we do not hesitate to predict will turn out to be between twenty-four and twenty-five miles per hour. No allowance has been made in the existing computations of the speed for the great size of the vessel; yet it is well known that large vessels are more easily propelled, relatively with their proportion of power than small vessels, as is popularly manifested at every yacht race, where an allowance of time is made for the smallness of the vessels; and, in France, where the variation in the resistance consequent upon size has been carefully investigated, it is found that the velocities attained by similar vessels, but of different sizes, vary as the square root of any linear dimension. A vessel, therefore, of twice the length of the *Himalaya*, and with four times the sectional area and four times the power, will be faster than the *Himalaya* in the proportion of the square root of 2 to the square root of 1, or 1.4 times; so that the *Great Eastern*, had she been built of the same size as the *Himalaya*, has proportion of power enough to attain speed of seventeen miles an hour, she will, with her existing dimensions, be 1.4 times faster, or go 23.8, nearly 24, miles an hour. By reckoning the resistance as proportionate to the immersed perimeter, the speed comes out as twenty-three miles. At the increased speed, however, the engines, if duly supplied with steam, will develop more power than at the computed speed, so that, in all probability, a speed of close upon twenty-five statute miles per hour will be attained.

"The existing mode of estimating the resistance by the area of the immersed midship section is erroneous, except in the comparison of vessels of similar dimensions. It is, in putting into motion a column of water by friction that the power of the engine in well-formed vessels is chiefly expended, and the magnitude of this column depends, not upon the area of the cross section, but the amount of rubbing surface it offers to the water. The resistance of rivers is measured by the length of the outline in the cross section of the bed; and large rivers, with the same declivity, run much more swiftly than small. In like manner it should be by the immersed perimeter of the cross section that the resistance of ships should be measured, and when this is done it will be seen how very much less is the proportionate resistance of large vessels. A speed of thirty miles an hour in steam vessels is not, we are persuaded, very distant of attainment. Nor does it appear probable that at high velocities the resistance will be found to increase at the same rapid rate as at low. It is the adhesion of the water which at low speeds consumes power, and this adhesion moves the contiguous water because it is easier to do so than for the vessel to pass over it as if rubbing on a solid. But as with every increase of speed a thicker film of water adheres, the resistance occasioned by moving this mass of water will gradually become so great that it will be easier for the vessel to rub over the film than to drag it with her; and when this takes place the friction will thereafter follow the law which obtains in the case of solid bodies, and the resistance will no longer increase as the square of the velocity. At what point the equilibrium between the adhesion and the friction will be attained is a question which experiment must determine; but the apprehension of the fact that it will be attained at some determinable velocity gives warrant for the expectation of higher rates of speed in steam navigation than has heretofore been thought possible of attainment.

"The success of the *Great Eastern* as a commercial enterprise depends mainly upon her capability of realizing some such speed as twenty-five miles an hour. With such a speed she can command employment on any station, and can also compel the Government to give her a subvention for carrying the mails. With such an ordinary rate of speed as sixteen or seventeen miles an hour her commercial success is far more problematical. Moreover, with so large a cost a vital element is time. She must neither be a day longer on the voyage nor a day longer in harbor than is absolutely indispensable, but must be driven at such a rate as to make the capital productive. Taking the cost at £500,000, and the interest and depreciation at only ten percent upon this amount, we have about £1,000 a week of expense from this source alone. The actual amount chargeable to this item will be very much more than is here reckoned, but the approximation is sufficient to show the importance of attaining and maintaining high speeds on this sole inducement. Of the twenty-five miles an hour we have no doubt whatever, if there is the steam; and the boilers will produce the steam if the draft is sufficient. In most steam-vessels the draft is too sluggish, and the heat in the furnaces is not sufficiently intense. It has been proposed to use anthracite coal in the *Great Eastern*, but this is an experiment, and Welsh coals can be more safely depended on. The bridges at the ends of the furnaces should be high, so as to retain a high temperature in the furnace, which both consumes the coal more effectively and compels more of the heat to enter the water in the region of the furnaces—thus leaving less work for the tubes or flues to do. There should be good steam jets in the chimneys, so as to ensure a strong draft. With these simple precautions we have no fear of the speed; and, as the vessel is the strongest vessel ever sent to sea, there can be no doubt of her complete seaworthiness. The auxiliary engines for turning the screw round when the screw engines are not at work are, in our judgment, unnecessary; and every engine or piece of machinery not absolutely necessary is a complication and disparagement. Simplicity and fewness of parts to look after and keep in repair is a most important desideratum in steam navigation. Transcendentalism will not work in such a sphere, and in our judgment some of the refinements introduced into the *Great Eastern* might have been advantageously omitted. But in all its main features there can be no doubt whatever of the soundness of the design or of the excellence of the execution, while we believe that the performance of the vessel will exceed everything which the most sanguine supporters of the enterprise have ventured to anticipate, and will far outrun the prognostications which engineers, overlooking the element of size, have hitherto formed."

Broken Propeller Blades on 9,500-Ton Vessels Replaced With Aid of 4,500-Ton Floating Dry Dock

During the month of July two of the Matson Navigation Company's single screw steamers, the *Manukai* and *Manulani*, each of 9,500-tons gross register, arrived in Honolulu in crippled condition, due in both cases to the same mishap—the loss of one blade of its propeller. The nature of the accident, which was identical in both cases, is shown in Fig. 3.

The contract for replacing the broken propeller blade on each of these steamers was awarded to the Honolulu Iron Works and the work was carried out on the 4,500-ton floating dry dock of the Inter-Island Steam Navigation Company of Honolulu. This dry dock, which has wooden pontoons and steel wings, was built in 1913 from designs by William T. Donnelly, consulting engineer, New York. Al-

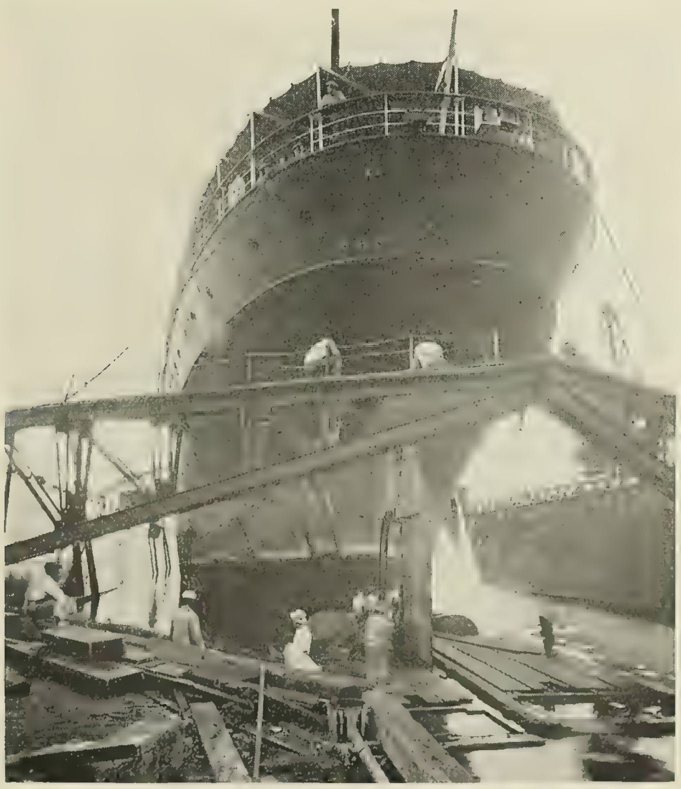

Fig. 2.—Replacing Broken Propeller Blade of S.S. Manukai on 4,500-Ton Floating Dry Dock at Honolulu

Fig. 3.—Broken Propeller Blade on the Manukai. Identically the Same Mishap Occurred on the Manulani

though the dock has a lifting capacity of only 4,500 tons and its length over the wings is only 300 feet, nevertheless it was found possible, as shown by the illustrations, to lift the vessels, which in each case are over 9,500 tons gross register, and have a length of 480 feet, sufficiently to expose the propeller so that the broken blade could be replaced.

In the case of the *Manukai,* which had on board at the time of docking 3,200 tons of cargo, making a docking tonnage of 12,747, the propeller blade was replaced in two hours and 15 minutes. The work on the *Manulani,* which had on board 4,400 tons of cargo, giving a docking tonnage of 13,956, was finished in two hours flat.

Federal Shipyard Building Nine 80-Ton Scotch Boilers

Largest Marine Boilers Constructed in New York District to Operate at 225 Pounds Working Pressure

MANY special features of construction, due to their size, and the weight of materials used, have been incorporated in the nine single ended Scotch marine boilers which are now under construction for the Luckenbach Steamship Company at the Federal Shipbuilding Company's plant, Kearny, N. J. These boilers, which have a diameter of 17 feet 6 inches and a length of 13 feet, are intended for installation in ships of the Luckenbach fleet, which are being reconditioned at the Baltimore plant of the Bethlehem Shipbuilding Corporation. The boilers will be used to replace watertube boilers which were removed from the vessel.

Construction of the very highest quality has been maintained to meet the requirements of the United States Steamboat Inspection Service, the American Bureau of Shipping and Lloyd's Register of Shipping. The boilers are designed to burn oil under the heated forced draft system. The fact that the dry weight of each boiler will be approximately 80 tons gives an excellent idea of their unusual size. The weight of the shell alone with butt straps is about 67,000 pounds, while 3½ tons of rivets are used in each boiler. In the case of the butt straps, the rivets used are 8⅝ inches long and weigh 8¼ pounds each. The largest shell plate is 243⅛ inches by 144¼ inches by 2 inches and weighs 10 tons while the bottom heads are cut from plates 232⅛ inches by 164¼ inches by 1-3/32 inches and weigh 6 tons. The shell is made in one course and three plates are used in the circumference. The longitudinal seams are of double butt strap construction with both the inside and outside straps of equal width. The outside strap is 2 inches thick, as in the case of the shell plate, while the inside strap is 1¾ inches thick. Rivets 1⅞ inches in diameter are driven through holes drilled to 1-15/16 inches diameter. The efficiency of the plate used in the straps is 82.5 percent; the rivet efficiency 107.8 percent; and the combined plate and rivet efficiency 86.3 percent.

General Characteristics

In order to increase the life and efficiency of the boilers in service, the scantlings have been kept well in excess of the requirements of the classification societies. Special attention in this connection is called to the thickness of the outer butt strap, mentioned above, which was made 2 inches thick to conform with the specifications and is 23 percent

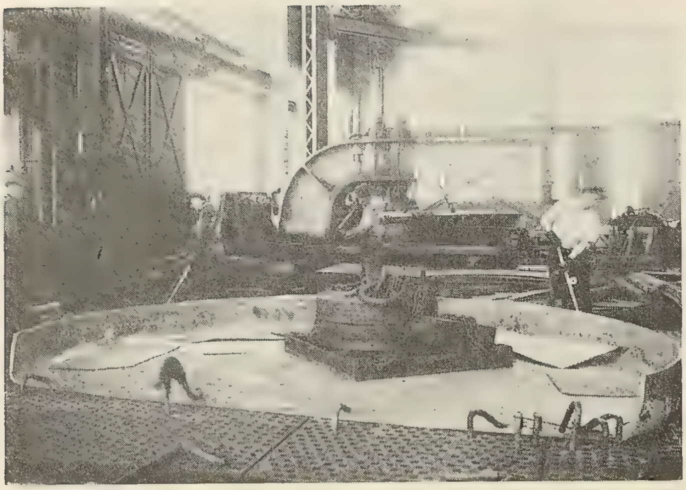

Fig. 3.—Furnacing and Annealing Boiler Head

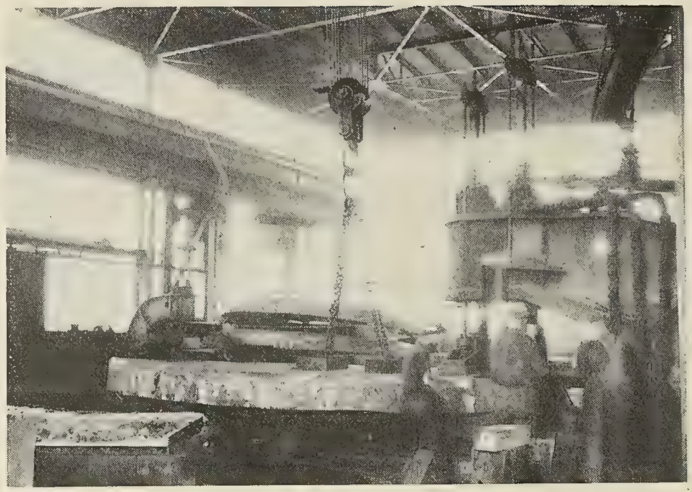

Fig. 5.—Flanging Lower Head

in excess of the requirements. Because of the extreme proportions thus provided, ample space has been available for a wide spacing of tubes and an unusually wide space between the lower banks of tubes and the furnaces. This feature, because of the possibility of adequate maintenance and cleaning facilities, will insure a high operating efficiency of the boilers at all times. The steam space ratio of 0.29, especially for a boiler of this size, gives a very large steam space and will tend to insure against priming. As a further preventative against priming in case of the ship rolling, two swash plates are provided by the installation of a 9-inch by 3½-inch bulb angle on each side of the shell above the waterline.

Each combustion chamber is supported from below by a stool or saddle riveted to the shell plate. These saddles are built up of 2½-inch by 2½-inch angles and steel webs of ⅝-inch plate so installed as not to interfere with access from the manholes and so that the combustion chamber is free to move.

All flange plates have large radii, those of the main heads being about 5 inches inside of the plate. Care in all cases has been taken that the shell plates and butt straps are circular in form and that the top of the back connections are well rounded at the corners.

There are three 12-inch by 16-inch manholes located in the lower back head between the furnaces and one near the

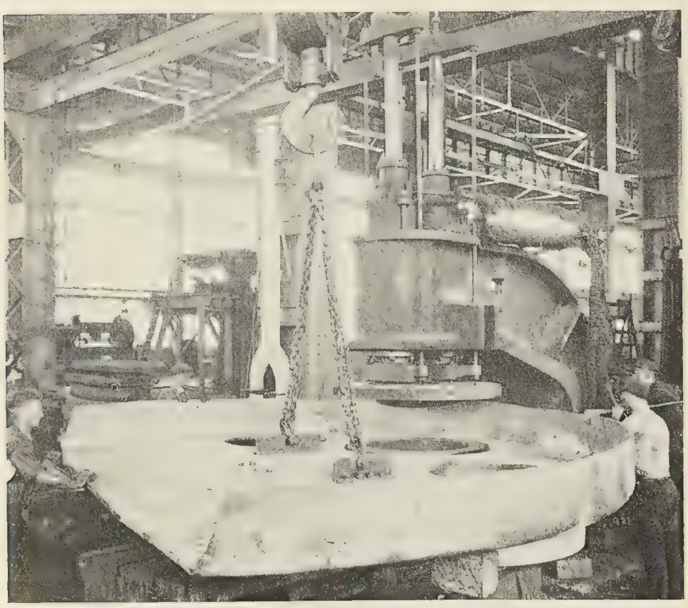

Fig. 4.—Flanging Furnace Holes in Front Head

top of the back head in the shell. The top heads are well braced with twenty-four 3-inch steel stays and the wide spaces in the lower heads and combustion chamber tube sheets are supported with eight 2½-inch crowfoot stays.

All tubes are of cold drawn seamless steel annealed and are 2½ inches outside diameter. The ordinary tubes, of which there are four hundred and sixty-two, are of No. 10 B. W. G. material, while the one hundred and forty-four stay tubes installed are 5/16-inch thick. The ordinary tubes are swelled 1/16 inch in diameter on the front end and the stay tubes upset and threaded on both ends. The tubes have a length of 8 feet 8 inches over tube sheets and are expanded and beaded over on both ends.

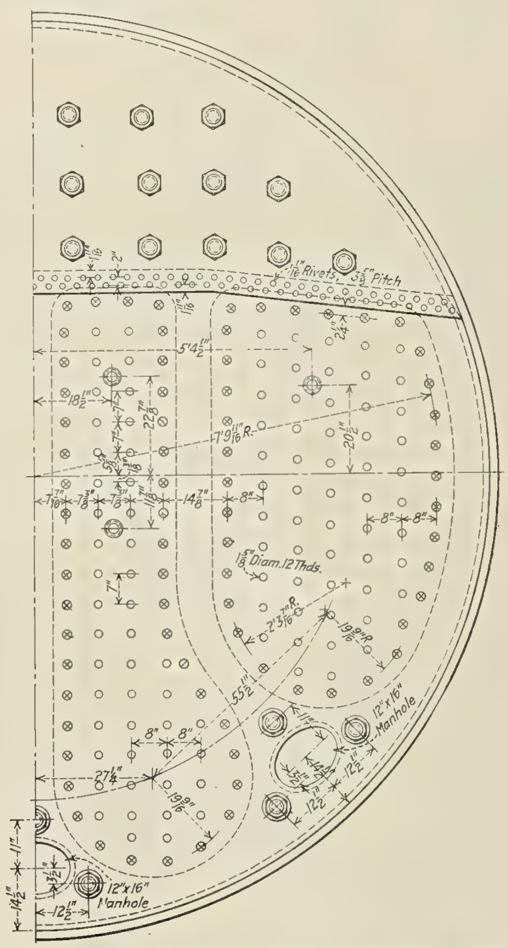

Fig. 6.—Details of Back Head of 80-ton Boiler

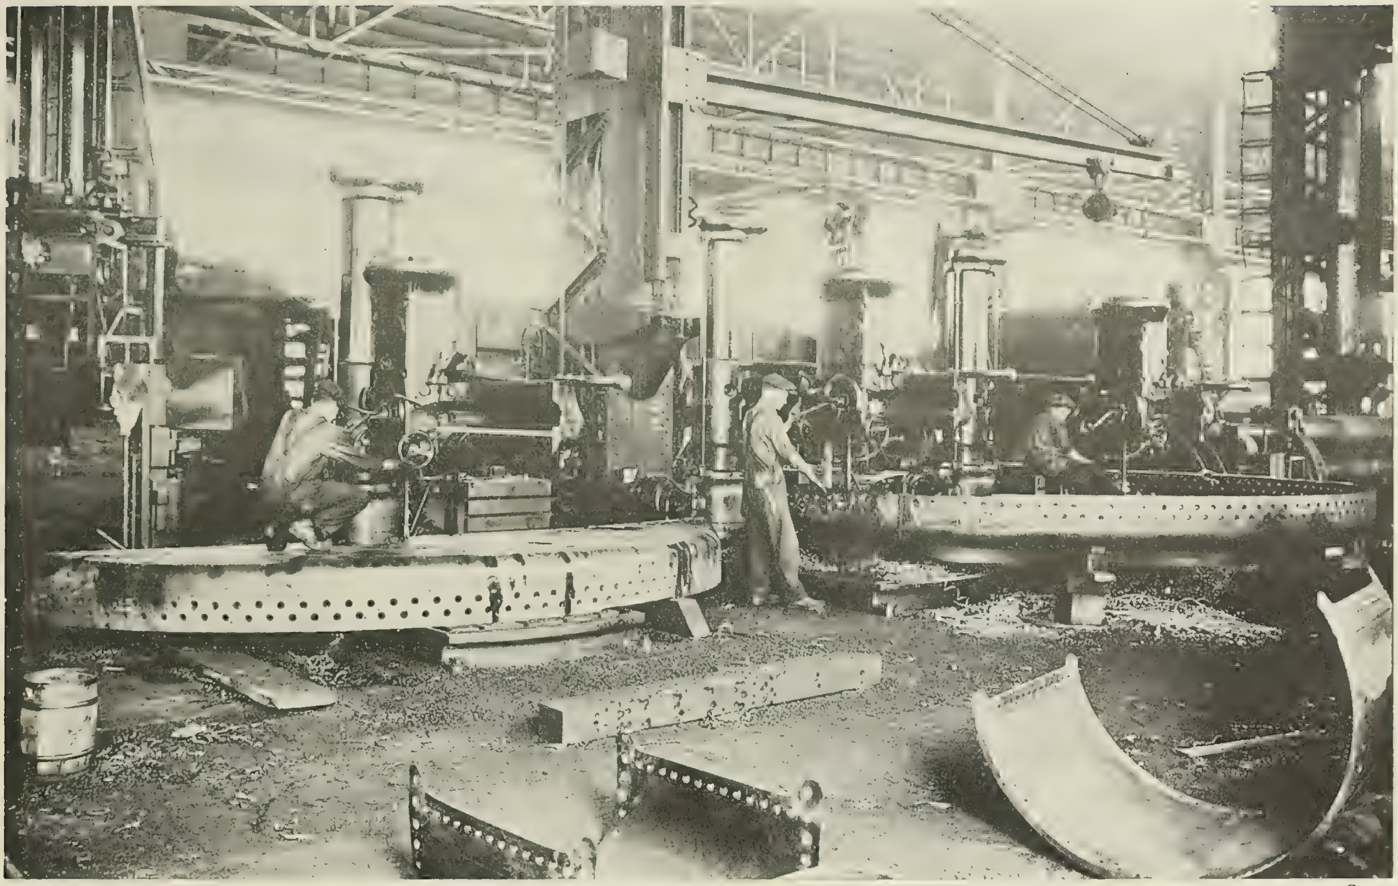

Fig. 7.—Cutting Tube Holes and Stayholes in Boiler Heads

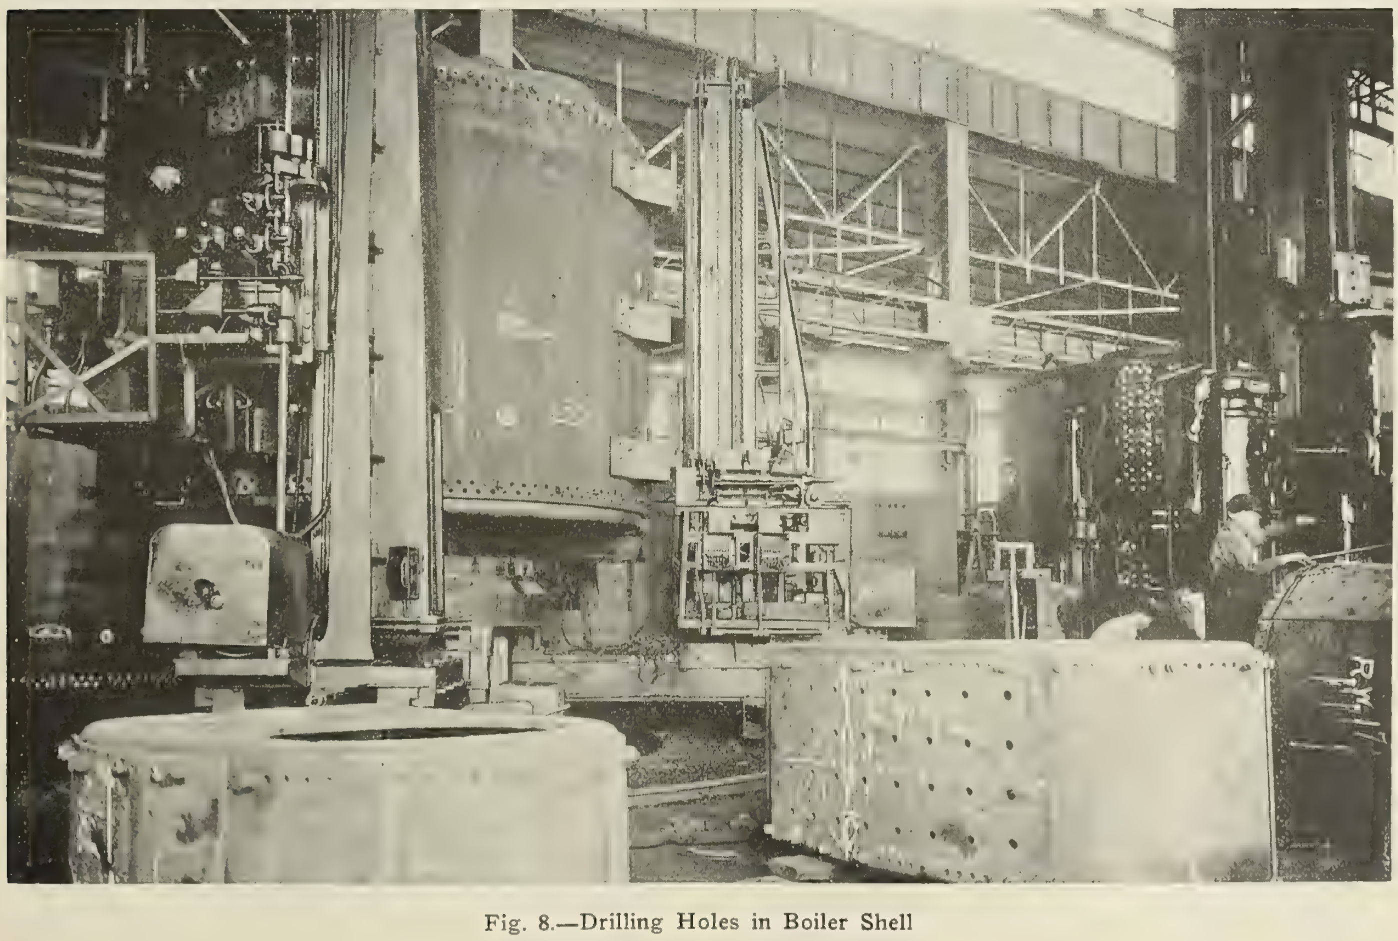

Fig. 8.—Drilling Holes in Boiler Shell

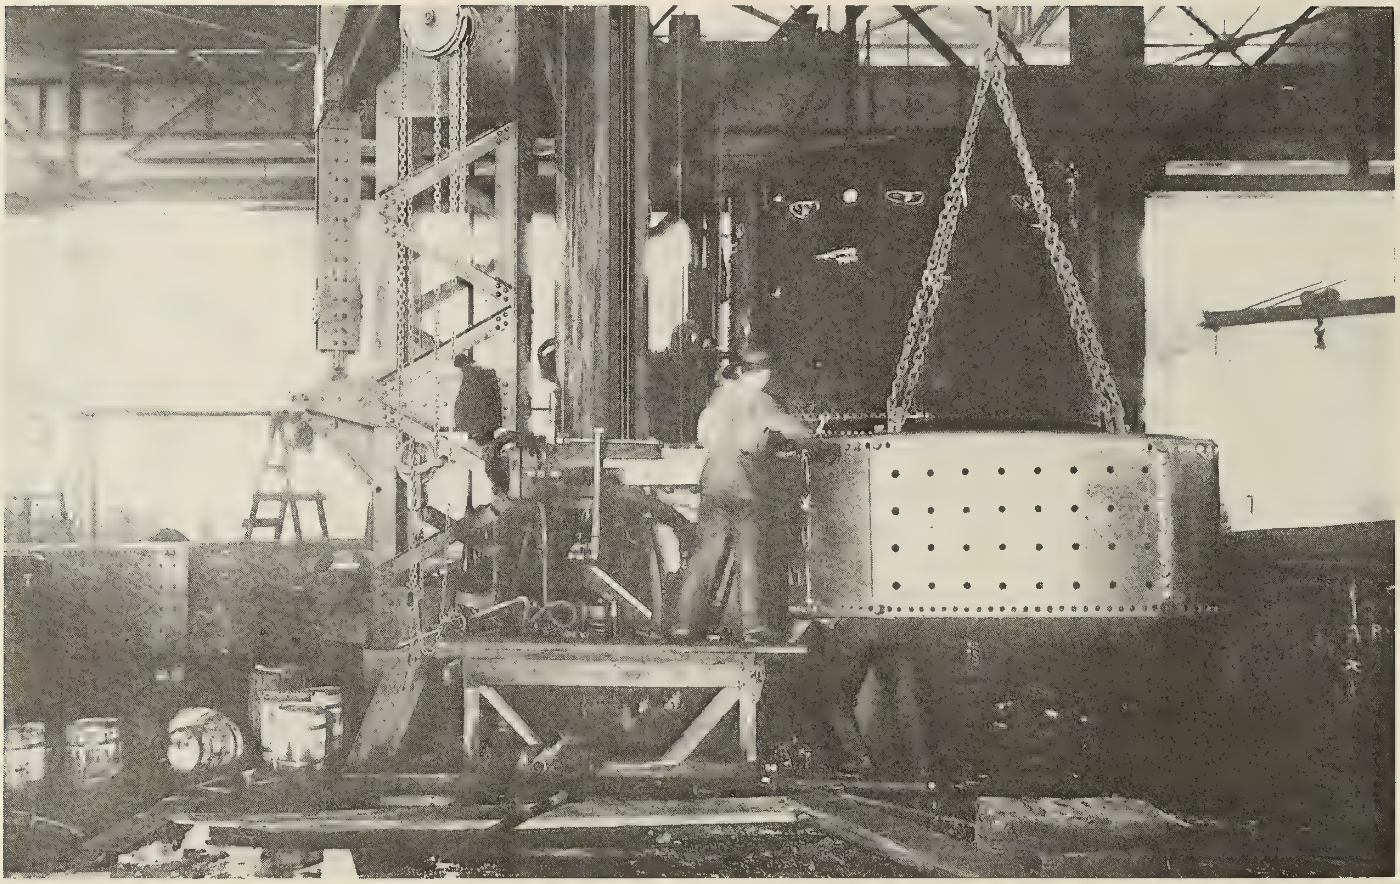

Fig. 9.—Riveting Combustion Chambers

Combustion Chambers

There are four separate combustion chambers in each boiler, each chamber being made up of 7/8-inch thick tube sheet and 11/16-inch thick back sheet and four wrapper plates. The top and side wrapper plates are 21/32-inch thick and the bottom plate 1 1/16-inches thick. All seams are single lap riveted with 1-inch countersunk rivets.

The backs of the combustion chambers have a 4-inch slope while the tops of the wing combustion chambers slope down toward the shell 5 inches from the center. All screw stays connecting the back sheets with the back head of the boiler are set in normal to the combustion chamber sheet. The screw stays are finished smooth between the plates to a diameter equal to the root of the threads.

Four furnaces of the Morison corrugated suspension type are fitted in each boiler and these have an inside diameter of 43½ inches. These furnaces have horse-collar connections to the combustion chamber with enlarged front ends to permit withdrawal.

Each boiler has six supporting saddles, three on each side, made of 1¾-inch plate 14 inches long. These saddles are secured to the shell with twelve 1⅝-inch rivets and a calking strip ¼-inch thick inserted between the shell and the saddles.

A perforated dry pipe 7 inches in diameter is fitted the full length of the shell with a cap on the end and securely fastened to the shell.

Large Amount of Welding Used

In order to insure a tight boiler at all times, under adverse operating conditions and the difficulty of maintaining boilers at sea, an unusual amount of electric arc welding has been done on all the boilers. The seams and stay nuts in the combustion chambers are welded up to a point 2 feet above the centerline of the furnace. The inside butt straps are beveled down on the ends to the thickness of the boiler head flanges and welded across the ends at that point and for a distance of 6 inches along the head flange and the same distance along the butt straps from the flange. Where the shell plates butt together they are beveled and welded for a distance of 12 inches from each end. The saddle lugs, which are fitted with a ¼-inch calking strip, as indicated before, are welded on the inside of the lugs to the shell.

All seams of the combustion chambers in contact with flame are welded inside and out to protect the edges of the plates and insure against any possible leaks. This welding is carried to a point 2 feet above the centerline of the furnaces. All screw stays up to a point 2 feet above the centerline of the furnaces are fitted with special round collar nuts which are welded after being screwed on the stays.

All welding is built up of several layers to the required amount, each layer being thoroughly wire brushed and hammered before the succeeding layer of welding material is added. The finished weld in all cases is then peaned with pneumatic hammers.

Fittings and Mountings

Six Diamond rear end soot blowers are fitted to each boiler; one in each wing combustion chamber and two in each inboard combustion chamber to enable all tubes being thoroughly swept by as near a direct jet of steam as possible.

All connections to the boiler heads and shell are fitted to nozzles of open hearth steel forgings which are riveted to the boiler. These nozzles are made of sufficient length to allow removal of valves without disturbing the lagging to get at the nuts and bolts. The main and auxiliary feed nozzles have necks extending through the head of the boiler and are fitted with a flange securely screwed on from the inside of the boiler. The zincs are supported by hooks on straps suspended down between the nests of tubes from the main stays. Thirty-six zinc slabs 12 inches by 6 inches by ½ inch are fitted.

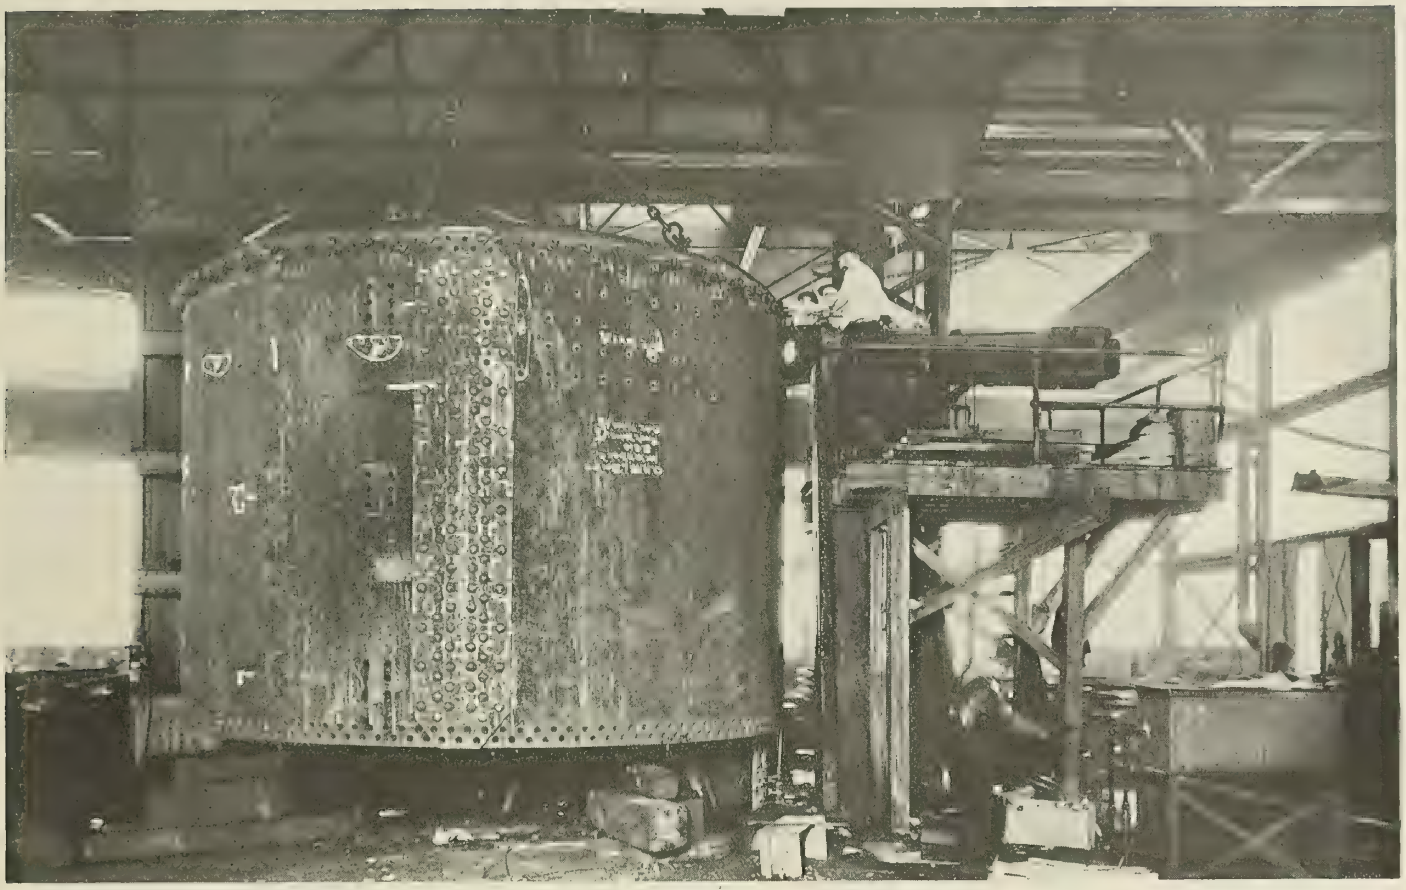

Fig. 10.—Fitting Up Head in Marine Boiler Shell

General Details of Boilers

Diameter of boilers (inside)	17 feet 6 inches
Length (over bottom heads)	13 feet 0 inches
Thickness of shell	2 inches
Number of furnaces	4
Inside diameter of furnaces	43½ inches
Number of plain tubes	462
Number of stay tubes	144
Outside diameter of tubes	2½ inches
Distance between tube sheets	8 feet 6 1/32 inches
Heating surface of tubes	3,370 square feet
Heating surface of furnaces	425 square feet
Heating surface of combustion chambers	465 square feet
Total heating surface	4,260 square feet
Net area through tubes	15.4
Steam pressure	225 pounds
Steam space	0.29
Equivalent grate area with 5-foot 6-inch grate	79.75
Heating surface ÷ grate area	53.4
Weight of boiler, dry	80 tons

The main steam connection is seven inches in diameter and is fitted with a wrought iron slotted dry pipe. A 1¼-inch Weir hydrokineter is fitted on the shell between inboard and wing furnaces for circulating water when starting to get up steam. A scum pan and salinometer cock are fitted to head of boiler. There are two water columns and three try cocks fitted to the head of the boiler.

Methods of Manufacture

All work of manufacture from the flat plates to testing has been done in the boiler shop of the Federal Shipbuilding Company which is one of the best equipped marine boiler shops in the country. On account of the great size and weight of the boilers special and extra equipment was made up for handling the work through the shop.

The butt straps were formed to shape under a 200-ton hydraulic press. The 1⅞-inch rivets in the butt straps were driven by a 200-ton hydraulic riveter. Rivets in the circumferential seam of the back head were driven by a 150-ton hydraulic bull, while the rivets in the straight seams of the heads and the combustion chamber seams were driven by a 75-ton bull. In the circumferential seam of the front head the rivets were hand driven with pneumatic riveting hammers. Special riveters of 80 tons pressure were used for the seam at the furnace mouth which is riveted the complete circumference of the furnace.

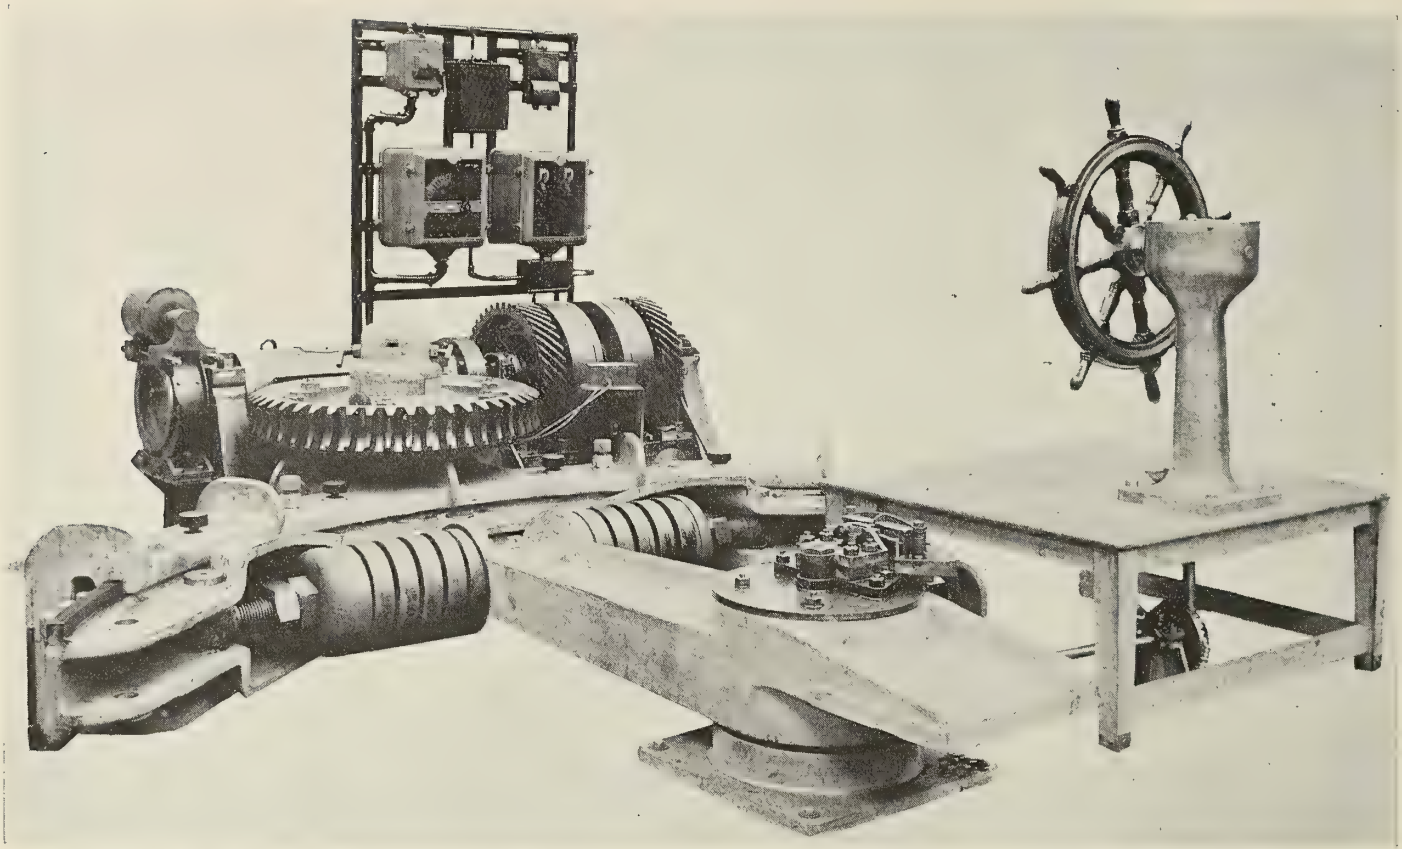
Because of the extreme thickness of shell plates, it was necessary to start the curvature by hydraulic press for a short distance, so that the plates could be entered in the rolls. The outer edge of the longitudinal joint had to be finished by hydraulic press to fair up properly when assembled. The curvature of the butt straps was also imparted by hydraulic press.

All plates were taken apart after fitting up and the surfaces cleaned and burrs removed with emery wheels before reassembling to insure clean metal to metal joints. In reassembling the work for riveting, dowel pins were used to insure perfect alinement of holes.

These boilers in general represent the last word in Scotch marine boiler design and construction and their service records will serve to uphold the reputation for reliability under adverse conditions that this type boiler has gained in its years of powering the merchant ships of the world.

Simplified Type Direct Rudder Head Steering Gear

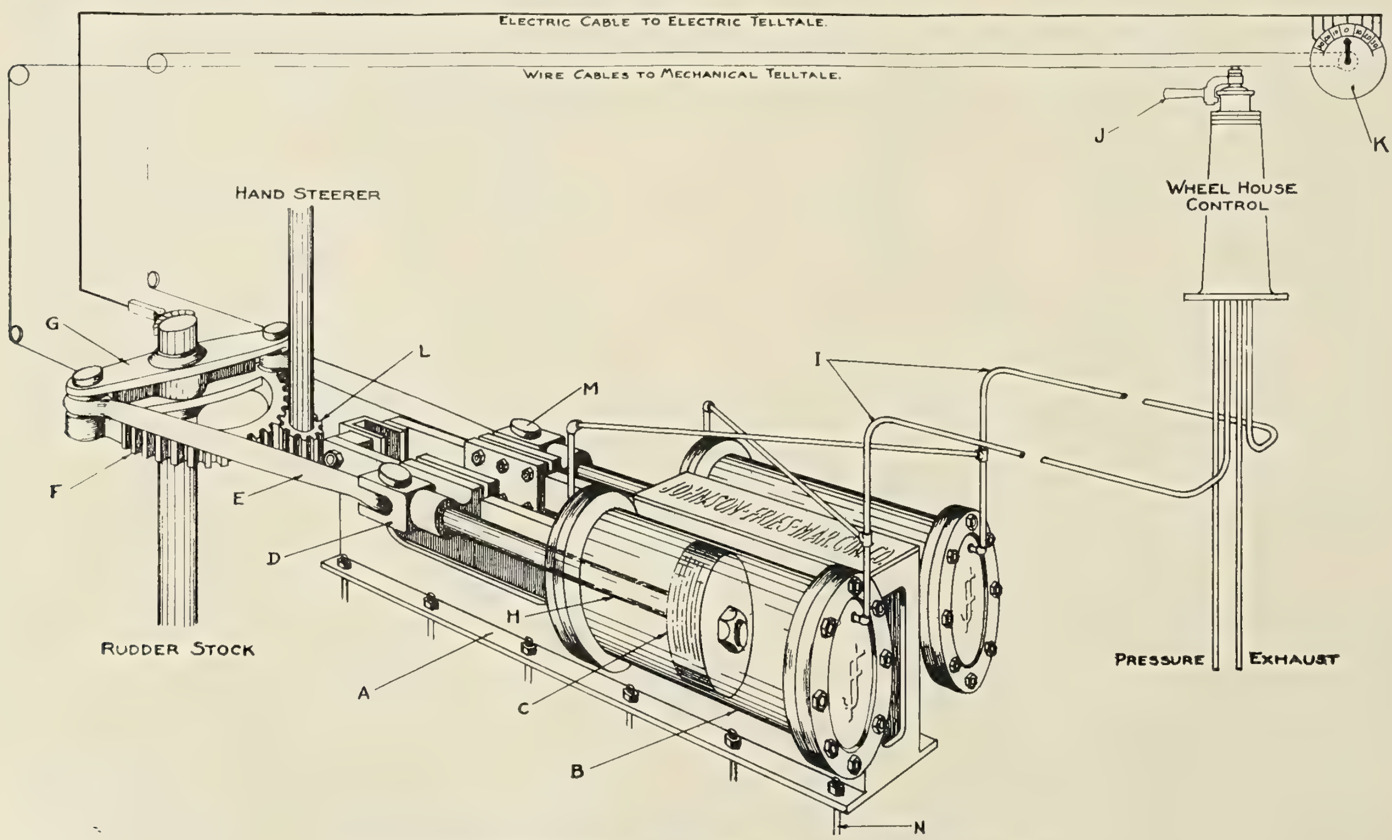
Working from the original barrel steering gear driven by a steam engine, through various stages of steam driven screw gears, the Bow, McLachlan & Company, Ltd., London, England, has developed an electrically operated direct rudder head gear which can be controlled by any of the customary methods at the various parts



Electrically Operated Direct Rudder Head Gear Attached to "Guided Segment" Type Steering Installation

of a vessel from which it is desirable to operate the ship. The motor actuating the gears runs continuously and drives two electro-magnetic clutches which run loose on the driving shaft. These clutches run in opposite directions, thus controlling the forward and reversing action of the shaft. The shaft may be arranged to operate a number of different steering installations.

In the accompanying illustration, the shaft is attached to the "guided segment" gear. In this case, a worm is connected to the end of the shaft which meshes with a horizon-



Diagrammatic Sketch of Johnson-Fries Pneumatic Steering Gear

tally mounted worm wheel carried on a spindle to which a toothed pinion is fixed. The latter meshes with a toothed segment connected through spiral springs to the tiller. Movement of the worm wheel shaft in one direction or the other turns the rudder to port or starboard as required.

Mounted on the rudder head is a new type of hunting switch which is actuated by the steering wheel. Motion of the wheel in one direction or the other completes the electric circuit to one or the other of the clutches and moves the rudder through the gearing described. When the rudder has moved to the angle corresponding to the angle of rotation of the steering wheel the hunting switch breaks the circuit to the acting clutch which releases the worm wheel shaft and stops further motion until the steering wheel is moved again.

To prevent overloading of the motor the clutches are arranged to slip at any pre-determined load without damage to themselves or resulting discrepancy between the rudder angle and position of the steering wheel corresponding to that angle.

Resistance of Ships to Propulsion

Methods of Estimating Power from Model Tests —Corrections in Passing from Model to Ship

By A. J. C. Robertson*

THE necessity for accurately calculating the power to propel a ship is so apparent that many attempts have been made to enunciate formulæ which will provide the information desired. We are all familiar with the well-known Admiralty formulæ,

$$\text{I. H. P.} = \frac{\Delta^{2/3}\, V^3}{\text{Constant}_1} \text{ or I. H. P.} = \frac{V^3\, M}{\text{Constant}_2}$$

where $\triangle$ is displacement in tons, V speed in knots and M area of midsection in square feet. We are probably also aware that the so-called constants vary enormously with size proportions and speed of the ship and, if the constant has to be guessed, we may as well guess the power at once.

A modification of the first formula recommended by A. E. Stevens,

$$\text{I. H. P.} = \frac{\Delta\, V^3}{\text{Constant}\sqrt{L}}$$

claims to give better results than the Admiralty formulæ but this constant varies through a wide range also with size of ship, draft ratio and speed ratio.

A very clever analysis of resistance was made by Professor Hovgaard in 1908 (Transactions of the Institution of Naval Architects) in which many provisional formulæ were worked out and curves plotted upon actual resistance curves, thus showing the measure of accuracy attained, but, though the resulting formula included wetted surface, coefficient of fineness, length, breadth, depth and speed, the "constants" were still found to vary considerably and in accordance with unknown laws.

This, however, is not surprising, for in the nature of things no formula of constant form can possibly take care of the infinite variations which can be made in the dimensions, proportions and form of a ship's hull. Even if all the dimensions are absolutely fixed, no two naval architects could possibly produce an identical set of lines.

Two such independent designs might and probably would have identical resistances at one speed, but the architects themselves could not say at what speed that would occur and the similarity would certainly not extend through any great range of speeds.

The major resistances which absorb the power used in the propulsion of a ship are here tabulated:

(a) Frictional resistance
(b) Wave making
(c) Eddy making
(d) Windage and rudder
(e) Restricted channel
(f) Wake deduction
(g) Propeller efficiency losses
(h) Shaft friction

*Naval architect, Munson Steamship Line, New York.

And if power is measured inside the engine by indicator cards or similar methods, the initial friction losses of the engine must be added to this list.

Froude, many years ago, was able to enunciate the laws of comparison which have made it possible to estimate the effect of size on the resistance of a vessel. This law, also called the law of mechanical similitude as applied to ships, requires that for ships that are exactly similar except in size, as expressed in terms of a single dimension, L:

(a) corresponding speeds are speed proportional to $\sqrt{L}$.
(b) corresponding displacements are proportional to L^3.
(c) corresponding resistances are proportional to L^3.
(d) corresponding powers are proportional to $L^{3.5}$.

This law at once made it possible to look for a solution of the problem of propulsion by the testing of small models under conditions which could be maintained the same at all times, or at least where the changes were so small and so carefully measured that proper corrections could be made.

A large experimental tank was constructed for this purpose at Torquay in England many years ago, and at this tank the foundations of the science of ship resistance were well laid by Mr. Froude.

Application of Model Experiments

It was early demonstrated that the friction of the water on the skin of a ship did not strictly follow the law of mechanical similitude owing to the layer in contact with the ship acquiring a velocity in the same direction as the ship, thus making a difference between the apparent and the real speed of the ship through the water, and this change in velocity was found to be a direct function of the length of the vessel. This skin resistance could be expressed thus:

$$R_f = SfV^n$$

where S is the wetted surface and V the speed, f and n being constants for a fixed length, and could be tabulated for various lengths of ship. With this allowance for frictional resistance taken into account it has been found possible to calculate from model experiments items (a), (b) and (c).

The resistance and speed of the accurately cut model ship are electrically recorded for a large number of speeds, a run of the model being made at each speed. From this total resistance (usually measured in pounds) the calculated resistance due to the surface friction is subtracted, the remainder, usually designated as the residuary resistance, is multiplied by suitable factors for the required size of ship and to the result the calculated frictional resistance of the ship is added, giving the total resistance, usually expressed in effective horsepower.

That is the method in use at both the Washington and Ann Arbor model tanks in this country, but another method

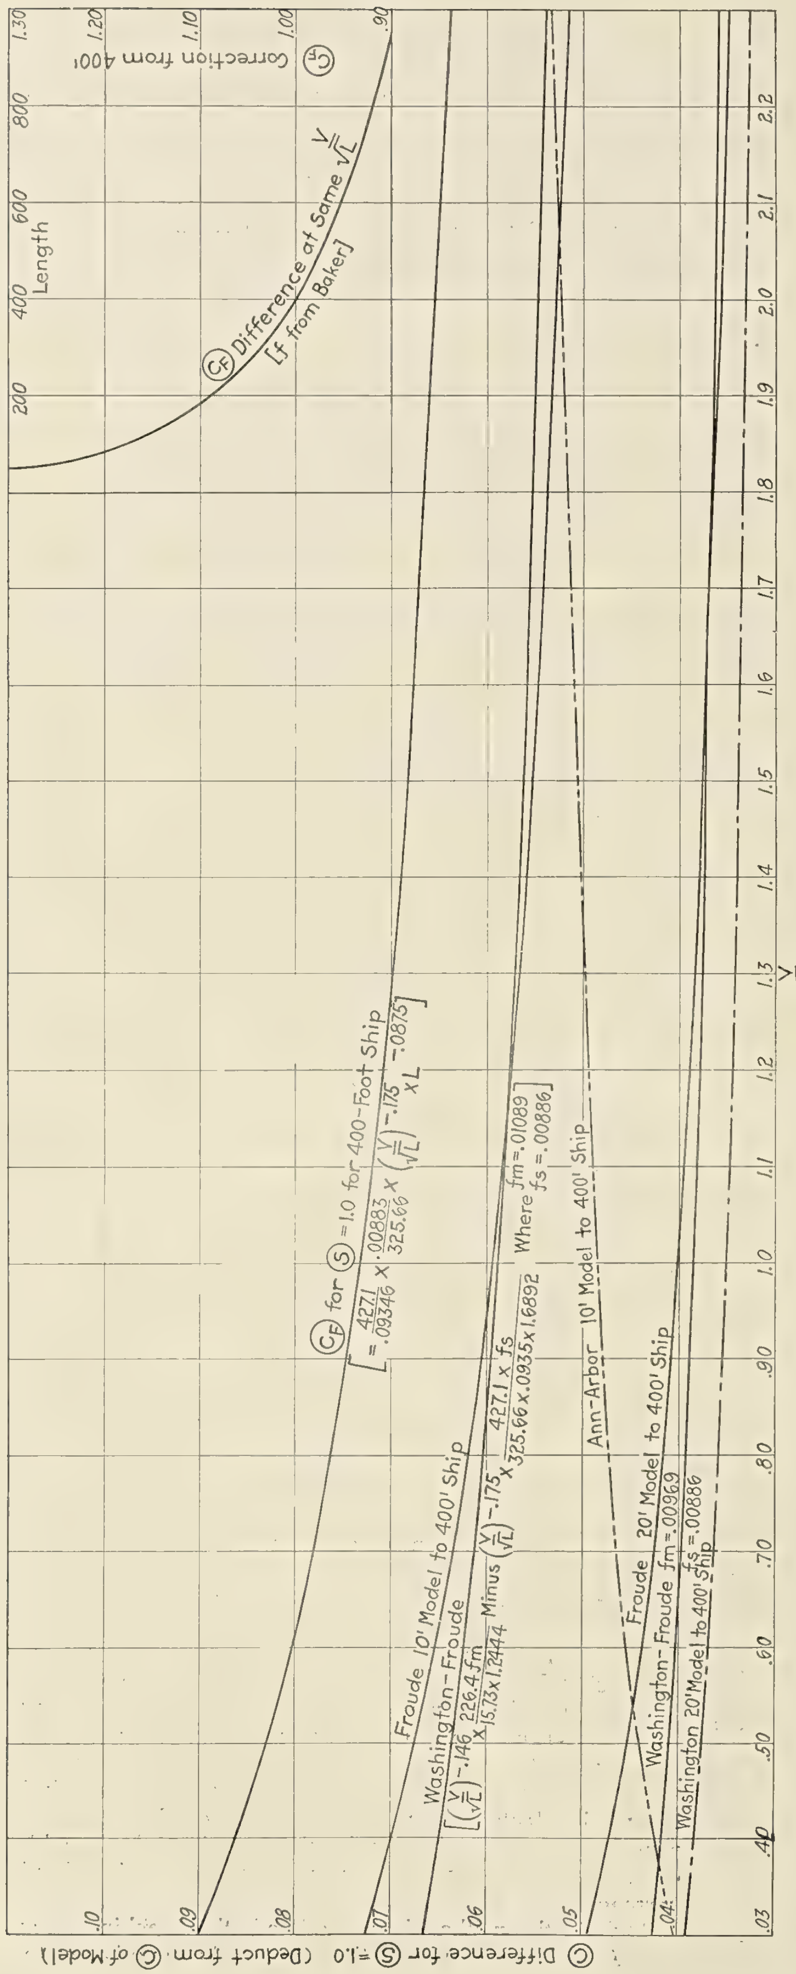


Diagram Showing (1) the Value of (C_f) at (S) = 1.0 for a 400-Foot Ship and (2) the Deduction from (C_f) of Ship with (S) = 1.0 as Calculated by Using the Coefficients of Various Authorities for 10-Foot and 20-Foot Models and 400-Foot Ship

is possible. This is to calculate the horsepower of the ship directly from the resistance of the model and then deduct a certain amount due to the lesser resistance per square foot of surface for the large vessel as compared with the model. Either method will of course give accurate results, but the latter method has some advantages, in that it proceeds by differences, thereby preventing large errors and it can be carried out in such a way as to give a unit of resistance equally applicable to any size of ship with a unit correction value for variations in size.

This method, originated also by Froude, designates the unit of resistance

$$(C) = \frac{\text{E. H. P.} \times 427.1}{V^3 \Delta^{2/3}}$$

and the (C) correction in passing from the model to a standard size of ship (for convenience 400 feet is probably the simplest) is in the form of a small deduction from the (C) value of the model.

For vessels other than 400 feet long the (C) correction is very small and is a deduction for larger ships and an addition for smaller ones.

This method of expressing the ship resistance by (C) value is now practically universal in Europe, and when once adopted is sure to displace other methods.

The reasons for this are that (C) is very sensible to variations of resistance, it fluctuates less than most constants and is easily utilized for speed estimates. Moreover (C) values are now available for a very large number of ship models, tested through a wide range of speeds.

Calculations for the (C) Values

A more detailed examination of Froude's "constant" system of notation and the calculations for the (C) values will therefore be interesting, especially as the calculations involved in obtaining (C) from model experiments have been omitted from the usual text books.

Δ = Displacement in tons, salt water at 35 cubic feet per ton.
δ = Displacement in pounds, fresh water at density 1.0 : 1.026 salt water.
V = Speed in knots of 101.33 feet per minute.
R = Resistance in pounds.
L = Length on waterline in feet.
W = Wetted surface in square feet.
U = Length of side of cube having contents equal to displacement in cubic feet.

Then $U = \Delta^{1/3}$

$$K = \text{Speed of wave of length } \frac{U}{2} = \frac{V}{\Delta^{1/6}}\sqrt{\frac{4\pi}{g}}$$

with speed V in feet, seconds and g., the accelerating force of gravity, in feet per second.

Also $$\frac{C}{1{,}000} = \frac{R}{\Delta K^2}$$

and assuming that the specific gravity of sea water is 1.026—64 pounds per cubic

EXTENSION OF MODEL TESTS TO SHIP

Design No. 2033

Test No. Ann Arbor 2033-B. Dated Aug., 1920. Name ....

ITEM	MODEL		SHIP	
Displ. Length........	10.0	Ft.	534.0	Ft.

foot, then the various constants for ship in salt water and model in fresh water will be as follows:

$$\text{Length Constant} \quad (M) = \frac{L}{\Delta^{1/3}} \times 0.3057 = \frac{L}{\delta^{1/3}} \times 3.966$$

$$\text{Skin Constant} \quad (S) = \frac{W}{\Delta^{2/3}} \times 0.09346 = \frac{W}{\delta^{2/3}} \times 15.73$$

$$\text{Speed Constant} \quad (K) = \frac{V}{\Delta^{1/6}} \times 0.5834 = \frac{V}{\delta^{1/6}} \times 2.047$$

$$\text{Resistance Constant } (C) = \frac{1.3115\ R}{\Delta^{2/3}\ V^2} = \frac{226.4\ R}{\delta^{2/3}\ V^2}$$

$$= \frac{101.33 V \times R}{33{,}000} \times \frac{427.1}{\Delta^{2/3}\ V^3}$$

$$= \frac{\text{E.H.P.} \times 427.1}{\Delta^{2/3}\ V^3}$$

$$\left[\frac{226.4\ R}{\delta^{2/3}\ V^2} = \frac{1.3115\ R}{\Delta^{2/3}\ V^2} \times 1.026 \times \left(\frac{2240}{1.026}\right)^{2/3} \right]$$

This (C) coefficient follows the laws of comparison and would therefore be strictly constant for any size of ship were it not for the fact that the frictional horsepower does not follow these laws.

The frictional resistance varies at something less than the square of the speed, and the coefficient of friction is higher for a short vessel than for a long one. As a consequence, the (C) calculated from the model tests will be greater than for the ship.

Unfortunately doctors differ as to the exact amount of the skin resistances, Froude taking a frictional coefficient for the 20-foot model of 0.01031 and for the 400-foot ship 0.00886 with a speed variation for both model and ship of

$V^{1.825}$ (i. e., R for wetted surface = S $\times V^{1.825} \times$ .00886).

At Washington the coefficient of friction for the 20-foot model is 0.00969 and for the 400-foot ship it is 0.00910, and the resistance is assumed to vary in the model as $V^{1.854}$ and for the ship as $V^{1.83}$.

The Washington constants for the ship are taken from the works of Tideman who, however, drew all his information from the original experiments of Froude.

The constants for the model in use at Washington were, however, obtained by careful tests at the Washington tank with facilities probably considerably better than Froude originally had at his disposal. It is my opinion, therefore, that by using the Washington model coefficients in conjunction with Froude's ship coefficients the closest possible approximation to the E. H. P. of the ship can be obtained. This will give C values very slightly higher than by Froude's coefficients.

The correction applied to (C) in passing from the model to the ship will of course be the difference in C value for skin friction as calculated by the coefficients for the model and for the ship.

They are therefore a function of the wetted surface and may be most conveniently tabulated for (S) = 1.0.

A diagram is given herewith showing (1) the value of (C_f) at (S) = 1.0 for a 400-foot ship and (2) the deduction from (C_f) of model for (C_f) of ship with (S) = 1.0 as calculated by using the coefficients of the various authorities for 10-foot and 20-foot models and 400-foot ship. On the same diagram, as an inset, is shown the percentage change in (C_f) value for other lengths of ships.

For greater convenience these values are also tabulated for the usual speed ratios.

(C_f) Differences Passing from Model to 400-foot Ship for (S) = 1.0

$\frac{V}{\sqrt{L}}$	20-Foot Model			10-Foot Model		
	Froude	Washington	Wash.-Froude	Froude	Ann Arbor	Wash.-Froude

0.50	.0454	.0375	.0410	.0670	.0442	.0635
0.60	.0440	.0369	.0403	.0650	.0453	.0623
0.70	.0428	.0364	.0398	.0633	.0464	.0612
0.80	.0418	.0359	.0393	.0618	.0471	.0603
0.90	.0410	.0355	.0389	.0605	.0478	.0596
1.00	.0402	.0351	.0385	.0594	.0484	.0589
1.10	.0395	.0348	.0382	.0584	.0489	.0583
1.20	.0389	.0345	.0379	.0575	.0494	.0577
1.30	.0384	.0343	.0376	.0567	.0498	.0572

The work of extension from model to ship may be arranged as shown herewith, the table being self-explanatory in great measure. Column 6 contains the (C) differences as above for (S) = 1.0 and these differences multiplied by (S) value, 6.49, and by a small temperature correction factor 1.017 are tabulated in column 7 and are subtracted from (C) value for model given in column 5 to give (C) for 400-foot ship in column 8. Column 9 is left blank as it is convenient for various purposes such as for tabulating (C) value with Froude or Washington correction.

The (C) correction in passing from one ship to another is of course of the same nature as that for passing from model to ship, and may be calculated from the diagram, but it is so nearly constant for all speeds that it can conveniently be tabulated for a speed ratio of say 0.80 and a value of (S) of say 6.50, thus:

Length	(C) Correction	Length	(C) Correction
100 feet	+ .0877	500 feet	— .0132
200 feet	+ .0406	600 feet	— .0233
300 feet	+ .0173	700 feet	— .0313
		800 feet	— .0398

The data given in the example herewith is for an exceptionally good model, and it is very unusual to have the (C) values below about 0.65. (S) values usually range between 6.0 and 7.0 and depend on draft ratio and (M) value to a considerable extent.

The draft ratio δ used expresses the ratio of depth of the rectangle of ship's breadth and mid area to that breadth.

What the Shipping Bill Is and Does

(*Continued from page* 606)

traveling at public expense, and all government supplies must be carried in American vessels wherever practicable.

Further paragraphs of the new bill define in some regards the relation of railroads and steamships. The provision of section 28 of the Merchant Marine Act of 1920, not yet enforced, requiring that goods for export and import enjoying preferential rates on American railroads, shall be conveyed in American ships, is clarified in some particulars.

National aid under contract will endure at least 10 years, as this is stipulated as the contract period.

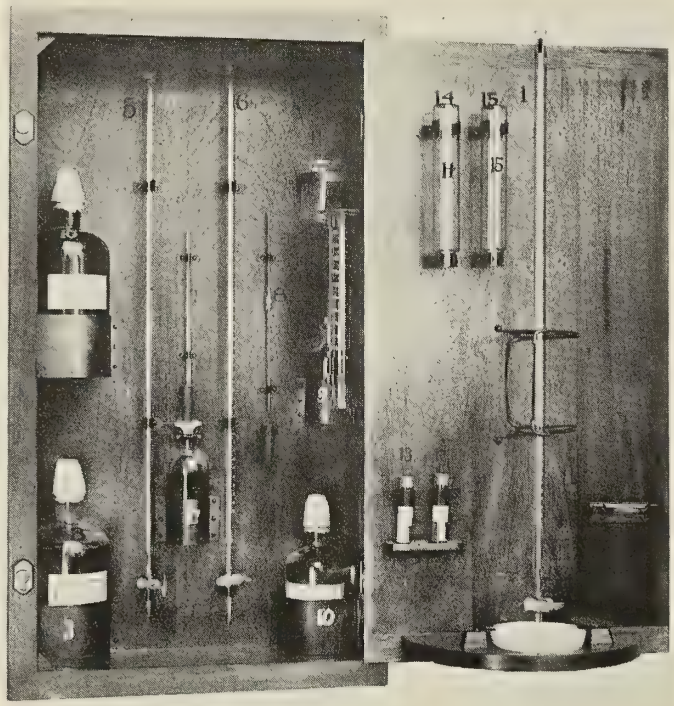
Cost of New Shipping Bill

But what will the new shipping bill cost year by year? Not more than $15,000,000 in total compensation the first year, is the estimate of experts of the Shipping Board, and not more than $40,000,000 a year at its maximum some years hence, when a merchant marine of 7,500,000 tons gross register, capable of carrying from 50 to 60 percent of our own exports and imports, has been properly developed in the foreign trade.

At present the Shipping Board reports a loss of nearly $50,000,000 a year on its 450 ships in operation. Considering both indirect and direct aids, including the deductions from income taxes, it is a just estimate that the cost of the bill at its highest figure will be kept well within $50,000,000. Moreover, it should be borne in mind that the upbuilding of a great merchant marine will produce increased income taxes from shipowners, employment for labor, and an expansion of our export trade, thus creating additional sources of public revenue. Still further, it is an axiom that private control and operation of our merchant ships are far more economical than government ownership and operation—even when the government experiment is being tried under the happiest of auspices.

Set for Testing the Alkalinity of Boiler Feed Water

A PRECISION feed water testing set, for which the makers, the Precision Water Treating Company, Brooklyn, N. Y., claim an accuracy in determining alkalinity to 1/10 of one percent and salt contained to 1/10 of one grain per gallon, has recently been made available to stationary power plant and marine boiler uses. In marine



Precision Feed Water Testing Set

work especially it is vitally important that the salt content of the feed water be under constant check, so that leaks in the condensers, pump lines, distillers and boilers may be determined at their inception.

It is also desirable to maintain water at the proper degree of alkalinity to prevent scaling and corrosion with resultant savings in fuel and lengthened periods of service between cleanings. The precision water testing apparatus is designed to perform convenient and accurate determinations in a quantitative manner. Demonstrations are made at the office of S. Aitken, agent of the company, Room F, 11 Broadway, New York.

International Shipping Conference Committee Reports

At the International Shipping Conference held in London last November committees were appointed to investigate exhaustively many of the questions discussed at the conference. As a result the following committee reports have been submitted to the president of the conference covering the subjects of Life-Saving Appliances, Wireless Telegraphy, Load Lines and the Subdivision of Passenger Liners.

Life-Saving Appliances

THE Committee was appointed under a resolution of the International Shipping Conference, passed in November, 1921, which defined the principles upon which any further consideration of that part of the problem of Safety of Life at Sea which more particularly relates to Life-Saving Appliances should be based. The first meeting was held in London on May 22; it was agreed that the Convention of London, 1914, should be taken as the basis of discussion, bearing in mind the principles underlying the report of the Merchant Shipping Advisory Committee, 1912. In the committee's opinion, a cardinal error was committed by the Government's signatory to this Convention in departing from the principles contained in this report and in substituting therefor other principles which failed in any degree commensurate with the anticipation of such Governments to save life after marine casualties.

To the main recommendations of that committee the International Shipping Conference adhered in their resolution of November, 1921, and with the disaster of the *Egypt* fresh in the committee's minds, it urges them upon our Governments.

Among the resolutions passed were: That the attention of the Board of Trade be drawn to the *Egypt* disaster and to the fact that the opinions expressed at the International Conference are thereby confirmed as follows:

(i) The Board of Trade referred, after the loss of the *Titanic*, the whole question of boats and life-saving appliances to the Merchant Shipping Advisory Committee.
(ii) That committee reported in favor of certain principles being adopted by the Board of Trade.
(iii) Had these recommendations been fully acted upon, subsequent experience under conditions both of war and of peace shows that loss of life at sea might have been diminished.
(iv) Nevertheless, the Government's signatory to the Convention of London proceeded upon other principles which shipowners then feared and which have proved to be detrimental to safety of life at sea.

That all Governments be accordingly invited to take immediate steps to revise the Convention in accordance with the Report of the Merchant Shipping Advisory Committee, 1912, as amplified by the recommendations of the committees of the International Shipping Conference concerned with safety of life at sea.

Wireless Telegraphy

(*a*) Amendments to the Convention of London

After consideration of the Articles of the Convention of London relating to wireless telegraphy, and having taken into account memoranda submitted on behalf of the German and Italian delegates, the committee recommends the following amendments:

Article 32.—It was agreed—

1. That in order to allow for partial as well as total exemption of coasting and short sea trade vessels, the opening sentence of the second paragraph of Article 32 should be amended.

2. That paragraph 2 (sub-section 1) should be amended by the substitution of the words "200 sea miles from the nearest coast" for the words "150 sea miles from the nearest coast."

Article 34.—It was agreed that the following words be added to Article 34 after the words "High Contracting parties" in the last paragraph but two:

"An automatic calling apparatus shall be deemed efficient if it can take the distress signal and the safety signal and reaches 80 percent efficiency in an open sea test under service conditions.

"The shipowner may employ a navigating officer or other member of the crew in lieu of a wireless operator, provided such person has qualified for a special certificate of competence to receive and transmit wireless signals in connection with safety of life at sea. Such person shall not be required to keep any specified watch on the wireless instruments, provided that he is always available in the case of emergency and that the continuous watch when required by the Convention is kept by automatic or human agency."

Article 35.—It was agreed that the first paragraph of this Article should be altered to read as follows:

"The Radio Telegraphic Installation required by Article 31 above shall be capable of transmitting clearly perceptible signals for the purpose of safety of life at sea from ship to ship over a range of at least 100 sea miles by day under normal conditions and circumstances."

(*b*) General Recommendations

1. *Basis of obligation to carry Wireless.*—We have considered this question, and find that the basis provided in Article 31 of the Convention is logical and satisfactory; this number should refer to those actually on board, in accordance with the Convention, and not to the number of those for whom the ship may be certificated.

2. In the event of the Government of any State signatory to the Convention exercising the powers of Article 32 in the sense of differentiating between passenger and cargo vessels under sub-section 1, we recommend that the obligation to carry wireless shall not in any event be placed upon passenger vessels unless they have 100 passengers on board.

3. *Automatic device.*—The most immediate need in connection with the use of wireless is the development and approval of an automatic device. Some doubt, however, having been raised on the committee as to whether the apparatus in its present form was sufficiently developed to allow of its early or immediate adoption, they invited technical representatives of the different wireless companies in Great Britain to give evidence on this point. Evidence was accordingly received from Commander A. J. Slee, representing the Marconi Company, and from Mr. R. Ferguson, on behalf of the Radio Communication Company. Mr. H. Machin, manager of Siemens Bros., Limited, was unable to attend, but he has since told the committee that, while he believes it to be impossible for an automatic device to record the existing S.O.S. signal, he hopes that with an altered distress signal an effective automatic device could be put on the market.

The representatives of the Marconi and Radio Communication Companies stated that, if the alarm call were altered, there would be no difficulty in providing an apparatus to take such altered signal with an even greater percentage of efficiency than that of an instrument described.

It is not reasonable, however, to expect wireless companies to submit for trial or embark upon the manufacture of these instruments until the conditions of their trial and acceptance by the authorities have been definitely laid down.

It was accordingly resolved:

(a) That the Governments of the various maritime States be urged again to apply themselves to the immediate approval of an automatic device to receive emergency calls.

(b) That with this object the purpose which such instrument is required to meet should be restricted to the taking of emergency calls under ordinary service conditions at sea; and

(c) That existing devices should at once be re-tested under the same service conditions with the object, if possible, of approving immediately a device which will respond under normal service conditions at sea to the existing distress call, *but that if this is not possible, active steps should be forthwith taken to agree internationally on a new distress call which is capable of being so taken.*

4. *Wireless as a Navigational Duty.*—The committee recommends that apprentices should be trained in wireless, as in navigation, and that existing masters and navigating officers should be encouraged to take a wireless course to secure their certificates, and that each Government should institute a special examination and certificate of competence to operate the instrument for ship's service, including safety of life at sea.

5. *Directional Wireless.*—The committee attaches the greatest importance to the development of this branch of wireless telegraphy, but thinks it necessary to point out that a navigational instrument which will add to the safety and decrease the cost of running ships is of such commercial importance, that shipowners may without risk be left to choose their own time and method for its adoption, and that the fewer Government regulations that are applied to it the more satisfactory and the swifter will be its development. In the same way they desire to encourage shipowners to make use of wireless for the receipt of time and weather signals, but are strongly of opinion that this is a point upon which Government interference would be quite inappropriate.

Life-Saving Appliances

It was reported that the British Government had again remitted to the Merchant Shipping Advisory Committee of the Board of Trade the question of life-saving appliances, with an instruction to revise the appropriate sections of the Convention of London in accordance with more recent experience. On this subject, the Committee states: "We have already stated our opinion that the principles enunciated by this Committee, which were reached in 1912, were sound, and that every successive failure of the regulations adopted by the various Governments in contradiction of their report has only served to confirm the wisdom of their first decisions. We here desire to express the hope that the Merchant Shipping Advisory Committee will reaffirm the principles then established, as amplified in the terms of the resolution passed by the International Shipping Conference, and which it has been our task further to interpret. In particular, we endorse the principle that boats in excess of those which can readily be launched are an encumbrance and a danger, and that in a disaster many lives may be saved by light and handy buoyant apparatus.

"Since the *Titanic* a series of disasters at sea proves the danger of encumbering the decks with boats which cannot be launched, and the need for buoyant apparatus which can easily be handled or will float off when the ship sinks and give support till rescue comes.

"These general principles have been translated into specific recommendations for the amendment of the Convention by our technical sub-committee in their report, which we attach, and unanimously commend to the Conference.

"We desire to re-affirm the Resolution of the International Conference:

"'That inasmuch as International Conventions become valueless, if any contracting Government applies different rules, whether less or more severe, to all ships visiting her ports, the attention of Governments signatory to the Convention should at once be called to instances in which the international accord of the Convention has been disturbed by particular regulations in order that the disturbance may be removed.'"

The reports are signed by the following: A. G. Anderson (chairman), Great Britain; Chas. A. Bartlett, Great Britain; Ing. E. Benvenuti, Italy; David Boyd, Great Britain; Jas. Carnegie, Belgium; E. Falcoz, France; H. Garde, Denmark; John R. Hobhouse, Great Britain; O. A. Nordborg, Sweden; W. H. J. Oderwald, Holland; N. Ohtani, Japan; I. Hysing Olsen, Norway; L. Peskett, Great Britain; Alejandro de la Sota, Spain; Warnholtz, Germany; J. Rypperda Wierdsma, Holland; P. Maurice Hill (secretary), Great Britain.

International Load Line

The International Shipping Conference, held in London on November 23, 24 and 25, 1921, passed the following resolution:

"That this conference, representative of the shipping industry in every part of the world, is of the opinion that the time is opportune for the introduction of International Load Line Regulations.

"That with this object a committee be appointed to investigate and determine the form of regulations capable of International acceptance.

"That such committee consist of one member appointed by representatives of each country, and that the registration bureaus and the classification societies be invited each to appoint a representative on the committee, and that the committee appoint a secretary."

In accordance with the terms of reference as shown above, the committee held its first meeting on May 22, 1922.

It was agreed that the Report No. 10, which had been submitted to the International Shipping Conference in November of last year, should be taken as the basis of discussion, together with the Memoranda received from other countries, namely: (1) Scandinavia, dated Copenhagen, April 25, 1922; (2) Germany, dated April 26, 1922; (3) Holland, dated April 24, 1922; (4) Holland, undated; (5) Japan, dated May 16, 1922.

In the course of general discussion, it was recognized that the question of allowance for freeboard for certain classes of superstructure was closely associated with the question of tonnage measurement, and that certain anomalies in the assignment of freeboard had arisen on account of the preferential treatment of spaces exempted from tonnage measurement. It was recognized, however, that this question of tonnage was affected by the action of Port Authorities and others, and it is necessary for a general agreement to be arrived at.

Enclosed Spaces

As regards the question of freeboard assignment, it was recognized that if a space was totally enclosed, it should have a full allowance for freeboard, and that otherwise the allowance for freeboard should be varied in respect of the means of closing adopted.

Discussion also took place on the basic tables of freeboard, and the general opinion was that the freeboard at present required for the usual type of vessels was satisfactory, and that, as regards small vessels of usual type, no increase of freeboard appeared necessary.

It was felt that the present freeboards of flush deck vessels required some increase, and it seemed to be generally agreed that all flush deck vessels should be provided with a forecastle or, alternatively, if this were not done, there should be a greater increase of freeboard. This increase of freeboard forward might perhaps be obtained by the adoption of suitable sheer.

Particular attention was directed to the standard of strength proposed by the load line committee, and it was observed that in the Japanese regulations on load line recently issued, the load line standard had been adopted with only slight modification. Opinion was divided on the question, some of

the delegates being in favor of the adoption of the proposed standard, others considering that the recognized authorities should set up suitable standards.

The conditions of assignment of freeboard, as proposed by the load line committee, were considered at some length. The committee was satisfied that the greater part of these conditions had already been adopted by the action of the classification societies, and that it would be preferable at the present time to confine their attention to the main points of the freeboard question rather than to detail the points involved in these clauses.

Wood Deck Cargoes

Reference was made to the determination of freeboard for vessels carrying wood deck cargoes, and attention was drawn to the recent report of the deck cargoes committee of the International Shipping Conference on this subject. It was observed that this report did not agree with the observations of the load line committee on this question, and that the rules already proposed in the report referred to provide for the assignment of freeboard for vessels carrying such cargoes by allowances based on the freeboard regulations for a steel steamer.

This committee, in common with the previous committees on subdivision and on deck cargoes, experienced difficulty in regard to variations of freeboard permitted for different seasons of the year and for different geographical regions. They confirmed the opinion already expressed by the other committees that it was very necessary that the Governments of maritime countries should take common action to define the summer and winter season, not only for the North Atlantic region, but also for other regions of the globe where similar treatment might be suitably and safely granted.

It is to be observed that when this question of regional variation is under discussion, special regard should be paid to certain waters, which might be regarded as inland seas, such, for example, as the Baltic, which is sometimes regarded as suitable for favored terms in respect of maritime legislation.

Not Retrospective

The committee was agreed that the application of those rules would only affect the freeboard of ships *to be* built, and that the proposals should not be made compulsory retrospective to vessels already in existence. They were further of opinion that these rules were framed for international ocean-going trade.

It was observed that the rules proposed by the load line committee did not make provision for the assignment of freeboards to vessels of exceptional types or forms, and it is presumed that some special schedule of requirements in regard to such vessels would need to be laid down at a future date.

The committee then proceeded to deal in detail with the report of the load line committee, and, in regard to the question of stability, were of opinion that it was only necessary to state that the assigning of a freeboard mark did not give any guarantee as regards the stability of a vessel. The clause that requires a master to exercise authority in this respect should, therefore, be deleted. There was, however, an opinion expressed that certain countries might find it desirable to retain this clause or to substitute for it any other that conformed with the law of the country.

The definition of freeboard and the methods of marking were generally agreed to.

The definitions of standard types of vessels and of the principal dimensions were generally concurred in, except that some opinion was expressed that it was desirable in all these technical regulations to have a uniform definition of length. The committee was of opinion that in vessels with cruiser sterns, the length should be taken to the center of the rudder stock, or to 96 percent of the total length overall, whichever was the greater, subject, however, to a reservation on the part of the Norske Veritas and the Technical Adviser for Denmark as to this altered reading.

The characteristics of standard vessels were next considered, and the ratio of length to freeboard depth and standard round of beam were agreed to, and the bases of the table for determination of freeboards (Article 8) were also concurred in.

The committee proceeded with the discussion of the correction to be made to the freeboards for departures from the standard, and were generally in agreement with the corrections necessary for the variation of length to depth ratio for sheer correction, and for round of beam correction. The question of immersion of the freeboard deck, as contained in Article 16 of the load line committee's report, met with the approval of the committee.

Standard Height of Superstructures

The question of the standard height of superstructure was discussed by the technical sub-committee, and it was agreed that:

The last clause of Article 7 (d) of the load line committee's report should be amended to read as follows:

(a) The standard height in feet of superstructures which are fitted abaft amidships is 3 feet when the length of the vessel does not exceed 100 feet and 5 feet when the length of vessel is 350 feet and above.
(b) The standard height in feet of superstructures which are fitted forward of amidships is 5 feet when the length of the vessel does not exceed 100 feet and 7 feet 6 inches when the length of the vessel is 350 feet and above.
(c) For intermediate lengths the standard height is to be obtained by interpolation.

This recommendation sets up a standard height for after superstructures, as well as for forward superstructures.

The sub-committee also considered the most important subject of the basic freeboard tables, as contained in the appendix to the load line committee's report. The committee was generally in agreement with those tables for flush deck vessels, but the representative of the Norske Veritas considered that the freeboard should be larger for such vessels.

Considerable discussion necessarily arose on Article 13 of the load line committee's report, dealing with the allowance to be granted for superstructures with various types of closing apparatus, and the committee was of opinion that the allowances, as contained in Table 2 of the load line committee's report, should be modified in accordance with the following recommendations:

In regard to the question of closing appliances, it was agreed that 100 percent allowance should be given to shelter deck vessels with a tonnage opening closed with closing appliances (storm boards full height), fitted at each end of the tonnage well. It was agreed that full allowance should be given for bridge houses which were closed by Class 1 appliances at the fore end, and either Class 1 or Class 2 appliances at the after end, in conjunction with open scuppers. In the case of a combined poop and bridge, it was agreed that the full allowance should only be given when the openings, if any, were closed with Class 1 appliances. Portable plates, whether secured by bolts through the bulkhead plating, or by hook bolts, should be included in Class 2 closing appliances, but that storm boards of half height should be regarded as non-existent.

Standard Sheer

The question of a standard sheer was investigated, and the recommendations of the load line committee were agreed to, subject to a reservation on the part of one of the Dutch representatives. The Norwegian and Swedish representatives also made a reservation in regard to the case of shelter deck vessels having a tonnage opening aft, and were of the opinion that in such cases the sheer should be measured relative to the shelter deck and not to the upper deck.

The committee had under consideration the modifications which could be made to the regulations for the assignment of freeboard for wood and composite vessels, and they recommend that:

(1) The length shall be measured in the same manner as for a steel vessel.
(2) The breadth shall be measured to the outside of the planking amidships instead of the outside of the frame amidships.
(3) The freeboard depth to be used with the Tables is the vertical distance amidships from the point where a continuation outwards of the upper surface of the freeboard deck intersects the outer surface of the shell or planking to the level of the top of the keel in steel and iron vessels, and to the lower edge of the rabbet of the keel in wood and composite vessels. When the form of the lower part of the midship section is of a hollow character, the depth is, however, to be measured to the point where the line of the flat of the bottom continued inwards cuts the side of the keel. When the rise of the floor exceeds 1½ inches per foot of a half breadth, the freeboard depth may be reduced by half the difference between the total rise of floor at the half breadth and the total rise at the standard rate of 1½ inches per foot. Two and a half inches per foot of half breadth is, however, to be the maximum rate of rise on which an allowance is to be made.

The committee was also of the opinion that this definition of depth might with advantage be substituted for the definition given in Article 6 (c) of the load line committee's report.

It was agreed that the computation of the freeboard of sailing vessels should be in accordance with the rules for steamers, such an addition being made as would bring the assignment into practical agreement with the present summer freeboards for such vessels. The summer and winter marks could be retained as at present.

Non-propelling barges should be treated on the same basis as that laid down for sailing vessels.

The committee was very much exercised with the definition of the term "steamer," as contained in Article 1 (a) of the load line committee's report. They were of the opinion that consideration should be given to the question of speed and power, and suggest that some minimum brake horsepower should be associated with the load displacement of the vessel. It was not possible at present to determine a satisfactory standard, but it is recommended that this subject be left over for further study.

The report was signed by the following: Belgium, Christian Sheid; Denmark, J. A. Koerbing; France, E. Patry; Germany, Warnholtz; Great Britain, Walter J. Chambers and H. B. Hooper; Holland, W. Royer; Italy, C. Camalich; Japan, W. Yokoyama; Norway, Halfdan Ditlev-Simonsen; Spain, Alejandro de la Sota (for Bilbao Shipowners' Association); Sweden, O. A. Nordborg; for Bureau Veritas, E. Patry; for Det Norske Veritas, J. Bruhn; for the British Corporation, Benson Taylor; for Lloyd's Register, W. S. Abell.

The Subdivision of Passenger Liners

The International Shipping Conference, held in London on November 23, 24 and 25, 1921, passed the following resolutions:

(1) That international uniformity in regulations for the subdivision of passenger vessels is necessary.
(2) That the International Code of Regulations contained in the Convention of London is incomplete, unsatisfactory and demands immediate revision.
(3) That any revision of the Convention must be such as to secure effective administration of the regulations by all the signatories, to the end that certificates of safety may have international validity.
(4) That any revision of the Convention must have regard, in conformity with Article 17, to the nature of the services in which the vessels are engaged and must be consonant with the economic conditions under which they are operated.
(5) That a committee of the Conference shall be appointed to consider and report in due course on the manner in which the Convention should be modified.

In accordance with the terms of reference contained in the last of these resolutions, the committee held its first meeting on May 8.

It was agreed that the Report 11a, which had been submitted to the International Shipping Conference in November of last year, together with the letter of December 14, 1921, and the memorandum dated April, 1922, should form the basis of discussion. (See Appendices.)

The Factorial System Preferred

On the relative merits of the graduated and factorial systems for regulating the spacing of bulkheads, it was agreed—

(a) That the factorial method should be adhered to, especially in view of the fact that such procedure would accord with the attitude already taken up by various Governments and would therefore facilitate final agreement.
(b) That below a certain length of vessel it was not economically possible to provide a one-compartment standard of subdivision throughout the length.
(c) That greater simplicity and directness of method for flooding calculation was desirable, and that a code or codes might advantageously be adopted from which floodable length curve, draft penalty, and index of permeability could be derived, provided that the codes used by different countries were guaranteed to give results differing by not more than 2 to 3 percent, and provided that shipowners had the option of employing a method involving the use of first principles in the calculations.
(d) That a criterion, based on mean permeability of all spaces, as suggested by the bulkheads committee was unacceptable.
(e) That provision in cargo carrying vessels must be made for a minimum length of hold, but as to the precise minimum there was some difference of opinion; the German delegation stating that the economic requirements of their mercantile marine did not call for a length of main hold as much as 80 feet.

At the conclusion of this general discussion the committee adjourned after appointing a technical sub-committee. This sub-committee held four sessions, and on May 12 presented its report to the plenary committee. At the same time a letter was received by the chairman from Mons. Nizery stating that the French delegates, who had attended all the meetings up to May 12, could no longer collaborate in the work of the committee.

Recommendations

The recommendations or findings adopted either absolutely or with reservations as recorded in this report fall into two parts.

I. Those adopted when representatives of all the delegations were present.

II. Those adopted when representatives of all the delegations, excepting only the French, were present.

They are:

Part I

(1) That in vessels below a certain length it is not possible, consistently with their economic use, to space the bulkheads so closely that the vessel will float with any one compartment open to the sea.

(2) That greater simplicity and directness of method for flooding calculations is desirable, and that a code or codes, including that recommended by the British bulkheads committee, without correction for form, might advantageously be employed from which floodable length curve, draft penalty and index of permeability could be derived, always provided that the codes used by different countries were guaranteed to give results differing by not more than 2 percent to 3 percent from an agreed standard, and provided that shipowners had the option of employing a method involving the use of first principles in the calculations.

(3) That the factorial method for regulating the spacing of bulkheads should be adhered to, especially in view of the fact that such procedure being in accord with the attitude already adopted by various Governments would facilitate final agreement.

(4) That a criterion of service based on the mean permeability of all spaces included in the gross tonnage as suggested by the bulkheads committee is unacceptable.

(5) That in vessels carrying mainly cargo with a nominal number of passengers, whether above or below the bulkhead deck, provision must be made for a hold of a minimum length, but opinion as to the precise minimum was not unanimous, the German delegation considering that 80 feet, the minimum suggested by the British delegates, was in excess of the requirements of their own trade.

(6) That the curve *B*, as given in Report IIa is acceptable as satisfying both safety and economic requirements. (This is subject to the reservations by the German and Japanese delegations.)

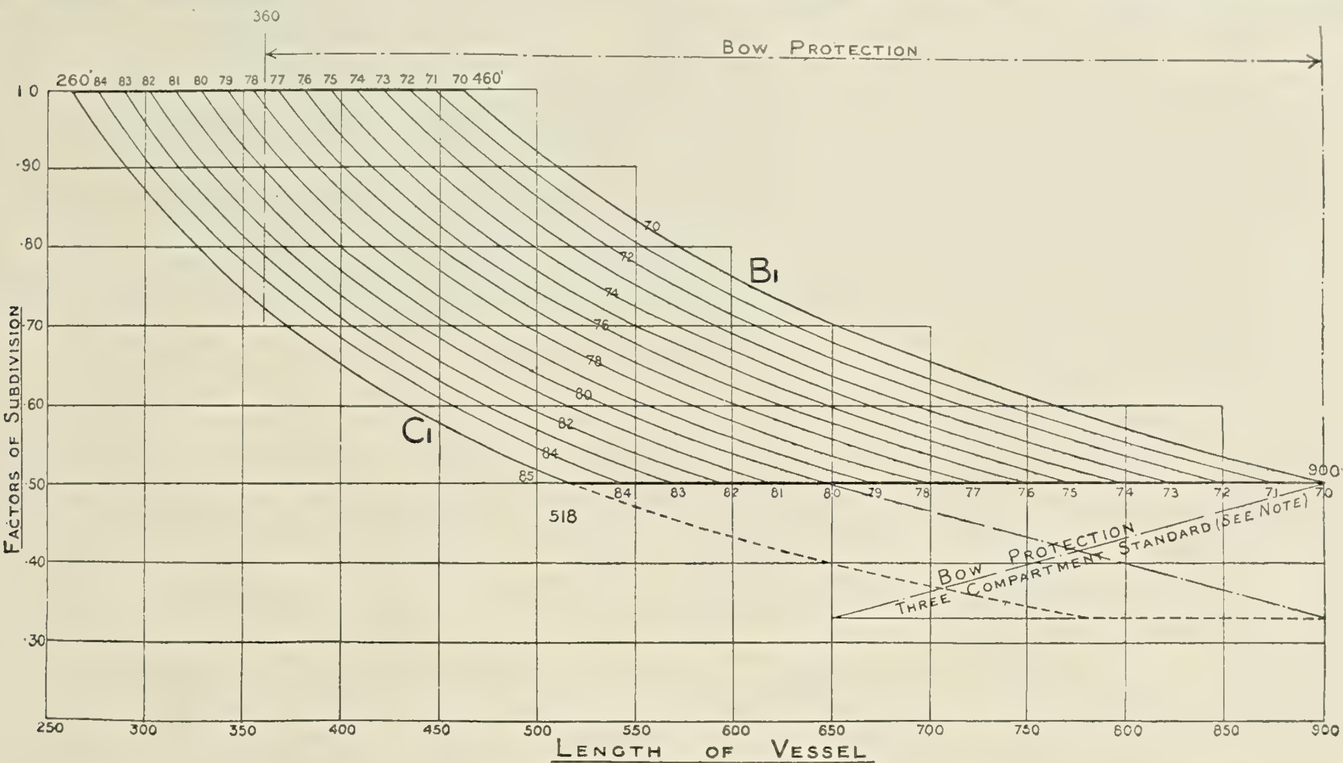
the same are carried above or below the bulkhead deck.

(11) That the Convention curve *C* as amended is applicable to the highest type of vessel primarily engaged in the carriage of passengers.

(12) That the main factor of the criterion might reasonably be based on the permeability of the vessel below the bulkhead deck.

(13) That in addition it would be necessary to introduce a correcting factor based on the total number of passengers carried in the vessel, whether below or above the bulkhead deck, in order to provide for the varied distribution of passengers and of space per passenger.

(14) That this factor might be derived from some specific volume per passenger so applied that where the



1. This diagram does not apply to vessels in the "Home and Coastal" services having length below 360 feet.
2. Vessels with criterion permeability values of 70 percent or below, to have factors of subdivision derived from curve B1.
3. Vessels with criterion permeability value of 85 percent and above to have factors of subdivision derived from curve C1.
4. Vessels with criterion permeability values between 70 and 85 percent to have factors of subdivision obtained by direct interpolation from the diagram.
5. All vessels 360 feet and above to have bow protection of either a "two" or "three-compartment" standard, and the remainder of the vessel will in no case exceed a "two-compartment" standard.
6. Vessels of 360 feet in length, with criterion values less than given by formula: $u = 104.5 - \frac{L}{13.3}$ to have "two-compartment" bow protection only.
7. Vessels of 360 to 460 feet in length, with criterion values equal to or greater than given by formula: $u = 104.5 - \frac{L}{13.3}$ to have "two-compartment" bow protection, with the remainder of vessel to diagram.
8. Vessels of 460 feet in length and above, to have "two-compartment" bow protection with remainder of vessel to diagram, except in vessels 650 feet and above, with criterion values equal to or greater than given by formula: $u = 105.4 - \frac{L}{25.4}$ where the bow protection will be of a "three-compartment" standard and the remainder of vessel a "two-compartment" standard.
9. A "two-compartment" bow protection signifies that the length of fore-peak and No. 1 hold will together not exceed the floodable length forward.
10. A "three-compartment" bow protection signifies that the length of fore-peak and Nos. 1 and 2 holds will together not exceed the floodable length forward.

Diagram of Factors of Subdivision for Foreign-Going Passenger Vessels

(7) That the curve *C* as laid down in the Convention should be adhered to for vessels up to 550 feet in length, the curve being then limited by a horizontal line drawn at 0.45 factor of subdivision, as shown in Appendix *J*.

(8) That when in any vessel a factor of subdivision of 0.40 or less is complied with, a special mark should be placed on the Safety Certificate to this effect.

(9) That the proposals contained in the Report IIa for special bow protection are satisfactory.

Factors of Subdivision

(10) That the curve *B* is applicable to vessels carrying mainly cargo with a nominal number of passengers, whether

volume of the space set apart for passengers below the bulkhead deck is greater than the product of the total number of passengers on board multiplied by some specific volume per passenger, the criterion could be applied without correction, but that where the total number of passengers multiplied by some specific volume per passenger exceeds the volume of the space set apart for passengers below the bulkhead deck such greater volume should, for purposes of the criterion, be substituted for the lesser volume.

Note.—The French delegation expressed their dissent from Recommendations 12, 13 and 14.

The Norwegian delegation desired further opportunity to test the practical application before concurring.

(15) That Articles 2 and 3 of the Convention should be read to mean that any ship which was not at any point in her voyage at a distance of more than 200 sea miles from a sea coast might be exempted from the provisions of the Convention.

Part II

(16) That as a provisional basis for further study the nominal number of passengers to be associated with curve B_1 should be $\frac{L^2}{1,000}$, where L is the length of the vessel in feet, and that, if possible, this allowance should be embodied in the scale factor of the criterion.

(17) That subject to international agreement on seasonal limits, the subdivision load line should be subject to seasonal variations, these being dealt with as proposed in the International Committee's Report in connection with deck cargoes.

Determination of Permeability

(18) That the British suggestion for the determination of permeability contained in Appendix VII was satisfactory and should be accepted, but that the passage commencing line 6 should read as follows:

"Where $h =$ the mean depth below the bulkhead deck of the 95 percent spaces as defined in the present Board of Trade Regulations (exclusive of double bottom, peaks and tunnels) reduced in the proportion which the mean length of such spaces bears to the *mean* length of the vessel measured between the forward machinery space bulkhead and the collision bulkhead, or between the *mean* position of the aft machinery space bulkhead and the *mean* position of the after peak bulkhead. The mean depth is to be measured from top of deck to top of deck at center line.

$H =$ the depth of the vessel from the top of keel to the margin line midway between the end of the machinery space and the forward or after end of the vessel.

$c = o$ for forward end, 1 for after end in single-screw vessels, and 2 for after end in twin-screw vessels, *and 3 for triple-screw vessels.*"

(19) That the mean length of any compartment should not exceed the permissible length, and that no compartment having a mean length of less than 25 feet should be considered as forming part of the watertight subdivision of the vessel.

(20) That more than two alternative load lines should be permitted.

(21) That Article IX (1) of the Convention should be amended to read as follows:

"When the factor of subdivision is equal to or less than .5 it may be doubled in order to give at any point of the ship's length the total length of two adjacent compartments; but, in that case, the length of the shorter compartment of any pair should not be less than one-quarter of the total length *of the two adjacent compartments.*"

Steps and Recesses

(22) That the Regulations for steps and recesses as contained in the Convention should be amended to read as follows:

Recesses.

"That no part of the sides of the recesses should be nearer to the side of the ship than 6 feet, or one-sixth of the breadth, whichever is the greater."

Steps.

"That, whatever the factor of subdivision, the total length of the step in any bulkhead should not exceed 2 percent of the ship's length, but that where the factor of subdivision is .5 or less, the length of the steps may be increased by 3 m., or 10 feet."

The report was signed by the following: Thos. Free, Australasia; A. Leenaers, Belgium; A. S. M. Nicholls, Canada; J. A. Koerbing, Denmark; A. M. Nizery, France; M. Warnholtz, Germany; Kenneth S. Anderson, Great Britain; W. J. Oderwald, Holland; E. Benvenuti, Italy; N. Ohtani, Japan; J. Bruhn, Norway; Michael J. Hayes, Spain; Dan Broström, Sweden.

Appendix VII

Determination of Permeability

It is proposed (somewhat as suggested by the Board of Trade in their Memorandum M. 30084) that the average permeability of the hold spaces below the bulkhead deck should be determined by the formula—

$$\text{Permeability} = 63 + 32\frac{h}{H} + c.$$

Where $h =$ the mean depth below the bulkhead deck of the 95 percent spaces, as defined in the present Board of Trade Regulations (exclusive of double bottom, peaks and tunnels), reduced in the proportion which the mean length of such spaces bears to the length of the vessel measured between the forward machinery space bulkhead and the collision bulkhead, or between the aft machinery space bulkhead and the after peak bulkhead. The mean depth is to be measured from top of deck to top of deck at center line.

$H =$ the depth of the vessel from the top of keel to the margin line midway between the end of the machinery space and the forward or after end of the vessel.

$c = 0$ for forward end, 1 for after end in single-screw vessels, and 2 for after end in twin-screw vessels.

The permeability of machinery spaces is to be taken at 80 percent for steamships and 85 percent for ships fitted with internal combustion engines.

In cases where the "two-compartment" standard of subdivision is required and the permeabilities of two adjacent compartments are different, the length of the compartments are to be obtained by the formula—

$$\frac{u_1}{u_2}(l - l_1)$$

as given in paragraph 18 of the Board of Trade present regulations for the construction of passenger vessels.

Appendix B

The Criterion of Service referred to in paragraphs 35, 38 and 40, in the marginal note on the factor of subdivision diagram, Appendix VIII of the Chamber of Shipping Technical Sub-Committee Report (11A), and explained in the circular letter, dated December 14, 1921, is as follows:

$$u = u_1 + P,$$

where

$u =$ Criterion of Service permeability.

$u_1 =$ the mean permeability of spaces below the bulkhead deck (derived from formula from the longitudinal middle line section of the vessel). (See Appendix A.)

$P =$ a correction for the passenger capacity above the bulkhead deck.

A suitable evaluation of the last term in the equation was found to be—

$$P = \frac{150,000\ N}{L^2 B}$$

where

$N =$ number of passengers accommodated above the bulkhead deck.

$L =$ subdivision length of vessel.

$B =$ subdivision breadth of vessel.

The complete formula, therefore, for Criterion of Service may thus be expressed:

$$u = u_1 + \frac{150,000\ N}{L^2 B}$$

Appendix C

Memorandum Circulated to the Members of the International Committee on Subdivision of Passenger Vessels in April, 1922, for the Meeting of the Committee Held in May, 1922.

It is anticipated that the committee will, in the first instance, proceed to a general discussion of the Report of the Technical Sub-Committee of the Chamber of Shipping dealing with the subdivision of passenger vessels (11A), which was handed to the representatives of the various countries at the preliminary meeting held on November 25, 1921.

After such general discussion, it is suggested that the following specific questions involved in the Report should be considered:

(1) Whether the general nature of the curve C_1 contained in the Report is acceptable for the highest type of vessels primarily engaged in the carriage of passengers.

It should be observed that curve C_1 is almost identical with the curve C recommended by the bulkheads committee, which has

Motorship Bintang, Owned by the East Asiatic Company

Small Motor Cargo Ships for the Eastern Trade

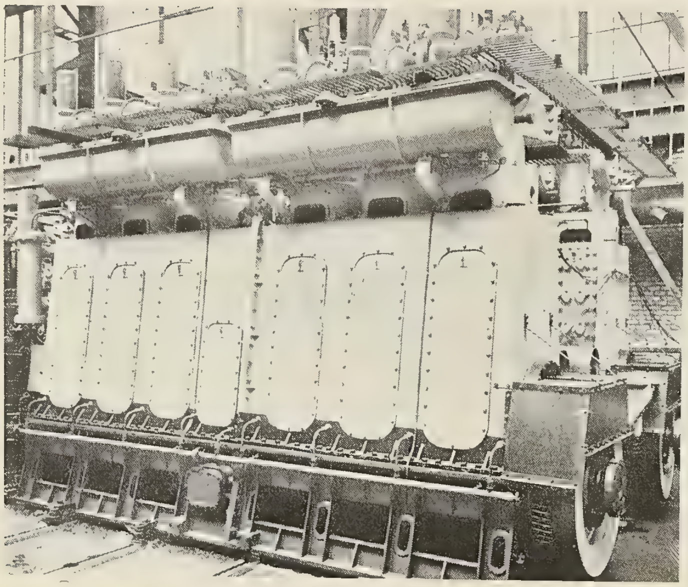
Motorships of About 2,000 Tons Capacity Equipped with Twin Screw Propelling Machinery—Auxiliaries Are Electrically Driven

By Our Special London Correspondent

WHILE chief interest in European shipping circles has lately centered around the numerous motorships of comparatively large size that have been turned out, varying mainly from 6,000 tons to 14,000 tons deadweight, the problem of the application of the oil engine to smaller vessels for specialized services has not been overlooked. In the opinion of many operators, there is a particularly wide field for this class of craft, on account of the low fuel consumption of the Diesel engine, which permits of a large radius of action without the fuel bunkers occupying too large a portion of the available space on the ship, as may be the case with small steamers trading on long routes. In some of these vessels, perhaps the majority, single screw machinery of the long stroke type has been installed, since the power required seldom exceeds 1,000 shaft horsepower. Probably the tendency will be increasingly in this direction, but it is noteworthy that two interesting small motorships, which have just been completed, are both equipped with twin screw plants, although the power does not exceed that stated above.

These two vessels are both destined for service in the East and will not return to European ports except for periodical survey. It is a proof of the confidence which shipowners now place in the oil engine, that such ships are allowed to

Twin Screw Motorship Dumra, Built for the British India Steam Navigation Company



One of the 500 Brake Horsepower Diesel Engines Installed in the Dumra

proceed to their destination immediately after the trials, and will trade for several years on end in parts of the world where possibilities of repairs being effected to the machinery are extremely small.

Vessel for Eastern Coastal Service

One of these new motorships was built in Denmark, to the order of the East Asiatic Company, whose fleet now consists almost entirely of oil engined vessels. The *Bintang,* as she is named, is intended for coastal service in the East, and is 284 feet in length, having a beam of 44 feet and a depth of 28 feet.

She is equipped with two six-cylinder Diesel engines of the Burmeister & Wain type, with cylinders 19¾ inches bore, and 26 inches stroke. Each develops about 700 indicated horsepower, or 525 brake horsepower, when running at about 150 revolutions per minute, and the design is practically identical with that of the larger Burmeister & Wain engines, built in sizes up to 3,200 indicated horsepower. Although there is much to be said for the propulsion of ships of this size, by single screw machinery, it is claimed that owing to the higher speed of revolution possible with a twin screw plant, such an arrangement allows of an actual reduction of machinery weight, as compared with the single screw ship. On the other hand a marine engineer naturally prefers machinery operating at low speed, while the advantage of having only six cylinders in a ship instead of twelve is self-evident.

The *Bintang*, as is usual on most modern oil engine vessels, is equipped with electrical auxiliary machinery, two Diesel driven generating sets being located in the engine room. The exhaust gases are discharged through pipes alongside the mast, and no funnel is provided.

The Dumra Has Passenger Accommodations

The second small motor vessel which has lately been completed is a more interesting type than the *Bintang.* This is the *Dumra* which was constructed for the British India Steam Navigation Company, for their service on the West African coast. The capacity of the hold amounts to just over 2,000 tons, in addition to which first and second class cabins are arranged amidships around the machinery casing for about 40 passengers. The vessel has a length of 280 feet, the beam being 43 feet 6 inches, the draft 17 feet 6 inches and the molded depth 24 feet. The loaded speed is 11 knots and the designed output of the machinery 1,000 shaft horsepower.

The two Diesel engines in this vessel are of a new type built by the North British Diesel Engine Works of Glasgow, the manufacturers who have recently devoted their attention to a double acting two-cycle Diesel engine of large power, which they are now building at their works. The small motors of the *Dumra,* however, are of the normal single acting four cycle construction, with six cylinders 15 inches diameter and 30 inches stroke, developing their power of about 700 indicated horsepower at 165 revolutions per minute with a fuel consumption of approximately 0.45 pound per brake horsepower hour.

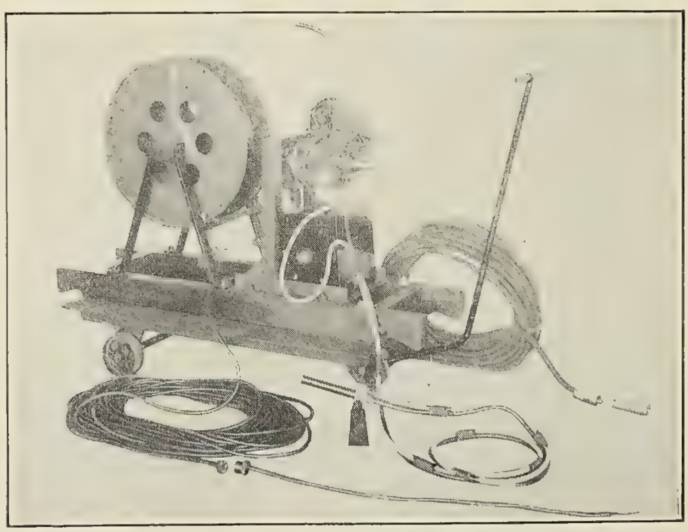
Although these engines are new in design there is little that is novel in their construction. The cylinders are carried on a heavy crank case supported on the bedplate, the cylinder covers and liners being separately cast. The usual four valves in the cylinder head are operated by cams on a camshaft, which is moved in the longitudinal direction when it is desired to go astern, thus bringing the astern cams below the valve operating levers. This movement for reversing is effected in the ordinary manner, through the agency of a compressed air servo motor controlled from the starting platform. There are two starting levers, one for the admission of compressed air, or fuel, to each set of three cylinders, this being a fairly common arrangement. The pistons are cooled with lubricating oil which is somewhat unusual but sea water is used for the cylinder jackets.

Except for the air compressors which are coupled direct to each propelling engine, most of the auxiliary plant is independently driven by electric motors, this including the circulating water and the lubricating oil pumps, etc. Two two-cylinder Diesel engines are installed in the engine room driving 50 kilowatt dynamos for the supply of the necessary power. These are in addition to the large vertical boiler providing steam for the operation of the steam winches.

Portable Semi-Automatic Arc Welding Set

In order to increase the applicability of its semi-automatic arc welding apparatus, and adapt it for use in any place where current for welding is available, the General Electric Company is now building a portable set. This comprises a complete semi-automatic equipment, with support for a wire reel, mounted on a small truck that can be pulled over the shop floor by hand, or lifted by a crane. The complete outfit weighs about 400 pounds.

The welding equipment consists of a semi-automatic lead, an automatic welding head, with control, and a standard for



The Set Can Be Used Wherever Welding Current Is Available

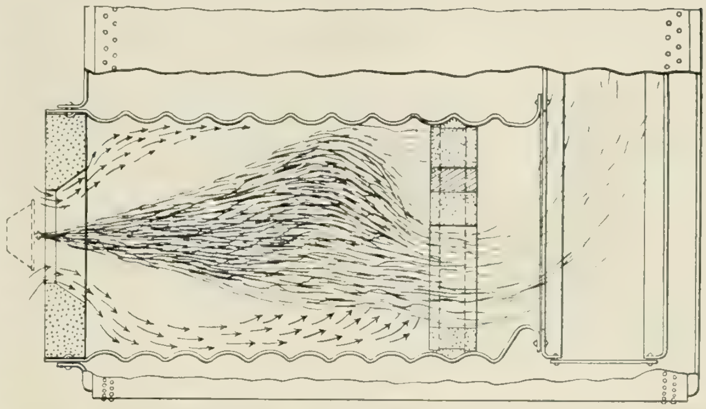
holding a reel of electrode wire. Power is supplied to the arc through a flexible cable with a plug for attaching it to the nearest welding circuit. The reel carrier is equipped with a brake and designed to take any size reel up to 2½ feet in diameter.

The portable outfit should be valuable in repairing parts of machines in place when these parts are too bulky, inconvenient, or otherwise impractical to move, and for doing routine welding of all sorts, such as filling holes in castings, welding seams in pipes or tanks, or other work of a similar nature. Besides the saving in time and trouble due to the portability of the outfit, its use will save both time and material in welding.

The electrode is fed continuously, the number of interruptions are reduced and less skill is required by the operator to make a good weld than is the case with ordinary hand welding. Material is saved by eliminating the waste ends which usually amount to at least ten percent of the total amount of electrode wire used.

Front Arches and Retarders Aid Combustion in Oil Burning Furnaces

RETARDERS made of refractory brick have been developed by the T. G. Egan Refractory Engineering Company, Inc., New York, to aid combustion in furnaces in which oil is used. The accompanying diagram shows the arrangement of the retarder and also the front arch built by the same company installed in a Scotch marine boiler furnace. The retarder is built of blocks made to meet the actual furnace dimensions, tongued and grooved so that when placed in position they are firmly locked, making falling or warping impossible.



Front Arch and Retarder Installed in Furnace of Scotch Boiler

The retarder acts in a manner to retain the gases in the furnace and, because under the action of the flames it becomes incandescent, the gases are ignited causing complete combustion, increasing the carbon dioxide and greatly decreasing preventable fuel losses. It is stated by the company that savings of more than five tons of fuel per day have resulted from the use of the Egan retarder.

The front arch also installed in the furnace is made in sections each of which is provided with a locking device which insures the arch from falling. The arch is very easy to install and promotes the economy of boiler operation.

Fitting Out Uncle Sam's Great Lakes Navy for Practice Cruises

On the Great Lakes the United States has only one war vessel, the U. S. S. Wilmette, the hull of which is that of the ill-fated Eastland, which capsized in the Chicago River on July 24, 1915. The photograph shows the Wilmette at the foot of Randolph street, Chicago, being fitted out for a series of two-week cruises on the Lakes, manned by naval militiamen and citizens who desire to make the voyages.

Marine Boiler Water Treatment

How to Prevent Scale and Corrosion — Water Testing Apparatus—Chemical Changes in a Boiler

By Commander J. B. Patton, U. S. N. (Retired)

SEA water and air are the enemies of the marine boiler. Corrosion and scale are the damages caused by these enemies. Sea water, alone will cause scale but it will not cause serious corrosion unless air is present. By "corrosion" is meant local pitting, which quickly destroys tubes and plates, and not common rust, which is of little importance. The latter is found in tanks and bilges, sometimes ½ inch thick and formed by a thin film of iron. The rust is light in density, and contains only a percentage of iron.

But as all water has some air in it, we cannot keep air entirely out of the boiler. The Weir feed water heater extracts most of the air, and ships with this heater have very little boiler corrosion, even when using salt water in the boilers. Experience proves that a small amount of sea water always gets into the boilers so we cannot expect to keep sea water and air entirely out of boilers. But we can win the battle, if we keep the salt down to a low quantity (say ⅛ by salinometer, or 150 grains of chlorine in a watertube boiler, and double that amount in a Scotch boiler), because a small amount of soda ash will neutralize that amount of salt water and prevent both corrosion and scale.

If the density gets higher, considerably more soda will be required and it should be put in, unless priming of the boilers forbids further addition of soda. If sufficient soda cannot be used, some scale may be formed but there will be no serious corrosion, if there is no air in the water. The amount of soda required was formerly guessed at but in modern practice the amount required is indicated by a daily test of the boiler water for alkalinity, as explained later.

Condensed Rules (Approved by Good Authorities)

(1) Buy a practical instrument for testing boiler water for alkali and chlorine (salt).

(2) Try to keep salt water out of the boilers. If the condenser leaks, stop and repair it, if possible.

(3) Try to keep air out of the boiler water.

(4) Test the water in the filter tank each watch for chlorine. If it contains under 40 grains, you can not taste the salt.

(5) Test the water in the boilers daily for alkali and chlorine, and maintain *an alkalinity of* 10 *to* 20 *grains per gallon* by putting daily additions of soda ash in the filter tank. As a starter, when filling a single-ended Scotch boiler of about 26 tons' capacity, put in 20 pounds of soda ash (other size boilers in proportion). This will start you off with an alkalinity of 20 grains to the gallon. Then a daily addition of one pound of soda ash to the filter tank for each boiler in use will be about right, unless the condenser leaks considerably (admitting salt water and neutralizing the soda). In this case, considerably more soda will be required to keep up the alkalinity. The alkali test will indicate whether the daily addition of soda ash is to be increased or diminished. There is an advantage in having the soda in the boiler before the salt gets in.

(6) It is best to have a ten-gallon water tank over the filter tank and to put the daily allowance of soda ash in it. A pipe and valve should be arranged so the mixture will drip into the filter tank all day long. This keeps the water alkaline and prevents corrosion around the discharge end of the internal feed pipe. But if you are unwilling to take this trouble, put it in once a day.

The Navy plan of removing air from feed water appears to be a good one; it is an adaptation of the Weir system to a high pressure heater. A quarter-inch pipe is run from the top of the feed heater or feed line and led back to the filter tank, with a valve kept slightly open. The air and also any oil present come back to the filter tank. The small amount of water coming back is not important. The high pressure tends to keep the air in solution but the high temperature tends to release it.

The internal feed pipe arrangement of the Babcock and Wilcox boiler is a good plan and might well be adapted to the Scotch boiler. This pipe discharges over the downcomer headers, but just under the water level, so that the air escapes to the steam space and does not follow the water to the bottom of the boiler.

Zincs

There is good reason to think that zincs are not needed when the water is kept alkaline. But the water is not always kept alkaline, and when the density is high, it may not be possible to keep it alkaline. For this reason, the zincs should be retained.

Action in the Boiler

In order to visualize what takes place in a boiler when salt water and soda ash are present, the following example is given:

Consider a single ended Scotch boiler, capacity 7,000 gallons or 26 tons, a very common size. As there are 7,000 grains in a pound, it happens that "pounds per boiler" and "grains per gallon" are the same thing for this size boiler. Suppose the boiler filled with fresh water, and 20 pounds of soda ash added. An alkali test should then show 20 grains per gallon. If one pound of soda be added daily, then after 30 days' steaming the boiler will have a total of 50 pounds of soda ash, or 50 grains per gallon. If the density has gone up to 120 grains of chlorine, or 1/10 by salinometer, then 40 pounds of the soda will have neutralized all the acid forming and scale forming elements in the boiler, and there will be 10 pounds of free soda left, or 10 *grains per gallon* of alkalinity by test.

As a matter of fact, the alkali test will probably show around 15 *grains per gallon,* on account of a very *important fact.* When an alkali test is made, the first ten grains may be a false alkalinity due to carbonates present, which does not mean the presence of free alkali. An actual test of water from the S. S. *Castletown* showed water of 3 grains alkalinity, and also containing 107 grains of magnesium chloride, showing the water to be highly corrosive and *potentially* acid. Since the days we stopped using animal or vegetable oils for internal lubrication, there is no such thing as boiler water giving an acid test or reaction. Boiler water containing a little salt may be *potentially* acid or corrosive, if it shows an alkali test of less than 5 or 10 grains. It may not be even "neutral" unless it shows this alkalinity. These facts are supported by good authorities in this country and in England and will be referred to later.

Condenser Leaks

If the condenser leaks sufficiently to supply the "make up" or "extra feed," the density in the Scotch boiler will go

up to ⅛ that of sea water, or 150 grains, in a day; in a watertube boiler, 6 to 8 hours. The filter tank water will have a density of about 40 grains per gallon, which cannot be detected by taste. This shows the importance of making frequent tests of filter tank water for chlorine.

Alkali

The standard alkali is soda ash (powder), or carbonate of soda. Sal soda (crystal) is the same thing, but only about half as strong, as it contains 60 percent water of crystallization. Some prefer it because it is easily handled. In a hot place it will melt in its own water.

Caustic soda, while chemically different, may be said to be, very roughly, about 1½ times as strong as soda ash. This is referred to later. Its use is recommended by some good authorities.

Lime will prevent corrosion and is about 1½ times as strong as soda ash but it is hard to dissolve and does not prevent scale but rather increases it, so its use is not recommended.

Boiler compounds of unknown formulæ are to be avoided. The Navy boiler compound is probably better than pure soda ash. Its formula is said to be as follows:

95 percent soda ash;
4 percent di-sodium phosphate (which is said to prevent priming);
1 percent organic matter (which is said to keep scale from settling on the heating surface. This is in line with the old idea of putting molasses, potatoes or sawdust in a boiler).

Shore Water

Shore water should be tested for chlorine (salt). Many shore waters contain considerable limestone and calcium sulphate, which are scale forming and are not indicated by the chlorine test. But if soda ash be used, they will be made harmless.

Blowing

Every pound of sea water that goes into a boiler (unless neutralized with soda) produces some hard scale. You blow out the salt but not the hard scale. Unless the feed water is fresh, it is best not to blow.

If the condenser leaks, it is best to stop and repair it. If this cannot be done, it is best not to blow unless the boilers prime, or the density gets up to 2/32, when salt is said to begin to deposit in a high pressure boiler. In any case, it is useless to blow unless the feed water is a great deal fresher than the water in the boiler.

Approximate Conditions in a Boiler Containing Some Sea Water. Quantities Shown Are Grains Per Gallon, or Pounds Per Boiler in a 26-Ton Boiler

1	2	3	4	5	6	7	8
Ounces	Density by Salinometer	Chlorine	Total solids	Salt	Hard scale	Corrosive matter	Total soda ash required to neutralize 6 and 7
5	1/32	1200	2100	1700	100	300	400
2½	½ of 1/32	600	1050	850	50	150	200
1¼	¼ of 1/32	300	525	425	25	75	100
⅝	⅛ of 1/32	150	262	212	12	37	50

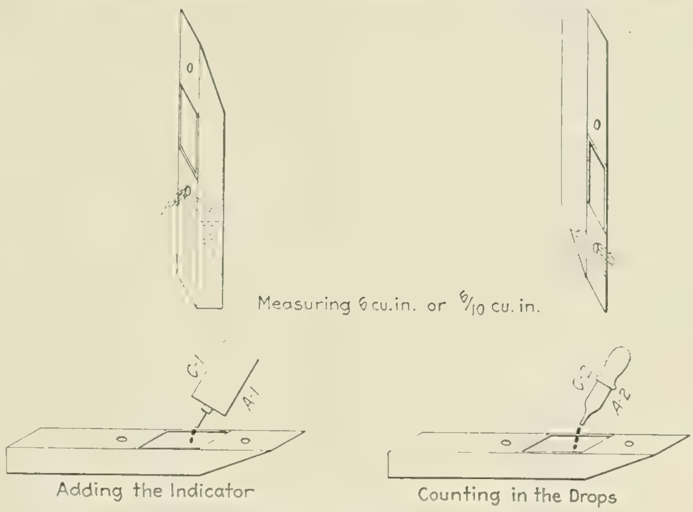
Water Testing Apparatus

There are several types of chemical outfits which may be purchased. All of them use the titration method. The alkali is neutralized by a measured quantity of acid. The chlorine is precipitated by a measured quantity of silver nitrate. Some of these outfits measure alkali only; some measure both alkali and chlorine. All of them are made of glassware, which is liable to be broken on board ship.

The Boiler Water Testtool (Invented by the writer).—This is a new instrument for testing water for both alkali and chlorine. It is sold by The Marine Works, Inc., 31 Coenties Slip, New York City. In this set, glassware has been practically eliminated. There are only five movable articles and these are made of metal or rubber. The measuring is automatic and there is no necessity for peering at faintly graduated glass tubes.

There is a white enameled ironware measuring and mixing tray in which the water sample is measured and tested, as explained below. The two indicators are in metal cans with nozzles. The acid and silver solution are measured by standardized hard rubber droppers, giving a drop of constant size.

To measure a sample of 6 cubic inches of water, the Testtool is dipped full of water and then held vertically, big end down, and the excess overflows and the water level falls even with a hole in the tray, thus retaining 6 cubic inches. The Testtool is then held horizontally, ready for the test.



Sketch Showing Operation of Testtool

This size sample is used for alkali test, or for testing fresh water for chlorine.

If held with the small end down, a sample of 6/10 cubic inch is measured. This size sample is for making chlorine test of salty water.

For the alkali test there is a can *A-1* (oil can type) containing Phenolphthalein indicator of which *several* drops are added to the water sample and which should turn red. Bottle *A-2* contains a standard acid and has a *standardized dropper*. The acid drops are counted into the tray, until the red color disappears; the number of drops used indicates the grains per gallon of soda ash.

For the chlorine test there are: Can *C-1*, containing potassium chromate indicator, and bottle *C-2* (with dropper), containing nitrate of silver solution. When testing *fresh* water, 6 cubic inches are used and *several* drops from *C-1* are added. Then sufficient drops from *C-2* are counted in till the water turns *red*. Each drop of nitrate of silver indicates one grain of chlorine. When testing *salty* water, 6/10 cubic inch of water is used and each drop of *C-2* indicates 10 grains of chlorine.

During this test there is nothing to break or even fall off the desk, for the Testtool is held in the left hand and the dropper in the right hand. The above has been found to give very accurate results.

Chemical Changes in a Boiler

The following is a brief statement of the changes which are said to take place in a high pressure boiler containing some sea water and soda ash:

Composition of sea water	Grains per gallon
Calcium carbonate	9
Calcium sulphate	114
Magnesium sulphate	134
Magnesium chloride	244
Sodium chloride	1706
	2207

1. The sodium chloride remains in solution, but may begin to deposit, if the density reaches two or three thirty-seconds.
2. The calcium sulphate forms hard scale but, if soda ash is present, calcium carbonate goes to the bottom as sludge and sodium sulphate remains in solution.
3. The magnesium sulphate is corrosive and may form scale, but the soda neutralizes it, precipitating the magnesium as sludge, sodium sulphate remaining in solution.
4. The magnesium chloride is corrosive but the soda neutralizes it, precipitating the magnesium as sludge, sodium chloride remaining in solution.

Air in Water

When corrosive salts are present, air and carbon dioxide are stimulating factors and increase corrosion immensely. There is reason to believe that air in fresh water is harmless. There are reports of corrosion of feed heaters at stationary plants by air in the water but probably some corrosive salts are present.

At the Naval Proving Ground, Indian Head, Maryland, there are watertube boilers with non-condensing engines, that have been in use many years without corrosion. The feed water comes from an artesian well by air lift pumps, and is strongly charged with air. It is pumped into the boiler cold. This water is practically pure having only a trace of silicon.

The power plant boilers at the Norfolk Navy Yard used 100 percent "make up" feed water and the water was well aerated, coming from a lake. There was no corrosion after years of service.

The tugboat *Leader* in New York harbor has a boiler forty-four years old, with the original tubes. The engine is non-condensing, and the feed water is New York city water, which contains air, of course, but no corrosive salts. The air did no harm here.

Alkali

Some years ago, the Scotch boilers of a new naval ship had to be retubed after two years' service. After a short time the new tubes began to pit. Within a year the tubes were giving out at the rate of one a week. No alkali had ever been used in the feed water. At this time the *storekeeper* was told to put two pounds of soda in the feed tank daily. That is absolutely all that was done; the result was that not another tube was lost and the ship ran many years with the boilers tight and sound.

S. S. Castletown.—A test of the boiler water on this ship showed 800 grains of chlorine, 107 grains of magnesium chloride and 3 grains of alkalinity. About 40 grains of soda per gallon had been used but it was not sufficient and the water was potentially acid although it gave an alkali test of three grains. In order to get this alkalinity up to ten grains, indicating an excess of free soda, it would be necessary to add sufficient soda to first neutralize all the corrosive salts present, or over 100 grains of soda ash per gallon.

The names can be given of many ships with good boiler tubes and furnaces thirty years old. On the other hand, many boilers are worn out in ten years or less. The writer was told recently, by a former superintendent of coastwise vessels, that he found the life of Scotch boilers to be about ten years.

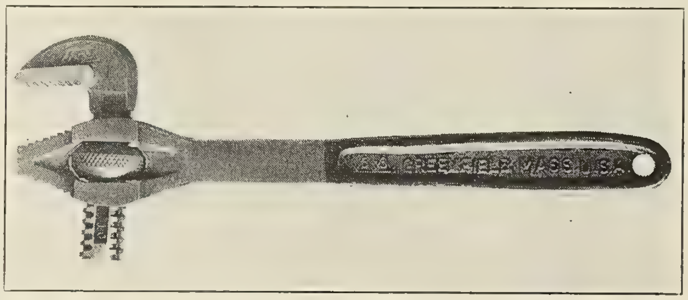
There must be a reason for this difference in durability, and there is no doubt that in most cases boiler corrosion and scale troubles are due to neglect of the simple and well-known rules referred to in this paper.

Reciprocal Inspection of Belgian Steam Vessels Authorized.—Under the provisions of an act of Congress approved March 17, 1906, the Secretary of Commerce, in Department Circular No. 289, dated July 15, 1922, authorized the reciprocal inspection of Belgian merchant passenger steam vessels, so that thereafter the merchant passenger steam vessels of Belgium sailing from ports in the United States and holding unexpired certificates of inspection issued by the duly constituted officers of Belgium shall be subject to no other inspection than such as necessary to satisfy the local inspectors that the condition of the vessel, her boilers, and life-saving equipments are as stated in the said current certificate of inspection. Copies of Circular No. 289 can be obtained on application to the Steamboat Inspection Service, Department of Commerce, Washington, D. C.

Pipe Wrench Designed for Difficult Corners

The Little Giant pipe wrench, embodying several interesting new features, has just been put on the market by the Greenfield Tap & Die Corporation, Greenfield, Mass. This wrench has the "end opening" feature which is familiar to users of machinists' wrenches. Its application to pipe turning can readily be seen by a glance at the illustration.

One important advantage of the Little Giant wrench is the ease with which it can handle pipes in corners, close to walls, and similar confined places. The person using it can set it straight on the pipe as he would a pair of pliers, instead of having to fit the jaws on from the side. There are only three parts, a handle and jaw in one piece, which is drop forged and heat treated; a movable jaw, likewise drop forged and heat treated; and a hardened steel nut. In spite of the absence of springs the wrench is said to take hold and release instantly at the option of the user.



Little Giant Pipe Wrench Embodying New Principle of Design

The new wrench has been designed for maximum strength, the 14 inch size having successfully withstood stresses in excess of 4,700 inch pounds without slipping or bending. Yet owing to the elimination of extra parts the wrench is relatively light in weight.

Another feature is the double set of teeth on the main jaw. The movable jaw can be engaged at the option of the operator with either of these sets of teeth with consequently lengthened life. On the large sizes, 14 inches and greater, two additional sets of teeth are provided, making four in all, and the movable jaw can be reversed to engage these additional sets of teeth, which are below the adjusting nut. This is very useful in connection with certain classes of work, besides tending to quadruple the life of the tool.

The Little Giant wrench is being manufactured in 8-, 10-, 14-, 18- and 24-inch sizes, of which the three smaller sizes are already on the market.

Navy League Designates October 27 as Navy Day.—At the suggestion of the Navy League of the United States, approved by the Navy Department, Friday, October 27, has been set apart as Navy Day on which an opportunity will be given for all the citizens of the country to honor this branch of the service which safeguards our peace and prosperity.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Valve Setting Problem

Q. (1167).—I have a twin screw reciprocating installation, link motion, cylinders 15½ by 26 by 44 inches; stroke, 26 inches; piston valves for high pressure and intermediate pressure inside admission and piston valve outside admission for low pressure cylinder. This particular design gives crossed rods and the approximate leads at full stroke are: High pressure, ½ inch bottom, ⅜ inch top; intermediate pressure and low pressure, 9/16 inch bottom and 7/16 inch top. High pressure valve is a plug valve and the other two stages are ring valves. The steam pressure at engine is 225 pounds.

I desire your advice in regard to the most suitable setting for these valves in order to bring about an economical distribution and consumption of steam and turn up 125 to 128 revolutions per minute at maximum cut-off, so as to be able to get approximately 135 to 140 turns at or about full stroke, as these engines are used in towboat service in the Federal Barge Line and it is often necessary to run out the expansion blocks and get all she has going through swift places.

Would a link motion having open rods be more suitable in your estimation than the present one with the cross rods? These engines were originally built to turn outboard as is the general practice with twin screw installation ships but when placed in this service were required to turn inboard when in ahead motion. To bring this about the crank shafts were merely transposed and to the best of my knowledge no other particular changes were made.

A. (1167).—Your question relative to the resetting of the valves for improved steam distribution is one which for its solution requires more of an investigation than is practicable for the editors of this department to undertake. At best the results which might be reached would be theoretical only and in all probability no better than the present valve setting. Inspection and comparison of your leads with engines of similar proportions and size would indicate the setting to be about the usual practice.

The most reliable and satisfactory results would be obtained by taking top and bottom indicator cards and computing the developed power from each cylinder under various conditions of cut-off, a cut and try process, until the cards show an approximately even distribution of power between the cylinders.

In an engine running in full gear the valve events are the same regardless as to whether the rods be open or crossed but when linked up the events are greatly changed. Lead increases when linking up with open rods but decreases to the point of negative lead with crossed rods.

Steam and exhaust openings decrease with crossed rods linked up, therefore the effect of the advantage of steam expansion is greatly decreased. The above would indicate that far better results would obtain from the use of open rods.

Relative Resistances of Models and Full Size Ships

Q. (1168).—Can you favor me with the facts which govern in the acknowledged standards by which the relative values of efficiency in testing model ships compare with the full size ship? For instance, a model shows 10 percent better results than the others, what will that represent in a full size ship?

A. (1168).—In deriving the resistance of the full size ship from that of the model as obtained from tests, Froude's law of comparison is assumed to apply in so far as resistances other than frictional are involved. This law is briefly as follows: If the linear dimensions of a ship are p times those of its model and the resistances of the latter at speeds V_1, V_2, etc., are R_1, R_2, etc., then at the corresponding speeds of the ship, $V_1 \sqrt{p}$, $V_2 \sqrt{p}$, etc., the resistances of the ship will be $R_1 p^3$, $R_2 p^3$, etc.

The total resistance, either ship or model, is made up of the frictional, the wave making, the eddy making, etc. The frictional resistance, as above noted, does not follow the law of comparison. It varies with $(\text{speed})^{1.825}$ and the frictional coefficient is different for long and short surfaces. The frictional resistance is generally estimated from a formula of the form $R_f = f\,S\,V^{1.825}$ in which S is the area of wetted surface in square feet, V is the speed in knots, and f is the coefficient experimentally determined for different lengths of wetted surface. This formula applies both to ship and model.

The total resistance of the model being known at a given model speed, the frictional resistance of the model is computed by the formula referred to above and deducted from the total model resistance. The remaining model resistance is expanded by Froude's law to obtain the residuary resistance of the ship at the corresponding ship speed. The frictional resistance of the ship is then computed similarly to that of the model. The total ship resistance is the sum of the residuary and the frictional ship resistances as just found.

A 10 percent difference in the resistances of two models may indicate a 10 percent difference in the resistances of the two ships represented but this does not necessarily follow. The relative values of the residuary and frictional model resistances for the same model as well as the differences in these resistances as between model and model affect the relationship between the ship resistances. It is a matter of calculation for the individual case.

Wood vs. Steel for Houseboat Construction

Q. (1169).—I am considering building a shallow draft houseboat and have already prepared plans which contemplate a hull 60 feet in length, 20 feet in breadth with a draft of 18 inches. I had originally intended to build the hull of wood but have thought that steel might be preferable because of its non-inflammable nature. Please discuss the relative values of wood and steel for boats of this type.

A. (1169).—Wood is almost always used in the construction of hulls whose lengths are less than 100 feet. This is perhaps due principally to the fact that there are many small boat building concerns scattered throughout the country which, while they are capable of building excellent wooden hulls, have neither the plant nor the personnel necessary to work steel. Therefore, one may build in wood and avoid meeting the heavy charges for overhead which the equipment necessary to work in steel involves. A steel hull may cost roughly from 30 to 40 percent more than a wood hull of the same dimensions.

It is generally possible to build a small boat of wood on a smaller hull weight than that of a similar steel hull of the same dimensions. This is because the members of the structure which are required to resist the bending and racking strains on the wooden boat as a whole are of ample size to withstand the local forces met in service while their

weight is less than that of the steel members designed for equivalent service in a steel hull.

In boats of small displacement it is necessary to use very thin plates and very light shapes in order to build a steel hull on the same weight as a wooden one. It results that the wooden hull is stronger locally than the steel hull. Because of this, the steel hull may, after a comparatively short period of service, show so many dents or dishes in the plating as to give it a very unsightly appearance even though entirely seaworthy.

Further, the insulating of a steel hull against heat and cold and the elimination of sweating present a somewhat more difficult problem than the ceiling of a wood hull.

In spite of the foregoing there are strong arguments in favor of the steel hull once one accepts its increased cost.

A properly designed steel hull is stronger against bending and racking forces than a wood hull. It is also stronger against longitudinal shearing forces.

It is tighter and freer from vermin than a wood hull.

It is not subject to water logging or soakage, with the increase in draft incidental thereto, and is, as you suggest, safer from damage by fire.

When the hull length approaches or exceeds 100 feet, the scantlings necessary in a steel boat to satisfactorily meet the bending and racking forces become sufficient so that minor bumps are easily withstood without local damage. Also at about this length the steel hull begins to have a real advantage over a wood hull from the weight standpoint.

International Shipping Conference Committee Reports

(*Continued from page* 648)

been slightly adjusted to give factors of subdivision which vary inversely as the length of the vessel when the origin of the curve is fixed at a length of 260 feet with unity factor.

(2) Whether the general form and position of the curve B_{11} as suggested in the Report, is generally acceptable, observing that it is now admitted curve B of the Convention, which is supposed to apply to a mixed type of vessel, is too stringent for vessels carrying mainly cargo and few passengers.

As regards the curve representing the lower standard of subdivision on the diagram, it should be remembered that whatever the number of passengers carried on a vessel, the appropriate factor of subdivision will always be decided by the Criterion of Service value obtained for that vessel.

(3) Whether the form of Criterion of Service suggested in the Report (11A) and the subsequently explanatory letter of December 14, 1921, is generally acceptable or whether, having regard to the subsequent note, a modification of this form of criterion is desirable.

(4) To discuss the limitations within which the curves B_1 and C_1 shall be applicable, having regard to the fact that below a certain length of vessel it is not economically possible to provide a one-compartment standard throughout the length, and that at and above certain higher limits of length all safety requirements seem to be reasonably met when any two adjacent compartments throughout the length can be flooded.

With regard to the Criterion of Service, it may be desirable to offer some further remarks.

It is extremely necessary that the Criterion of Service should be determinable in the early stages of the design. It can only, therefore, take account of the main factors involved.

It is suggested that the factors which may be expected to be known at this stage are: . Length, breadth, depth to bulkhead deck, draft, displacement volume, speed, horsepower, permanent passenger accommodtion below the bulkhead deck and number of passengers.

These factors should be combined in such a way that the numerical result obtained will closely approximate to the numerical values obtained from the actual ship when completed. They must also be combined in such a way that they will fairly differentiate between ship and ship in relation to the passenger-carrying function. It is to be observed that the passenger-carrying function must reflect the ratio which the space given to passengers bears to the total space available in the ship, subject to a correcting factor which shall to some extent take account of machinery space or horsepower or speed.

Express Liner Construction May Follow Passage of Shipping Bill

BELOW is published an extract from a letter of Chairman Lasker of the Shipping Board to Senator King of Utah which was written in refutation of remarks made by the senator following a printed resolution which he introduced in the Senate mentioning the financing by the Shipping Board of private ship construction in the event the shipping bill passed. Chairman Lasker said in part:

"Let me say that I never made any statement that the Shipping Board intended to advance private parties $25,000,000 for the construction of a ship, nor did I ever make any statement that anyone could, in good faith, construe to mean any such thing.

"In reply to inquiries from newspaper men as to whether the Shipping Board had any requests for loans for construction purposes, I stated that we had no formal requests but that in an informal way a new company that was being projected on paper (but for whose ultimate formation I could in no wise stand guarantor) had asked whether they could borrow as much as $25,000,000 providing they put $45,000,000 of their own money into building new ships, of which two would be 70,000-ton ships; in other words if, out of the Construction Loan Fund which the Shipping Board is authorized by law to create, the Shipping Board was prepared to lend $25,000,000 for which we would get as security $70,000,000 worth of ships.

"Of course, I could make no reply to the tentative question I explained to the persons making the informal inquiry that they would have to formally organize their company, pay in their money, submit the definite plans of the ships, and at such time the matter be taken up with the entire Shipping Board for consideration.

"I am happy to state to you, though, that I was much impressed by the stability of the people who made the tentative inquiry, and feel that they are serious in their desires to build ships that will be crown jewels in our merchant marine. Whether or not they will proceed as they stated, will depend on the fate of the pending bill to aid merchant shipping, but in the interim they are having plans drawn for their ships.

"The most encouraging moment in the history of America's merchant marine will be that moment when private parties actually subscribe $45,000,000 of their own money to put into $70,000,000 worth of ships and the government will receive full security for its advance."

NEW BOOKS

How to Start Marine Engines in a Cold Ship. By W. J. Woodcock. Size, 7¼ by 4¼ inches. Pages, 153. Diagrams, 13. New York, 1922; Spon and Chamberlain.

This is a valuable reference book, prepared by a sea-going engineer who holds licenses for operating ocean steamers and motor vessels of unlimited tonnage, giving full instructions for setting all the valves and operating single and cross-compound turbines, triple expansion engines, semi-Diesel engines and a full Diesel electric drive on ships. It is a thoroughly practical book and is written so that men in the engine and boiler rooms of modern sea-going vessels may become familiar with the equipment and with a systematic manner in which to handle it so that they can safely start a marine engine under any condition, or in a cold ship, without unnecessary loss of time and without any feeling of uncertainty as to the proper and safe procedure. Simplified diagrams show the location of all valves and piping in each case and the instructions for operating the machinery from the time the ship is cold until it has completed its voyage are as clear and concise as if given by the engineer on watch.

NEW BOOKS

Diesel Operators' Guide

Reviewed by A. B. Raymond*

The 20th Century Guide for Diesel Operators. By Julius Rosbloom and Orville R. Sawley. Size, 6¼ by 8⅞ inches. Pages, 637. Profusely illustrated. Seattle, Wash., 1922: Western Technical Book Company, Inc.

Those interested in the development of the marine Diesel engine have been looking for the publication of a book covering this subject in a comprehensive way. Messrs. Rosbloom and Sawley have undertaken to fill this gap and have compiled a mass of information and collected a large number of illustrations which make their book a very interesting and handy reference hand book.

The first three chapters cover such subjects as: Technical Terms, Theory and Miscellaneous Formulæ. Chapters 4, 5 and 6 cover the Principles of Diesel Operation, Liquid Substances and Questions and Answers on Diesel Operation. Chapters 7, 8 and 9 deal with Fuel Feed and Ignition, Principles of Construction, Auxiliary Machinery and Accessories.

Chapters 10, 11 and 12 treat of Detailed Description of Diesel Engines, Diesel Electric Propulsion and Low-Compression Oil Engines. Chapters 13, 14 and 15 cover Compressors, Pumps and Batteries.

The last chapter gives the United States Rules for Licensing of Engineers on Motorships, Lloyd's Rules and Extracts from Rules of American Bureau of Shipping.

Both the illustrations and text are well indexed.

Information in varying amounts is given regarding the following Diesel engines: Allis-Chalmers, Atlas-Imperial, Busch-Sulzer, Burmeister & Wain, Dow, Fulton, Junkers, Lombard, McIntosh & Seymour, Nelesco, Nobel, Nordberg, North British, Sperry, Still, Standard, Washington-Estep, Western, Werkspoor, Winton and Worthington.

The semi-Diesel and oil engines referred to are the Baltimore, Bolinder, Cummins, De La Vergne, Fairbanks-Morse, Gulowsen-Grei, Ingersoll-Rand, Kahlenberg, Mietz and Weiss, Petter, Prim, Steinbecker, Vickers and Wygodsky.

The authors have accomplished so much it may seem an imposition to suggest that no mention has been made of many makes which are on the market either here or abroad at the present time, such as: Ansaldo, Armstrong-Sulzer, Beardmore-Tosi, Camellaird-Fullagar, Doxford, Enterprise, Götaverken, Hawthorne-Werkspoor, Johnson, Kincaid, Krupp, Neptune, North Eastern, Pacific, Polar, Schneider, Stephen-Sulzer and Wallsend-Sulzer. Many of the above are built under license from well-known makes but the individual development is often of great interest.

The Diesel engineer also has many problems in connection with the auxiliaries and with the actual installations, such as taking care of the exhaust, foundations, critical speeds and vibration and added information upon these subjects will surely be welcomed.

Some of the formulæ given need a careful checking, as well as the index, and the English might be improved.

OBITUARY

Frank M. Hawkins who has been connected with the Crouse-Hinds Company, 30 Church Street, New York, for a period of twenty-five years, died recently. Mr. Hawkins had been actively engaged in the upbuilding of the business of this company and his loss will be keenly felt by all those associated with him.

George R. Edgcumbe, purchasing agent for the Clyde and Mallory Steamship Lines, New York, died recently at his home in Jersey City, N. J. He had served in various capacities with the Mallory Line for a period of forty-seven years, beginning his career with the company as a clerk in 1875. In his years of steamship service, Mr. Edgcumbe has won the greatest respect from friends and business associates alike.

PERSONAL MENTION

P. J. Farrington has resigned from the staff of the United States Navigation Company.

Elmer E. Froewiss, formerly with the Oriental Navigation Company, is now associated with the Kerr Steamship Company.

Charles Backman has organized the Backman Towing and Transportation Company, Inc., with offices at 15 Whitehall Street, New York.

D. V. Stratton has joined the organization of the Morse Dry Dock & Repair Company and is in charge of the New York office in the Whitehall Building.

Captain James Abernathy, formerly in command of the steamship *M. S. Dollar,* has been appointed port captain of the Robert Dollar Company at New York.

P. R. Crocker has resigned as traffic assistant at the New York office of the United States Shipping Board and on his return from a two months' trip in Europe will enter private business.

Harold Dollar, son of Robert Dollar, has left San Francisco for Shanghai to become Oriental manager of the Robert Dollar Company. He has recently been elected president of the American Chamber of Commerce at Shanghai.

Captain Francis H. Robinson, who has been connected with the Pacific Mail Steamship Company at San Francisco and the California Atlantic Steamship Company for many years, has joined the staff of the Munson Steamship Lines.

Norman B. Beecher, one of the admiralty counsels of the United States Shipping Board, will represent the Board at the meeting of the Comite Maritime at London, October 9-11, to discuss the proposed rules for the carriage of goods by sea.

Charles N. Crowell, naval architect and constructing engineer, has severed his association with William T. Donnelly, consulting engineer, New York, and returned to his home in Cambridge, Maryland, where he has established a temporary office.

G. H. Pouder, of the Export and Import Board of Trade of Baltimore, Md., will give lectures during the second semester of the 1922-1923 sessions, at the University of Maryland, on terminal management and expansion, which will be in conjunction with the university's commercial and economics course.

S. M. Phillips, of the Maintenance and Repair Department of the United States Shipping Board, will conduct the evening classes in naval architecture and marine engineering at the Brooklyn Polytechnic Institute, Brooklyn, N. Y., this year, providing the required number of students register before October 5. Mr. Phillips has conducted this class in past years with success. His experience in the yard, drafting room and naval architect's office give him exceptional qualifications for understanding what the student needs most to prepare him for a good job in the shipyard.

F. W. Leahy, one of the best known engineers in marine circles, has resigned from the management of the New York office of the Diamond Power Specialty Corporation to es-

* Naval architect, Tams & King, New York.

tablish his own business, the Leahy Engineering Company, with offices at 709 Second National Bank Building, Cincinnati, Ohio. The new company is specializing in power plant equipment as well as in several marine lines for river boats.

Rear Admiral D. W. Taylor, U. S. N. (retired), has been engaged as consulting expert in matters of ship design, construction and operating economy with the American Ship and Commerce Corporation. Admiral Taylor was chief constructor of the United States Navy and chief of the Bureau of Construction and Repair until July 1, 1922, at which time he retired. Since then he has been engaged in claims board work which will be completed in time to take up his duties with the American Ship and Commerce Corporation, October 1. His headquarters for the time being will be in Washington. Rear Admiral Taylor is the author of a number of books on naval subjects and is recognized as the highest international authority on steam power and ship propulsion. He is the first American ever honored by the award of the gold medal of the British Institution of Naval Architects for the best original paper on ship-shaped stream forms. He was retained by the British Government as an expert in the famous case growing out of the collision of the *Olympic* and the *Hawke* in 1911.

Rear Admiral D. W. Taylor, U. S. N. (Retired)

A. P. Allen, manager of sales and repairs of the Federal Shipbuilding Company, with sales offices at 26 Beaver street, New York, has resigned from the Federal organization and will enter a manufacturing and sales business of his own, the nature of which has not as yet been made known. Mr. Allen has been with the Federal Shipbuilding Company, a subsidiary of the United States Steel Corporation, for over two years and has during this time built up an efficient sales organization. Previous to his connection with the Federal shipyard, he was chief engineer of the Pacific coast plants of the Bethlehem Shipbuilding Corporation and during the last part of the war he was stationed in Washington as chief engineer and assistant manager of the Department of Construction and Repair of the United States Shipping Board.

A. P. Allen

Elmer Schlesinger has resigned as general counsel of the United States Shipping Board, the resignation taking effect September 1. Mr. Schlesinger joined the Board in June, 1921, with the idea of spending a few months in organizing the legal department of the Shipping Board and the Emergency Fleet Corporation. His services, not only in organizing the law department, but in protecting the interests of the Government, particularly in the matter of the large number of undisposed claims pending against the Shipping Board at the time he commenced his work in the department, have been very valuable. Mr. Schlesinger will return to private practice at once as a member of the firm of Stanchfield and Levy of New York.

Sanford H. E. Freund and Chauncey G. Parker have been appointed as general counsel of the United States Shipping Board and the Emergency Fleet Corporation following the resignation of Elmer Schlesinger. Mr. Freund will have general supervision and control of the Admiralty division, the contract, opinions, recoveries and special assignment division of the Emergency Fleet Corporation and other legal matters of the United States Shipping Board besides claims and litigation. Mr. Freund has been special counsel with the Emergency Fleet Corporation. during the past year. He graduated from Harvard University in 1901 and from the Harvard Law School in 1903. His career from that time until 1910 was mainly devoted to lecturing at Boston Univerity Law School, University of Chicago Law School and at the Harvard Law School, at the same time practising law in the city of Boston. From this time until 1918 he was general attorney for various railway companies; from then until 1919 he served as director of the United States Employment Service and also as a member of the facilities division of the war industries Board. In 1919 and 1920 he was assistant general counsel of the United States railway administration in charge of financial affairs. He resigned from this position and practised law in New York until he became special counsel of the Emergency Fleet Corporation.

© Harris & Ewing

S. H. E. Freund

Chauncey G. Parker, before assuming his duties with Sanford H. E. Freund as general counsel of the United States Shipping Board, was special counsel with the Emergency Fleet Corporation during the past year. He will have control and direction of litigated cases throughout the United States and also supervision of claims presented to the United States Shipping Board. He graduated from Harvard University in 1885 and Columbia University in 1887; from 1888 until 1915 he practiced law in New Jersey, taking a prominent part in several of the leading litigated cases in that state; in 1915 he served as receiver to the International Mercantile Marine Company and the Rock Island Company; in 1918 he was made special legal expert with the War Risk Insurance Bureau, Washington.

Chauncey G. Parker

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Contract for Constructing Two Steamers to Cost $6,000,000 Awarded to Great Lakes Yard

THE contract for the construction of two passenger steamers to cost a total of approximately $6,000,000 has been awarded to the American Shipbuilding Corporation of Cleveland, O., by the Cleveland and Buffalo Transit Company, according to official announcement today.

The vessels will be of the paddle-wheel type driven by reciprocating engines and are to be 544 feet in length by 58 feet beam, which is a slight modification from the original intention, which is understood to have called for a vessel 600 feet long. The boats will have 600 cabins with accommodations for about 2,000 passengers each and were designed by Frank E. Kirby, naval architect at Cleveland and New York.

Two and a Half Million Dollar Contract for Four Diesel Electric Dredges Awarded to Sun Company

AT a price of $2,528,240, the Sun Shipbuilding Company, Chester, Pa., has been awarded the contract for the construction of four Diesel-electric, seagoing hopper dredges for the War Department, Washington, D. C. The Sun Company submitted the lowest tender out of a list of 16 bidders, including four navy yards.

The ships are to have an overall length of 268 feet 5 inches, each, length between perpendiculars 254 feet, beam molded 46 feet, depth 22 feet 6 inches, draft loaded 19 feet 6 inches and speed 11½ knots.

According to the specifications, each vessel will be equipped with three engines of the McIntosh Seymour type of 1,000 brake horsepower on the four-cycle system.

Steamer Caldas Awarded to Federal Yard for Overhaul

THE steamship *Caldas* of the Grace Line was awarded on September 13 to the Federal shipyard at Kearney, N. J., for general reconditioning of hull and engines including the alteration of bulkheads for fuel oil and miscellaneous repairs. The contract will cost about $35,000.

City of Norfolk to Spend $650,000 for Harbor Property

THE city of Norfolk, Va., will on October 1, 1922, make an extensive addition to its holdings of waterfront terminal property. The City Council has authorized the purchase of wharf, pier and warehouse property of the Old Dominion Steamship Company on Water street for $650,000. The purchase was recommended to the Council by City Manager Charles E. Ashburner, the property having a frontage of 650 feet on the water front.

Under the plan recommended by the city manager, the city is to issue $650,000 worth of 4½ percent fifty-year bonds.

Acceptance Trials of Submarine S-48 Prove Successful

UNITED STATES submarine *S*-48, built by the Lake Torpedo Boat Company, Bridgeport, Conn., successfully completed her official Government acceptance trials on Saturday, September 9. The trials were conducted under the supervision of a trial board consisting of Capt. J. G. Tawresy, Lieut. E. F. Zemke, Lieut. J. D. Jones, Lieut. Whitney and Messrs. Ford and Moore recorders.

The earlier trials consisted of surface and submerged firing of service torpedoes, one hour full speed submerged run, steering gear tests ahead and astern, quick reversing of engines, fuel economy tests, operating at various depths submerged and changing depths without change of trim, quick submergence from full power submerged under motors to a depth of 40 feet in 64 seconds. After the completion of these tests, a 52-hour endurance run was made, four hours of which was at full speed, 14½ knots, and the remainder of the time at 13¾ knots. This latter trial, considered the most severe test required to be carried out, was accomplished without a failure of any description. The engines, which are of the Busch-Sulzer type, and auxiliaries functioning perfectly.

The design and construction of this vessel has been stated frequently by naval officials to reflect great credit upon the builders and the boat is considered to be in advance of any submarine now in this or any other navy.

Charles Ward Engineering Works Awarded Contract for Construction of Sternwheel Lighthouse Tender

THE contract for the construction of the steel, stern wheel, steam-propelled lighthouse tender *Greenbrier* for the Lighthouse Service of the Department of Commerce, Washington, D. C., has been awarded to the Charles Ward Engineering Works, Charleston, W. Va., at a price of $128,000. The time of completion or delivery is 12 months. The bids submitted for the work were as follows:

Charles Ward Engineering Works, Charleston, W. Va.	$128,000
Howard Shipyard and Dock Company, Jeffersonville, Indiana	128,727
Johnson Iron Works, New Orleans, La.	159,800
Dubuque Boat and Boiler Works, Dubuque, Iowa	137,000
Charles Hegewald Company, New Albany, Ind.	169,000
Dravo Contracting Company, Pittsburgh, Pa.	169,800

The vessel will be for use in the upper Mississippi and Ohio rivers and will have a length overall of 164 feet 6 inches; length, molded, 140 feet; beam over guards, molded, 32 feet 6 inches; depth at side, molded, 5 feet; draft, light steaming condition, 2 feet 8 inches. The tender will have a complete steel hull braced by longitudinal and transverse bulkheads. The propelling machinery will consist of twin non-condensing steam engines direct connected to a radial stern wheel and supplied with steam by three horizontal underfired flue boilers. The vessel will be equipped with a hand steering gear and also a steam steering gear of the direct acting single cylinder type similar to the Crowley-Johnson or other approved make and sufficient capacity to operate the boat's three rudders.

An approved cast steel double barreled capstan, driven by a double cylinder steam engine in the forepeak, will also be supplied and there will be two metallic lifeboats about 15 feet long, fitted with air tanks, certified for 11 persons each, provided with solid round bar swinging davits; and a life raft of the catamaran type certified for not less than 8 persons. The boat will be heated throughout by steam.

The main engines will have cylinders 15 inches in diameter with a common stroke of 84 inches and all parts designed for a working pressure of 200 pounds.

Boilers

There will be 3 steam boilers of the Mississippi river type designed for a working pressure of 200 pounds per square inch. Each boiler will be about 26 feet long having two lap welded flues without joints.

The generating set will be mounted on a common sub-base of cast iron and be of a steam turbine direct driven type having a capacity of 10 kilowatts making approximately 3,600 revolutions per minute.

Orders for Three Additional Lake Freighters Expected

IT is reported on good authority that contracts will soon be placed on the Great Lakes for three additional freight steamships. Although definite details are not available at this time, the vessels will probably be about 600 feet long and have a deadweight carrying capacity of approximately 12,000 tons. The total cost of the three vessels will probably be close to $2,500,000 and it is expected that the orders will be placed before the end of this month.

Supply Vessel for Commercial Pacific Cable Co. to Be Built by Sun Shipbuilding Company

THE supply ship for the Commercial Pacific Cable Company which has been designed by Cox & Stevens, naval architects, 25 Broadway, New York City, has been awarded to the Sun Shipbuilding Company, Chester, Pa.

This vessel, which has a length of 169 feet 6 inches between perpendiculars, 30 feet beam and 15 feet depth, is equipped with triple expansion engines having cylinder diameters of 17 inches, 25 inches and 42 inches with a 30-inch stroke. Steam is to be generated in two Scotch boilers fitted with Dahl oil burners.

The cost of the vessel could not be learned but it is understood that it was close to $1,000,000. The contract calls for the completion of the ship in March, 1923.

Duluth Shipyard Is Awarded Contract for the Construction of Government Derrick Scow

THE Marine Iron & Shipbuilding Company, of Duluth, Minn., which submitted the lowest bid to the United States Engineer office at Duluth for the construction and delivery of a steel derrick scow, complete with machinery and equipment, has been awarded this contract. The scow is to have an over all length of 147 feet 4 inches, a beam molded of 40 feet and a capacity of 715 long tons.

The Marine Iron & Shipbuilding Company submitted bids on two propositions, as follows: (A) to construct the derrick scow complete, as specified, and to make provisional delivery afloat at the builders' yard—$97,844.22; and (B) to construct the derrick scow from contractor's own designs, weights and specifications, complete with steel hull, derrick, houses, living quarters, and stock machinery and equipment, in acordance with Government plans and specifications—$93.220.22.

Bids October 10 On Diesel Electric Tug for Mobile

BIDS for the construction of a 100-foot Diesel electric towboat for the United States Engineer Office, Mobile, Ala., will be received at Mobile until 11 A. M. October 10, 1922, according to latest announcements. The proposed vessel will have a length overall of 119 feet 3⅝ inches; length, molded, 100 feet; breadth, molded, 23 feet; depth, 5 feet; draft, loaded, 3 feet. The vessel and equipment will be built to the American Bureau of Shipping rules.

The vessel will be heated throughout by a hot water heating system and an Ideal-Arcola heater or equal of suitable size fitted for burning oil, if practicable, otherwise for coal, will be installed in the generator room. A motor-driven capstan will be installed, the capstan having a 9-inch barrel and will be about 32 inches high capable of pulling 6,000 pounds at 15 feet per minute. The motor will be of the inclosed ventilated type of at least 5 horsepower.

Machinery

The two Diesel engines will be a standard commercial product of American manufacture. At least two of the engines of the size offered shall have been under successful operation for at least one year on the date of opening bids and shall be under successful operation on that date, the bidders to furnish name of motors, location of engines, purpose for which used and length of time in actual operation.

Main Generating Sets

There shall be installed two multiple cylinder two- or 4-stroke cycle fuel Diesel engines, each capable of developing sufficient power to produce an output of at least 100 kilowatts. Each engine will be direct connected to an open type, direct current, continuous rating generator with a capacity of at least 90 kilowatts and with a 10 kilowatt exciter direct connected on main shaft.

Other Equipment

The main generators shall be shunt wound separate excited open type and of at least 90 kilowatts capacity at 125 volts D. C. The exciters shall be compound wound open type of at least 10 kilowatts capacity at 125 volts D. C.

The propelling motor shall be shunt wound separately excited open type and be at least 200 horsepower at 240 volts, 600 revolutions per minute.

A 7½ kilowatt 125-volt direct current generator direct connected to a gasolene engine on the same bedplate will be installed in the engine room. The engine shall be a four-stroke cycle 4 or 6 cylinder type with forced lubrication, cylinders and oil cooler water cooled, magneto ignition and complete with all necessary equipment.

Twenty-Six Additional Contracts Placed By Newport News Yard for Reconditioning Steamship Leviathan

TWENTY-SIX additional contracts for material to be used in the reconditioning of the steamship *Leviathan*, the world's greatest ship conversion job, have been placed by the Newport News Shipbuilding & Dry Dock Company, Newport News, Va., according to latest official announcement. A wide variety of material is covered in the new contracts. The list of supplies and the manufacturer are as follows:

MATERIAL	MANUFACTURER
Door Switches for Wardrobes	Woodhouse Electric Co.
Wire for Floor Outlets	Hazzard Mfg. Co.
Asbestos Millboard for Radiators	Ehret Magnesia Co.
Radiator Valves for Heating System	McNab & Harlin Mfg. Co.
Slate Panel for Switchboard No. 2	Portland Monson Slate Co.
Vises for Carpenters and Plumber Shops	Southern Supply Company
Manila Rope for Running Rigging	Columbian Rope Co.
Carbon Brushes	Morganite Brush Co.
Brass Gasket Rings for Ozone Gen. Tubes	W. L. Woodside Co.
Plastic Fire Brick	Jointless Firebrick Co.
Fire Screen Bulkhead at Frame No. 155	Coburn Trolley Track Mfg. Co.
Injectors for Donkey Boiler	Hayden & Derby Mfg. Co.
Pax-Tite Leather Packing for Telemotor Pistons	Watson Stillman Co.
Armature Coils for Ventilation Fan Motor No. 173	Standard Electrical Mfg. Co.
Flexible Metallic Steam Hose	The American Metal Hose Co.
Recording Electric Pyrometers	The Bristol Company
Olomel Tester Putty	Olomel Mfg. Co.
Lacquer Screens for 1st class Social Hall	Robt. W. Chanler
Indicating Thermometers for F. O. Tanks	Schaefer & Budenberg Mfg. Co.
Sight Flow Indicators for Lubricating Oil System	S. F. Bowser & Co.
Leather Packing for Change Valves	The Watson Stillman Co.
Receptacles for Outside Deck Fixtures	Oceanic Electrical Supply Co.
Steam Traps for Sanitary System	Strong Carlisle & Hamond Co.
Copper Smith Work on Copper Coil Radiators	R. A. Burroughs & Co.
Thermometers for Forced Lubrication	Schaefer & Budenberg Mfg. Co.

P. & R. Railroad May Build New Docks in Cape May Harbor, N. J.

Following the start of the work of deepening the entrance to Cold Spring inlet, which leads into Cape May harbor, N. J., by the dredge *Absecom*, announcement is made that the Philadelphia and Reading railroad intends to build docks on the north side of the harbor.

Conversion of Four Steamers Awarded Todd Shipyards

THE contract for the conversion of four ships of the Southern Pacific Steamship Company from coal to oil burning vessels has been awarded to the Todd Shipyards Corporation, at a total cost said to be $336,800. The ships involved are the *El Siglo* and *El Cid*, which went to the Robins Yard, Brooklyn, N. Y., and the *El Dia* and *El Rio*, which have been placed at the Tietjen & Lang plant, Hoboken, N. J.

The bids submitted for the conversion and work incidental thereto are understood to have been as follows:

Tietjen & Lang	$336,800
W. & A. Fletcher	348,000
Robins D. D. & R. Co.	360,800
Morse D. D. & R. Co.	400,000

Shipbuilding In America Shows a Favorable Advance

There were under construction in American shipyards on September 1 a total of 25 seagoing steamers of 156,530 gross tons and 75 steel river and harbor boats of 37,395 gross tons, according to figures compiled by the American Bureau of Shipping. This shows an increase of 9 ships and 40,000 gross tons over July 1.

Since September 1, contracts for eight new ships are known to have been placed in American yards.

The work in progress on new steel tonnage on September 1 is shown in the following table:

All-Steel Vessels

Yard	No.	Gross.
American Shipbuilding Co.	4	33,100
Bethlehem Shipbuilding Co.—		
Sparrow's Point	3	15,900
Alameda Plant	3	28,500
Federal Shipbuilding Co.	3	16,000
Great Lakes Engineering Works	1	6,585
Manitowoc Shipbuilding Co.	1	4,900
Newport News Shipbuilding Co.	3	11,125
New York Shipbuilding Corp.	2	13,600
Pusey & Jones	2	5,240
Sun Shipbuilding Co.	2	13,004
Toledo Shipbuilding Co.	1	8,400
Total	25	156,530

River and Harbor Boats

River and harbor steel tonnage building and contracted for in the United States for private owners September 1:

Yard	No.	Gross.
American Bridge Co.	18	4,900
American Car & Foundry	3	1,500
Bethlehem Shipbuilding Corp.		
Baltimore D. D.	3	2,100
Alameda Plant	2	2,400
Consolidated Shipbuilding Corp.	2	500
Doullut & Williams	1	450
Dravo Contracting Co.	15	4,930
Eichlacy, John, Jr.	1	65
Federal Shipbuilding Co.	3	2,850
Johnson Iron Works	1	250
Kyle & Purdy	1	300
Los Angeles Shipbuilding and Drydock Co.	2	2,400
Marietta Manufacturing Co.	1	250
Midland Barge Co.	4	2,300
Pusey & Jones	1	300
Riter-Conley Manufacturing Co.	5	2,150
Staten Island Shipbuilding Co.	4	5,150
Tebo Yacht Basin	3	450
Ward Eng., Charles	2	2,000
William Cramp & Sons	3	2,100
Total	75	37,395

Midland Barge Company Has Low Bid of $59,850 for Two 4,000-Barrel Steel Oil Barges

THE bid of $59,850, for the construction and delivery of two 4,000-barrel steel oil barges for the Mississippi River, submitted by the Midland Barge Company, of Midland, Pa., has been recommended for approval by the U. S. Engineer Office, at New Orleans, La.

Tenders were submitted on September 15 with the following results:

Midland Barge Company	$59,850
Charles Ward Engineering Works	71,750
Penn Bridge Company	74,250
Dravo Contracting Company	79,550
Nashville Bridge Company	86,940
Tampa Shipbuilding and Engineering Company	96,000
Johnson Iron Works Dry Dock & Shipbuilding Company	85,275
American Bridge Company	104,500

The barges will have a length molded of 120 feet, beam molded 36 feet, depth molded 7 feet 6 inches.

Charles Ward Engineering Works Is Low Bidder for Construction of Two Steel Barges for Alabama

THE Charles Ward Engineering Works, of Charleston, West Virginia, with a price of $17,000, submitted the lowest tender for the construction of two steel barges for the United States District Engineer Office, at Florence, Ala., for which bids were opened on September 18. The proposals, which have been submitted to the Chief of Engineers at Washington for approval and award, were as follows:

Charles Ward Engineering Works	$17,000
Midland Barge Company	17,800
Nashville Bridge Company	19,240
Penn Bridge Company	19,340
Dravo Contracting Company	20,870
American Bridge Company	21,750
Howard Shipyards & Dock Company	22,773
Virginia Bridge & Iron Company	23,895
Charles Hegewald Company	24,490
Johnson Iron Works Dry Dock & Shipbuilding Company	26,900

Jahncke Dry Dock Company of New Orleans Busy with Newest Reconditioning Contract Awards

THE Jahncke Dry Dock Company, of New Orleans, La., has been awarded the contract to recondition the U. S. Engineer Department dredge *Galveston.* The work includes the general overhauling of all machinery and will cost about $50,000.

The Jahncke Company has also been awarded the contract to paint forty of the Mississippi Warrior steel barges, type C-500, this work to be done while the barges are making their usual trips up and down the Mississippi River. The company has converted a wooden barge of their own into a houseboat for store rooms and living quarters for the men on the above work. The contract involves about $75,000. The yard will also drydock the Sinclair Navigation Company's tanker *Tamesi* for a general overhauling.

$24,870 Bid By Nashville Bridge Co. for Dredge Pipe

BIDS for thirty 40-foot lengths of 20-inch discharge pipe, one 90 degree 20-inch elbow and four 3-foot lengths of 20-inch pipe for United States hydraulic pipe line dredge *Wahalak*, were opened by U. S. Engineer Office, at Mobile, Ala., on September 5. The Nashville Bridge Company, of Nashville, Tenn., with a figure of $24,870, submitted the lowest total price.

Sun Yard to Build Three Barges for Pennsylvania R. R.

IN addition to the contract announced recently, which was awarded by the Pennsylvania Railroad Company to Pusey & Jones Shipbuilding Company, Wilmington, Del., for the construction of a steel floating grain elevator, 100 feet long, a contract has been awarded by the same company to the Sun Shipbuilding Company, Chester, Pa., for the construction of three barges, each with a capacity of between 40,000 to 50,000 bushels.

The floating grain elevator will be capable of delivering from 12,000 to 15,000 bushels an hour and will be equipped with special machinery built by the Webster Manufacturing Company, of Chicago, Ill.

Million Dollar Port Improvement for Pearl Harbor

THE Bureau of Yards and Docks, Navy Department, Washington, D. C., has received bids under specification 4501 for clay walls and pier at the naval operating base, Pearl Harbor, H. T., as follows:

For the work complete, from the Hawaiian Dredging Company, 854 Kaumana street, Honolulu, (1) $1,000,000 (450 days); (5a) add $23,000, deduct $21,000; (7) add $5, deduct $3; (8) add $1.50, deduct $1.00; (10) 90 cents telegraphic modification; (1) deduct $188,257; (5) deduct $4,715 add $6,-396.

J. Lloyd, McKansas Building, Honolulu, (1) $1,105,736 (450 days); (2) $1,200,860 (450 days); (3) $785,000.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Additional Contract, Savannah, Ga.—Coast Guard cutter Yamacraw also went to Wilkinson Company's shops to undergo repairs.

Steam Pump Repaired, Buffalo, N. Y.—Steamer City of Buffalo was at Buffalo drydock to have one of her steam pumps repaired.

Lighter Repairs, Savannah, Ga.—A government derrick lighter went on Wilkinson marine railway to undergo repairs to the hull.

Schooner Drydocked, Portland, Ore.—The schooner Dauntless was lifted on the Port of Portland drydock for cleaning and painting the hull.

Dredge Drydocked, Chester, Pa.—The War Department's dredge Delaware was drydocked at the Sun Shipyard for miscellaneous repairs and painting.

Steamer Inspection, Long Island, N. Y.—Steamer Medon went to Hunter's Point drydock to be inspected by representatives of the Alaska Steamship Company.

Freighter to Be Repaired, San Francisco, Cal.—The Mary Hanlon went to San Francisco for repairs to her bow, stove in as a result of a collision with an oil tanker.

Conversion to Oil Burner, San Francisco, Cal.—A. R. Wood Lumber Company secured the Lake Bridge from the Shipping Board and re-converted her to burn oil.

Steamer at Southern Yard.—Steamer Cockaponset, assigned to Lykes Brothers for the London and Hull berth, moved from Nine-Mile Point to be drydocked for repairs.

Italian Steamer Drydocked, Chester, Pa.—The Italian steamer Teti was towed to the Sun Shipbuilding yards, where she was placed in drydock for miscellaneous repairs.

Boilers, Etc., Installed, San Francisco, Cal.—Steam schooner Brunswick went to the Eureka Boiler Works to have a new thirty-foot smoke stack and donkey boiler installed.

Propeller Blade for Steamer, Maryland.—The British Steamship North Pacific was docked at Sparrows Point for replacement of a broken propeller blade and to have her hull painted.

Conversion to Oil Burning System, Savannah, Ga.—United States dredges Morgan, Savannah and Gilmer went to Wilkinson Dry Dock Company to be converted to the White oil burning system.

Schooner Overhauled, Seaford, Del.—The Cumberland Queen, one of the largest four-masted schooners ever seen on the Nanticoke River, went on the ways at Seaford for complete overhauling.

Repairs to U. S. S. Eagle 34, San Francisco, Cal.—The U. S. S. Eagle 34 was towed into San Francisco bay with a broken planetary reduction gear. The vessel was taken to Mare Island for repairs.

West Coast Repairs.—At the Potero Plant of the Bethlehem Shipbuilding Corporation the company drydocked the Japanese freighter Ginyo Maru for temporary repairs. Price $25,000; time 12 days.

Baltimore Plant Contracts, Baltimore, Md.—The Baltimore Drydocks Plant of the Bethlehem Shipbuilding Corporation has received contracts for overhauling the Robin Hood and repairing the Nelson.

Vessel Repairs, San Francisco.—The South Coast went to San Francisco to be repaired, her mast and cargo booms missing and pilot house stove in as result of accident while unloading at Los Angeles.

New Ferry Ordered, Detroit, Mich.—Great Lakes Engineering Works were awarded contract to build a ferry steamer for the Detroit-Walkerville route. She will have a capacity for forty-five automobiles and 2,000 passengers.

Contract Award, Jeffersonville, Ind.—The Howard Shipyards is reported as having received a contract to construct a packet boat for the Eagle Packet Company, of St. Louis. The vessel will be 225 feet long and 50 feet wide.

Repairs, West Coast.—Steamer San Pedro, steam schooner Washington and lumber carrier Wahkeena went to the Bethlehem yards to be drydocked for cleaning. The dreadnaughts Oklahoma and Pennsylvania went to Hunter's Point.

Construction of Diesel-Electric Dredges, Chester, Pa.—Sun Shipbuilding Company was awarded the contract for the construction of four Diesel-electric, seagoing hopper dredges for the War Department, Washington, D. C. Price $2,528,240.

Contract Awarded, Cleveland, O.—The contract for the construction of two passenger steamers to cost a total of $6,000,000 was awarded to American Shipbuilding Corporation of Cleveland, O., by the Cleveland and Buffalo Transit Company.

Cleaning and Painting Contracts, California.—Southern Pacific ferryboat Santa Clara went on drydock to undergo cleaning and painting, and the Union Oil Company's carrier Oleum went on the Moore ways to also be cleaned and painted.

Sun Yard to Build Barges, Chester, Pa.—A contract was awarded to the Sun Shipbuilding Company by the Pennsylvania Railroad Company for the construction of three barges, each with a capacity of between 40,000 to 50,000 bushels.

Tug Completed, Milford, Del.—The Vineyard Shipbuilding Company completed a 60-foot wooden tug for the Munson Line, to be used in Cuban waters. The vessel will be propelled by a 100-horsepower Fairbanks-Morse surface ignition oil engine.

Bethlehem Plant Awarded Contract, Cal.—Bethlehem Shipbuilding Corporation, Union Plant, was awarded contract to install feed water heater, new feed pumps and new evaporators on the United States army transport President Grant. Price $22,000.

Contract for Freighter, Staten Island, N. Y.—The contract for the new steel freighter for the Catskill Evening Line was awarded to the Staten Island Shipbuilding Company. Price $101,260. Contract covered construction of hull, machinery foundations only.

Bethlehem Yard to Build Float, Baltimore, Md.—The sparrows Point Plant of the Bethlehem Shipbuilding Corporation was awarded contract for the construction of a car float for the Baltimore & Ohio Railroad, 283 feet long, 37 feet beam, and 10 feet 6 inches depth.

Canadian Commander Repairs.—The steamship Canadian Commander, which recently ran ashore at Plate Point, Little Miquelon, is at the Canadian Tankers' yard, Montreal, undergoing repairs which will cost close to $100,000. The ship sustained considerable hull damage.

Repairs, Pittsburgh, Pa.—Landing boat of Second Pool Coal Company, Allegheny River, was placed on ways of the Pittsburgh Dock Company for general overhauling. Two barges of the Equitable Towing and Transportation Company also went on the ways to be repaired.

Installation of Watertube Boilers, New York.—The New England Steamship Company, New York, placed an order with Babcock & Wilcox Company, 85 Liberty street, New York, for eight marine watertube boilers, aggregating 9,000-horsepower, for installation on Fall River liner Priscilla.

Special Type Ship Ordered, London, England.—The firm of Workman, Clark and Company, Ltd., is reported as having secured an order for the construction of a coal carrier of 10,000 deadweight tons of special type for an American firm. The new ship will be about 425 feet in length.

Steamboats Repairing, Great Lakes Section.—Steamer Samuel Mitchell went to Ecorse yards to have her engine rebuilt. Steamer Douglas Houghton was placed in drydock at Lorain for repairs to her wheel and rudder, and steamer Robert Fulton went to Cleveland for minor repairs, as a result of a collision.

Tanker Alameda Reconditioned, Philadelphia, Pa.—The former United States Navy tanker Alameda, which was beached near Cape Fear last winter, is said to have been purchased by the William Cramp Ship and Engine Building Company, which is planning to recondition her and offer her at a competitive sale.

Repair Work, Mobile, Ala.—Alabama Dry Dock & Shipbuilding Company made following repairs to steamship Federal: removed entire turbine, gears, etc., and replaced same; installed new lubricating system; made and installed with necessary piping to accommodate the oil system, and changed from forced feed to sight gravity system.

Construction of Motor Passenger Launch, Stamford, Conn.—The Luders Marine Company was awarded a contract for constructing fast motor passenger launch, 40 feet long, 9 feet beam, 5 feet 6 inches depth, and 3 feet draft, by the Standard Oil Company of New Jersey for the account of the Standard Oil Company of Venezuela.

Shipyard Activities, Mobile, Ala.—Mexican tug El Aguila went to plant of the Alabama Dry Dock and Shipbuilding Company for repairs. Considerable work was done on tug's plates, tailshaft, etc. Other vessels repaired at the same yard included the barges Coastwise, Oriole and Choctaw, the tug Hukey and the Coast Guard cutter Arrow.

Sub-Chasers Converted, New York.—Seabury & de Zafra, Inc., naval architects, 150 Nassau street, were awarded following contracts: Completion of engine trials of sub-chaser; prepare plans for conversion of another for yacht service, and a third for commercial use of fur interests; fit out E. S. Pawnee for wrecking and lighterage operations along Atlantic Coast.

Ferryboat for San Francisco, Cal.—Aven J. Hanford, president and general manager of the Golden Gate Ferry Company, has announced that a second steamer to engage in the service now maintained by the ferryboat Golden Gate between San Francisco and Sausalito is under construction. The vessel is to be named the Golden West and will be of the same type as the Golden Gate.

Installation of Boilers, Pittsburgh, Pa.—The Pearson Manufacturing Company received the contract to install a battery of three boilers on steamer National of the J. K. Davison & Brothers. They will be of the two-flue type, 38 inches wide and 26 feet long. The company also completed repairs to the boilers and machinery of the steamer Hibernia, owned by the Equitable Towing and Transportation Company.

Construction of Two Passenger Steamers, Wilmington, Del.—Contract for construction of two day-passenger steamers, driven by reciprocating engines, at total cost of $529,000, was awarded by the Wilson Line, of Wilmington and Philadelphia, to the Pusey and Jones Company of Wilmington, Del. Vessels designed by George G. Sharp Company, naval architects and consulting engineers, 30 Church street, New York City.

Repairs to Six Ships of San Francisco Corporation.—Six ships of the Pacific Freighters' Corporation were awarded to the following companies: Pequot Casco and Arcadia, Robins Dry Dock & Repair Company, Brooklyn, N. Y.; the Pawnee, Sun Shipbuilding Company, Chester, Pa.; the Isonomia and Ida, Maryland Dry Docks, Baltimore, Md. Repairs included drydocking, scraping, painting, boiler work and general overhauling subject to inspection.

Spanish Naval Orders.—According to accounts from London, a contract has been arranged between the Spanish government and the Sociedad Espanola de Construccion Naval covering a period of three and a half years and providing for the construction of two large and powerful cruisers, together with destroyers, gunboats and submarines. It was stated that the cruisers will be of the Raleigh type, heavily armored, with powerful guns and that the armament will be supplied by Messrs. Vickers, Limited, and the armor plates by Messrs. William Beardmore and Company, Ltd.

SHIPYARDS AND DRY DOCKS

Establish Wood Yard, New Orleans, La.—A shipyard, for building and repairing small wooden boats, is to be established on the Jefferson Terrace Subdivision above the Jefferson Race Track by Paul and Fred Zibilich.

Shipyards to Be Moved, West Coast.—Al Larsen's Boatbuilding Plant, the Wilmington Boat Works and the M. and M. Machine Shop will be forced to move from Mormon Island, near Los Angeles, Cal., because of contemplated improvements by the city of Los Angeles.

10,000-Ton Drydock Reaches Mobile.—The last of four sections of the 10,000-ton drydock being moved to Mobile from New York by the Todd Shipyards Corporation has arrived at its destination. The 1,700-mile journey was made in sixty-eight days, in spite of unfavorable weather and adverse winds. All four sections arrived in perfect condition and will be reassembled immediately for operation late this month.

Navy Yard to Close, Charleston, S. C.—November 1 will mark the date of the closing of the Charleston Navy Yard. It had been expected that the yard would be closed about September 1, orders having been issued that it should be closed as soon as possible, but owing to the unemployment at Charleston, Acting Secretary Roosevelt decided to defer the closing and provide for the gradual discharge of the employees.

New Section Added to Drydock, New Orleans, La.—A new 5,000-ton section is being added to the present 2,000-ton drydock of the Johnson Iron Works Dry Docks and Shipbuilding Company. This will increase the efficiency of the plant and at the same time enable it to accommodate the largest vessels that enter the port of New Orleans. The section, constructed in New York, represents an outlay of $100,000, and was towed to New Orleans from the building point. Nearly 500,000 feet of lumber were used in the construction of the section. The new dock will accommodate vessels drawing 21 feet of water and will be operated by electricity. About twenty vessels a month are handled by the concern.

PORT IMPROVEMENTS

Pier Extension, San Francisco, Calif.—State Board of Harbor Commissioners, Calif., awarded contract to Clinton Construction Company for extending Pier 22. Price $76,365.

Pier Contract, Philadelphia, Pa.—Simpson, Brown & Company, 90 West street, New York, were awarded contract by F. H. Caven, Director of Public Works, Philadelphia, for one story pier building, Allegheny Avenue and Delaware River and also for improving and enlarging Allegheny Wharf 127. Engineer's estimate, $100,000.

Pier Extension, San Francisco, Cal.—The Clinton Construction Company was awarded the contract for extending Pier 44 to meet the requirements of the China Mail Steamship Company, to whom that section of the waterfront docking space had been awarded, by the State Board of Harbor Commissioners. The Clinton Company, with a price of $57,425, was the lowest bidder of five, the highest being Hannah Brothers, who asked $62,350 for the work.

Contract Let, Orange, Tex.—Contract for construction of additional units to the municipal wharves was awarded by wharf and dock commission to Houston Construction Company. Improvements are to cost approximately $221,000. Contract provides for the extension of the wharf apron for a distance of 1,008 feet; construction of two roofed sheds, dimensions of each being 400 by 90 feet; the extension of the municipal railway tracks behind the new warehouses for a distance of about 1,000 feet and construction of 100 feet of open platform between the two houses. A brick fire wall will separate the two sheds. Contract provides that work shall begin at once and shall be completed within 150 days from date of beginning. Wharf and dock construction contract will be carried out under a bond issue for $250,000, suspended for 1921 and put into effect in 1922.

GOVERNMENT WORK

Riprapping Dike, Mare Island, Cal.—Specification 4,700. Bureau of Yards and Docks, Navy Department, Washington, D. C., plans riprapping dike.

Riprap Protection, Hampton Roads, Va.—Specification 4,699. Bureau of Yards and Docks, Navy Department, Washington, D. C., plans riprap protection for north breakwater at Hampton Roads.

Steel Hull, Montgomery, Ala.—Johnson Iron Works Dry Dock & Shipbuilding Corporation, Morgan and Seguin streets, has received a contract from U. S. Engineer, Montgomery, for a steel hull for dipper dredge Upatoi. Price $25,850.

FOREIGN ACTIVITIES

Larache Harbor Developments, Morocco.—A sum of 3,461,000 pesetas for Larache Harbor Works is included in a supplementary credit of about sixty million pesetas for public works in the Spanish zone of Morocco, laid before the Spanish Parliament by the Minister of Finance.

Floating Dock, Trieste.—A floating dock of reinforced concrete construction, 64.15 metres long and 21 metres wide, has been recently acquired by the Navigation Company of Trieste. The dock has electrically driven centrifugal pumps installed and has a lifting capacity of 2,000 tons. It has been built for the repair of vessels on the Adriatic fleet of the company.

Launching of Steamer, Scotland.—The steamer Spero was launched by the Dundee Shipping Company. The company built the vessel for Ellerman Wilson Line of Hull. The dimensions of the Spero are as follows: Length, 257 feet; breadth, 37 feet; and depth molded, 19 feet. The new ship, which will be engaged in the produce trade between Denmark and Great Britain, will be fitted with refrigerating machinery.

Trials of Passenger and Mail Steamer, Scotland.—The Scott's Shipbuilding and Engineering Company, Greenock, completed and handed over the twin-screw passenger and mail steamer Aconcagua, built for the Compania Sud Americana de Vapores, of Valparaiso. The vessel is one of two sister ships, the second to be launched later. The Aconcagua ran trials on the Firth of Clyde and attained a mean speed of 17½ knots—half a knot over that stipulated in the contract, all machinery working with great smoothness. The two vessels are each 438 feet in length over all, 56 feet molded breadth, 33 feet depth molded to bulkhead deck, of 7,000 tons gross, and of 8,500 shaft horsepower.

Maiden Voyage of Canadian Pacific Steamer.—The new steamship Montclare, the third new "M" steamship of the Canadian Pacific Line, completed her maiden voyage to Montreal successfully. She was launched on December 17, 1921, at the yards of John Brown & Company, at Clydebank, Scotland. The Montclare, built to the requirements of the highest class of Lloyd's Register under special survey, is classed "100A1," and is a geared-turbine steel steamship with two funnels. The vessel is 566 feet long, 70 feet in breadth, 51 feet depth; over 16,418 tons, with regular speed of 17 knots. Accommodation is provided for not less than 620 cabin passengers, and 1,550 third class passengers. She burns oil for fuel.

Oil Tank Steamer Launched, Newcastle-on-Tyne.—Swan, Hunter & Wigham Richardson, Ltd., from their Neptune Shipyard, launched a large oil tank steamer, being built to the order of the British Tanker Company, Ltd. The steamer, which is designed to carry over 10,000 tons of oil, is about 455 feet in length by 57 feet beam, and is being constructed to attain the highest class in Lloyd's Register. The propelling machinery will consist of a set of turbines of the Metropolitan-Vickers Rateau type, with double reduction gearing of the three-box, floating frame type, steam being supplied by three large boilers fitted with Howden's system of forced draft, and burning oil fuel on the Wallsend-Howden system. The principal engine-room auxiliaries will be electrically driven. The vessel was named the British Gunner.

Oil Tanker Launched, Scotland.—Messrs. William Beardmore & Company, Ltd., launched from the East Yard of their Naval Construction Works, Dalmuir, the oil tanker British Merchant, to the order of the British Tanker Company, Ltd. The vessel is built of steel under special survey to class 100A1 at Lloyd's and is framed throughout on the Transverse System. She has a length between perpendiculars of 440 feet, breadth 57 feet, depth molded 33 feet 11 inches, 26 feet 6 inches draft, and is of 10,000 tons deadweight with a speed of 11½ knots. Her oil carrying capacity is about 9,500 tons of light oil in twenty compartments carried up to the main deck, with expansion trunks to the upper deck and side tanks between the main and upper decks. Steering gear is electrically driven, all other auxiliary machinery being steam-driven. Propelling machinery consists of one set of compound turbines of Metropolitan-Vickers type driving double-reduction gearing, and steam is supplied by three single-ended cylindrical boilers.

Chilean Ports to Be Improved.—A German engineering firm has been awarded a contract for erecting a modern pier, etc., at Valparaiso. All material for the pier, which will be constructed of cement and steel, are also to be obtained from Germany. The contract calls for an irregular triangle extending into the sea, its base formed by the shore line, and its sides by two massive stone walls, which, starting at the base, will converge in the waters of the harbor. This triangle will cover an area of 17,280 square metres, while the wall will have a length of 199 metres on the west side and 135 metres on the north side of the triangle. Extending toward the west, in continuation of the north sea-wall, the pier proper will be constructed of re-inforced concrete. The length will be 162 metres, and the width eighteen metres at the starting point, diminishing to 16.8 metres at the extreme end. Loading and unloading equipment is not included in the contract, the placing of this contract being in the hands of the Railway Department, Santiago-de-Chile, which has now complete control of the Arica-La Paz Railway. The equipment will consist of one 25-ton, two 3-ton and two 5-ton electric cranes, and two special chutes for loading ore into lighters will be required. The construction price of the pier and attendant works is 3,050,000 pesos (paper), plus 200,000 pesos (gold), of 18d. The work is expected to occupy at least two years. Besides improvements at Valparaiso, complementary works at the port of Antofagasta and repair works at the ports of Constitucion, Iquique, Talcahuano, Lebu, Puerto, Saavedra and Valdivia will be carried out.

Danzig's Shipyards Internationalized.—Danzig's shipyards and railway shops, in the past operated by the City Government, are to be "internationalized." The Danziger Werft (Danzig Shipbuilding Yards) and the railway shops are employing about 5,000 men at the present time on repair work largely, but the building of five steamers for Chile has begun. The repair shops were the property of the German Government before Danzig became a free city. The committee appointed some months ago by the Senate of the Free City of Danzig to formulate plans for operation of these properties has just submitted its report to the Senate. The adoption of the plan recommended by the committee is not absolutely certain, although as about eight months have been spent in perfecting the project it seems highly probable that the scheme will be carried through. According to the plan, both the shipyards and the railway shops are to be "internationalized," each being converted into a stock company conducted independently of the other, although having community of interest. The capital of each company is to be 20,000,000 German paper marks; the stock to be taken by four groups—the first, the French company, Societe des Betignolles of Paris; the second, the English company, Cravens & Company, Ltd., of Sheffield; the third, a group of eight Warsaw banks, and the fourth, not yet formed, a group of Danzig banks and capitalists. Danzig and Polish interests are each to have 20 per cent of the capital stock in each of the companies; in the shipyards company the English group is to have 60 per cent, and the French company is to have 60 per cent of the railway shops' stock. The title to the property, grounds, buildings and equipment is to rest in common with Danzig and Poland.

Todd Yard Holds Successful Tests of New Equipment on Fireboat

The official tests of the New York City fireboat *James Duane*, held at the Clinton plant of the Todd Shipyards Corporation, proved highly successful and indicated that she will be the most efficient fire fighter afloat. New turbines and pumps were inspected at the plant by the Fire Commissioner, Thomas Drennan, and other officials from the Fire Department and the National Board of Underwriters.

The new pumps are Lea-Courtney centrifugal, single stage double suction, driven by Westinghouse steam turbines. Against a pressure of 150 pounds, the pumps discharged 9,800 gallons of water per minute; against a pressure of 175 pounds, the pumps delivered 7,900 gallons per minute; against a pressure of 300 pounds, the pumps delivered 4,850 gallons of water per minute.

STEAMSHIP INTERESTS

The Rutland Railroad, which disposed of its lake steamers when the provisions of the Panama Canal law went into effect, has announced a resumption of rail and lake freight transportation between New England and the West via Ogdensburg, N. Y.

Blakely Smith & Company, of Houston, Texas, local agent for the Nervion Line, has announced the extension of its service to include direct sailings from Houston to Genoa, Italy. The Houston-Barcelona service of the line will be maintained as usual. The first ship of the new service is due in Houston about October 1. Sailings at monthly intervals will be maintained. Although all cargo offered will be accepted, it is thought that a large portion of the shipments will consist of cotton. Large shipments of cotton are expected to move through Houston to Genoa this season.

Saturday, August 19, was the second anniversary of the first sailing of the United American Line from New York. Since August 18, 1920, the United American Lines has had a total of 436 sailings of American flag ships from United States North American ports.

The steamer *Santa Ana* will be added to the fleet of the Grace Line operating between New York and ports of the West Coast. Sailings from September 7 will be fortnightly instead of every three weeks as heretofore. The combination cargo and passenger vessels now operated in the service by the Grace Lines are the *Santa Louisa, Santa Elisa* and the *Santa Teresa*. Each has accommodations for about 100 passengers. Ports of call in Chile and Peru are Callao, Mollendo, Arica, Iquique, Antafagasta, Valparaiso and Tulcuano.

According to announcement by Walker-Ross, Inc., the Tatsuuma Kisen Kaisha has inaugurated a transpacific service between the Pacific Northwest and the Orient. The first steamship in this service is the *Somedono Maru*, which will go on berth in Puget Sound during the last half of September, loading for Japanese ports. A monthly service will be maintained from Puget Sound and British Columbia ports, and also from Columbia River and Grays Harbor if inducements are sufficient.

The Danish East Asiatic Company is to re-establish offices in Seattle and will in the future maintain regular service out of that port for the first time since the beginning of the World War in 1914.

TRADE PUBLICATIONS

Galvanizing Equipment.—Apparatus of the moving cathode type for galvanizing and plating has been developed by the U. S. Galvanizing and Plating Equipment Company, 32 Stockton street, Brooklyn, N. Y. The arrangement of the apparatus, its value in a variety of plating work, together with numerous illustrations and diagrams, make up the pamphlet. Contained in the same covers is also a pamphlet on U. S. automatic cleaning, pickling, acid dip, neutralizing, rinsing, drying and allied equipment.

Stokers.—Bulletin 294 has been issued by the B. F. Sturtevant Company of Boston, Mass., describing the Sturtevant underfeed stokers, which include a centrally located horizontal retort, extending longitudinally with the furnace and provided at its upper edge with tuyeres through which air is introduced to the fuel as it rises into the fire. A complete explanation of the operation is given with illustrations.

Heavy Duty Diesel Engines.—Atlas Imperial mechanical injection fuel Diesel engines are described in a catalogue issued by the Atlas Imperial Engine Company, Inc., Oakland, Cal. An explanation of the mechanical problems met in Diesel engine design with illustrations and characteristic details of engines in small and large power units are given together with numerous views showing application of these engines in stationary and marine practice.

Cast Iron Storage Tank.—The Conveyors Corporation of America, Chicago, has issued a new booklet describing its American cast-iron sectional storage tank which is designed for holding loose, bulky, dry materials for storage or transfer. The booklet is illustrated with engravings showing the tanks in use at a number of well-known plants. Diagrams give details of construction and a comprehensive table of weights and measures is included.

Welding Repairs.—Methods of utilizing welding in repair work in England are outlined in a bulletin recently sent out by Barimar, Ltd., Oxford street, London, England. Details for engine and general machine repairs are explained with photographs of the work in process and in the finished state.

Seamless Steel Tubes.—The third of a series of four bulletins describing the manufacturing processes carried on by the Standard Seamless Tube Company, Pittsburgh, Pa., has recently been sent out. The subject dealt with in this case is the cold draw department.

WE GUARANTEE that of this issue, 6,650 copies were printed; that of these copies 3,768 were mailed to regular paid subscribers, 209 were provided for counter and news company sales, 199 were mailed to advertisers, 85 were mailed to employees and correspondents and 2,389 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 61,400—an average of 5,582 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The Showdown

AT this writing it is believed that the President will call a special session of Congress in November to take up the proposed shipping legislation. The failure of the United States to adopt a constructive shipping policy has prevented private capital from investing in marine securities. It has caused us to tie up so many vessels that over one-half of the entire idle tonnage of the world is composed of American ships. It has compelled the Shipping Board to carry in its own vessels, under a system of managing operators, the far greater majority of our foreign overseas commerce.

Delays and postponements of the time of settlement of the shipping problem have injured our merchant marine and our foreign trade. If the House of Representatives is not given an opportunity to act on this measure before the appropriation bills of the short session come up, there is no telling when action can be obtained. In other words, the time has arrived when the needs of the country demand a showdown on the question of protection for the American merchant marine.

Protection has been freely given to our manufacturing industry. It has raised our standard of living, which affects every other industry, including shipping and shipbuilding. It has made domestic investments inviting and it can be safely said that American capital will not seriously attempt the shipping business until protection is assured.

Protection is right in principle until an industry is able to stand on its own feet. The shipping bill contains many provisions for developing our shipping. It is based on the facts and findings of the best committee of marine experts, irrespective of their political affiliations, that the Administration could get together. There will be an honest difference of opinion on some of the features which are more or less discriminatory in nature but the main provision, whether it is called a subsidy, compensation or a retaining fee for National defense should be favorably acted upon immediately.

The Jones Act compels the Shipping Board to operate our vessels under Government ownership until private capital can be interested in taking them over. The present board is doing this work as efficiently as it is possible to do it where the incentive of private interest is lacking. Government ownership is an abomination to the average business man but it is better to maintain a merchant marine under the present conditions than to drop back to where we were in 1914. If the Great War demonstrated anything, it proved the fact that a merchant fleet is necessary for our commercial prosperity and absolutely essential for the security of the Nation.

The Cost of New Ships

A STUDY of the bids offered for the construction of vessels during the last two months indicates that the bottom prices have been reached and that prospective owners who are delaying placing their orders will lose rather than gain by playing a waiting game. It is known that quite a number of coastwise vessels are contemplated for which contract plans and specifications have been or are being prepared. Special types of vessels for foreign commerce are also under consideration and the passage of favorable shipping legislation would undoubtedly bring them out.

While it is not believed that a contract for the construction of a new ship can be placed as cheaply as it could have been last spring, nevertheless better prices can be obtained now than in the future. In this connection the recent raise in the wages of the employees of the United States Steel Corporation, the continued increase in unfilled steel tonnage orders, the results of the railway strike and the coal strike are very good indications that the cost of both wages and materials is upward.

It is true that several shipyards have made sacrifices during the last year in order to get contracts so that they could hold their organizations together. But this will not be repeated except in exceptional cases for reorganization and

retrenchment having been accomplished and there is nothing to be gained by taking a contract that means a loss.

Shipowners should realize that shipyards are governed by the same laws that apply to other lines of business. They can produce the cheapest only when the volume of work is sufficient to keep all of their departments constantly busy. Therefore to hold up work, particularly on a rising market, until the shipyards are in a position to demand high prices, as they certainly will be if the subsidy is passed, is almost certain to result in a loss of both time and money.

Reserve Engineers

THOSE who have followed the sea or lived in the desert never forget. Whether it is the vastness of the ocean on the one hand or the lone level sands stretching far away on the other, there is a fascination for those who have traversed these great bodies of land and water which typifies as nothing else on this earth of ours the greatness of the universe that once felt will always remain.

So we are glad to learn that the engineers which the shipping depression have cast upon the beach have formed a shore division of the Ocean Marine Engineers' Association. These men who, temporarily at least, are forced to seek employment ashore hold sea-going certificates of which they are justly proud. And the possession of one of these tickets entitles the holder to mingle with the men on active sea duty and keep in touch with the news of the sea.

Without such an organization the whereabouts of the engineers leaving the beach would become unknown. The Government would thus lose a ready means of manning their ships in a time of emergency and this would be no small undertaking; for a minimum of four engineers is required for each vessel. So it is hoped that this organization of reserve engineers will meet with encouragement and the best way we can help these men who are loyal to the sea but must have work is to advise the Ocean Marine Engineers' Association, 15 Whitehall Street, New York city, of any job on a stationary plant that comes to our attention.

The South Has the Most to Gain

ALTHOUGH the shipping bill has not been made a party measure, nevertheless the chief opposition to it lies in the Democratic party. The senators and representatives from the South must be blind to the interests of their section of the country, if they allow their deep rooted prejudices against protection to influence their votes against a subsidy for shipping.

Knowing, as they must, that Southern ports are nearer to the great continents of South America and Africa and, at the same time, closer on the average to the center of production of the United States, which is a short distance southwest of Indianapolis, Indiana, it seems unbelievable that any Southern statesman would oppose any reasonable legislation that would develop our carrying trade under the American flag.

With Europe impoverished, no part of the country has more to gain from the development of American foreign commerce in the next fifty years than the South. Africa and South America are two vast undeveloped sections of the world. Their natural wealth and almost unlimited resources present opportunities to American genius and capital that are not to be compared with anything that Europe has to offer. Both of these continents look to the United States for the money, equipment, materials and skill that are necessary in a period of development.

If the Southern representatives vote against the shipping bill they will be doing nothing less than opposing the building up of a very lucrative trade that would naturally flow through the ports of the Southern states. And, furthermore, they would be directly aiding England and Germany with their advantage of cheap production to obtain for themselves the trade of Africa and South America. The United States cannot hope to secure her share of this commerce which will probably be greater in value than that from any other countries for some time to come if she does not bend every effort and utilize every opportunity to facilitate its development.

Prohibition That Does Not Prohibit

THE enforcement of Attorney General Daugherty's ruling will not cause the high seas to be one bit dryer. It will simply mean that those who desire the privilege of drinking wines and liquors *en voyage*—and in this class must be included a large percentage of Americans as well as foreigners—will select vessels over which we have absolutely no jurisdiction outside of the three mile limit.

Attorney General Daugherty holds that the intent of the framers of the eighteenth amendment in the light of the context was plainly to prevent the transportation or consumption of liquor wherever the United States held jurisdiction. We believe that the question of selling liquor on ships never entered their minds because there were so few American passenger ships engaged in foreign trade at that time.

One of the greatest arguments in favor of national prohibition was that it was impossible to keep one State dry while its neighbor was wet. This is just as true of vessels plying on the same route. Foreign vessels cannot be controlled and there will be an inducement to every member of the crew of American vessels to become bootleggers.

Neither is it the custom to examine passengers' baggage on embarkation. To do so, if it can be legally done, as the Constitution forbids the customs to tax exports, would be only one more incentive to avoid American ships and not to do so would mean that a large percentage of the class of people who can afford to travel abroad would carry their own. Whatever may be one's personal opinion of prohibition he certainly knows that it is far better to have the sale of good liquor under the control of the captain of the ship than the uncontrolled indulgence in bad liquor in the staterooms at all hours of the day.

If the passengers on our ships were limited to Americans, enforcement of the Volstead Act would be more consistent but we rely on securing our share of the foreign passenger trade. In preventing citizens of other countries from enjoying their customary beverages we are adopting a "holier than thou" attitude which is bound to work to the disadvantage

of American ships in more ways than one. For instance, in order to build up foreign trade, we have to do business with merchants of other countries. If these merchants when traveling on American ships feel insulted or, on account of prohibition, elect to travel on vessels of our competitors, we are apt to lose their trade. And this trade is vital to the prosperity of every employer and employee in the country.

Attorney General Daugherty's ruling also affects every American cargo ship in the foreign trade; for our vessels will be prohibited from accepting shipments from one foreign port to another, if there is any liquor in the manifest. Taking it from whatever angle you wish, this ruling will accomplish nothing but harm to American vessels. And by placing such a handicap on our merchant marine, we may find in a time of emergency that we lack the vessels that would give our Navy the power to prevent just such a catastrophe as occurred in 1914.

However, there are many ways in which a prosperous merchant marine could save us vast sums today. Mr. Plummer stated in his address that 68 percent of the import and export business passing through Vancouver, B. C., last year was American. What a loss this was to the American railroads passing through the Middle West!

Indeed, both American rail and water transportation bear a vital relation to our business prosperity. And they should be co-ordinated so there will be no necks of the bottle in the future where railroad cars are backed up in the freight yards waiting for an opportunity to get their contents aboard ship. A subsidy is needed to place American ships in a position efficiently to serve the railroads and the country but foreign lines will pay for that subsidy in loss of business. It will take time for the railroads to catch up with their equipment but a close co-operation with American shipping would mean a material increase in efficiency through expedition in handling cars at seaport terminals and in other ways.

Co-operation of Rail and Water Transportation

ONE of the most important provisions of the pending shipping bill is that which provides for the creation of a joint board made up from members of the Interstate Commerce Commission and the United States Shipping Board; this board to have the function of securing proper co-operation of rail and water transportation.

Once again the prosperity of our farmers is vitally affected by the lack of adequate railway facilities. According to an address recently delivered by Mr. Samuel O. Dunn before the annual meeting of the Associated Business Papers, "the farmers cannot ship the crops they already have harvested, and the wheat has not all been threshed and the corn is not yet gathered. Every single industry in the country is reporting that its shipments, and many that their production, are being restricted by lack of transportation."

The railroads lack freight cars and locomotives while the merchant marine has a surplus of cargo ships. Government regulations preventing the railroads from earning adequate returns on their capital is the primary reason why the railroads have not expanded sufficiently to take care of increased production. Lack of Governmental protection against the international competition of cheap wages and cheap building costs has been the cause of our marine troubles.

In both cases these short-sighted policies are causing enormous losses. Commissioner Plummer, of the United States Shipping Board, in an address before the Convention of Industrial Engineers on October 18 said, "the fact that the grain producers of Nebraska and Iowa alone within the last month lost one hundred and fifty millions of dollars for the reason that there has been a complete breakdown of transportation, due to the starvation of our railroads for several years, shows why the people of the Middle West have a special interest in securing adequate transportation for their products." It does not seem possible that there will be a lack of ships for some time to come but it is only a short time since our farmers and business men lost hundreds of millions of dollars because there were neither foreign or American ships to take their goods.

The Shipbuilding Outlook

IF the statistics of the past are any indication of what the future has in store, then the prospects are good for a renewal of activity in the shipbuilding industry. Whether the United States receives its share of the new tonnage is another matter and of course depends largely on the shipping policies adopted by this Government.

From a summary of the age and size of steam and motor vessels from the 1922-23 edition of Lloyd's Register Book, we are informed that there are 61,342,952 gross tons of steam and motor vessels of 100 gross tons and over in the world today. This compares, according to the figures of the Bureau of Navigation, Department of Commerce, with 45,403,877 gross tons of steam and motor vessels of 100 gross tons and over existing in the year 1914.

Returning to Lloyd's Register Book we find that 7,068,449 gross tons of existing shipping are over 25 years old and 5,888,923 gross tons are over 20 years old. As 20 years is considered the period of useful life for a ship, 12,957,372 gross tons of ships are now due for the shipbreaker. Added to this, by admission of the Shipping Board, at least, 3,000,000 gross tons of the American vessels built during the war are not efficient and should be scrapped. Next, for the purpose of comparison with 1914, we must remove at least 3,500,000 of the existing 4,806,400 gross tons of oil tankers as this class of vessel is the result of the development of oil for fuel. Removing these 19,457,372 gross tons from 61,342,952 gross tons leaves 41,885,580 gross tons today as compared with 45,403,877 gross tons in 1914.

Now Secretary Hoover recently stated that the world's commerce doubles every 15 years. The value of our foreign commerce in 1907 was $3,315,272,503, and last year, in spite of the depression, it was $6,994,178,926. English shipyards are experiencing a marked revival in new contracts and we may be sure that our maritime rivals are planning for the future. It is our opinion that the world commerce will more than double during the next 15 years and in such places as China, South America and Africa an even greater increase is probable. Are we going to get our share of this business?

The A B C of the National Shipping Bill

Common Sense Answers to Pertinent Questions Concerning the Proposed Shipping Legislation

By C. A. McAllister

Q. What is a subsidy?

A. Standard Dictionary says: "Pecuniary aid directly granted by Government to an individual or commercial enterprise deemed productive of public benefit.

"Synonyms: Aid, allowance, bonus, bounty, gift, grant, indemnity, pension, premium, reward, support, etc.

"Illustration: A nation grants a *subsidy* to an ally, pays a *tribute* to a conqueror."

The authors of this dictionary could not have expressed the present situation in shipping in better terms. Unless we pay a *subsidy* to our own ally (American ships in the foreign trade) we will have to pay a *tribute* to our (commercial) conquerors.

Q. Should the pending bill be called a "Subsidy Bill"?

A. Yes, if we stick to the dictionary definition as we should, but in the minds of many prejudiced people the term "Subsidy" is taken as synonymous with some subtle kind of graft, or the giving to shipowners of something they do not earn. A better term would be a payment to shipowners as a "Retaining Fee" for keeping their vessels ready for instant use in the national defense, and to use them in times of peace to market our surplus products abroad.

Q. If foreign ships can and will carry our products cheaper than we can carry them, why not let them do it?

A. There is every reason why we should not do so, the principal of which are:

(*a*) We must sell our surplus products of the farm, mine and factory in the same competitive markets in which the owners of the foreign ships are trying to sell similar surplus products of their own. A swell chance we will have to sell our goods from our rivals' delivery wagons!

(*b*) Every merchant ship we have under our own flag is needed for our national defense in time of war. In a world wide war such as we have just emerged from, and which may happen at any time again, if we had only fighting ships upon which to depend, we would be as impotent as fire engines without hose connections to hydrants trying to fight a conflagration.

(*c*) Abraham Lincoln once said in defense of the principles of protection: "If I buy a pair of trousers abroad for $10, I have the trousers and they have my $10; if I buy them at home for $12, I have the trousers and we have the $12 at home." The same reasoning applies to our owning ships: We have the ships and keep the freight money they earn in our own pockets.

Q. How long will we have to subsidize ships?

A. In all probability, within ten years we will have learned the shipping business and applied American talents and methods to the problem, so that at the end of that period our merchant marine can look after itself. Just remember that when we started to manufacture steel, now one of the greatest of our industries, our mills could not compete with foreign manufacturers any better than our ships, now unaided, can compete with foreign ships. By a wise system of protective measures during its infancy, the American steel industry now leads the world and brings millions of dollars of reserve to our people. Many others of our leading industries have been built up in the same manner. Had it not been for the wide vision and constructive attitude of our statesmen in the past generations, America today would have been purely an agricultural country and not the leading manufacturing and commercial country of the world. Let the present generation of statesmen prepare for continued prosperity by enacting this most essential legislation to make permanent an efficient merchant marine under our own flag.

Q. Cannot American ingenuity overcome our handicaps in shipping?

A. That is an entirely mistaken assumption, based on our national self-conceit. In the foreign shipping business we are, as yet, but novices and have much to learn. Other nations have inventive geniuses as well as we.

The greatest modern invention looking towards economical propulsion of ships is the Diesel engine, invented by a German. Other nations have made vast strides in adopting this engine, while we have just started. Unless the industry is protected in its infancy by our Government, as all other nations have done for their start in shipping, we cannot be counted among contenders for our own overseas trade. After a reasonable period of protection, say ten years, it is quite probable that American methods and inventions may, by that time, have given us sufficient shipping experience and resourcefulness to keep in the contest unaided.

Q. Why are ships of such great importance anyhow?

A. In the beginning according to Biblical history and scientific deduction the entire surface of the globe was covered with water. Today over two-thirds of the surface is water. The land is divided up among some 17,000 islands, more or less, as continents are merely overgrown islands. The human race, ever restless, wanders from land to land and exchanges commodities in order to live. Hence since the beginning of the earth's habitation ships have been one of the most important factors in the development of the human race, and will continue so to be, unless aviation develops to such an extent as to replace water navigation. Even at that, aircraft are but ships in another form. Without ships America would never have been discovered and settled, so the very existence of this country is due to shipping.

Q. What interest has the farmer in shipping?

A. More, perhaps, than any other branch of industry. In the first place we produce fifteen percent more goods in this country than we can ourselves consume. Unless we have our own ships to dispose of this surplusage of the farm, mine and factory the country cannot, as a whole, be prosperous. Foreign ships will not aid us in finding markets for our exports. Unless the country at large is in a prosperous condition the farmer cannot sell in our own country at prices which will pay him to raise food products for a people whose buying is restricted to absolute necessities to maintain life.

From 1914 to 1916, the first years of the Great War, the farmers could not get their cotton, wheat, beef, pork and corn out of the country, although the demand was great, because we had no ships of our own and the merchant vessels of the countries we had been depending upon for ocean transportation were either too busily engaged by their own

Governments or were afraid to take the risk of being captured by the enemy. The result was that all our seaports were congested with vast quantities of farm products and the men who raised them could not get their money although sales had been made.

If we are put out of the overseas shipping business, foreign vessels can make the rates so high as to debar the products of our farms, until all available wheat, cotton, etc., from competing countries have been sold. In the past summer, when the nation-wide coal strike had forced us to buy thousands of tons of coal abroad, the freight rates on that indispensable commodity started to soar. We had many ships laid up, and as soon as a number of them were put into the coal business, the freight rates immediately dropped.

Suppose we had had no ships of our own, what would have happened? Let the farmer apply this condition to his wheat, corn, pork, beef and other products.

Q. Will not this proposed legislation benefit only the shipping trust?

A. An American shipping trust exists only in the brain of the cracker-box orator and his kind. There are about 1,500 ships under the American flag (of over 1,500 tons burthen), which could be used in our foreign trade. Of these, the Government itself owns over 80 percent. The remainder are distributed among 72 firms and many individual owners, the largest single privately owned fleet consisting of 53 vessels.

Competition is so keen among these ships and with foreign ships, that the laws of the United States recognize and permit conferences to be made, in order to stop rate cutting to such an extent as to cause financial ruin to the shipowners engaged in certain trades.

In the American shipbuilding industry competition is now, and has been for many years (excluding the four year war period) so keen that many yards have been forced into bankruptcy. Many more will follow unless the Government aids shipping. Without ships and shipbuilding facilities this country will be on an island, depending on the ships of our commercial rivals for ingress and egress. If the time comes when we must defend ourselves from foreign aggression, we will be as helpless as a lion without teeth or claws.

Q. Will not the cost of this subsidy bill be a great burden on the taxpayers?

A. Positively it will not; on the contrary, it will save money to the taxpayers, for the following reasons:

(*a*) The pending measure only provides subsidies for a period of ten years. For the first year the cost will only be $15,000,000. The average cost for the entire period will not be over $40,000,000 per annum, according to expert testimony.

(*b*) We are now spending at the rate of $50,000,000 per annum to operate the Shipping Board fleet, which is found absolutely necessary to carry on our foreign trade and to prevent exorbitant freight rates being levied on us by foreign carriers. Almost all this sum will be saved by selling the ships to private operators.

(*c*) We now have over 10,000,000 tons of ships in the possession of the Government, as a direct salvage from the Great War. As private owners cannot operate them successfully, there is but little demand for them and they are laid up. Vessels not used, no matter how well cared for, rapidly deteriorate. Some are being sold at ridiculously low prices, because that is now the only way they can be sold. The recent sales of Government-owned ships do not average much over $10 per ton. If this bill is passed, and private owners can operate the ships successfully by means of its benefits, the sale value for the remainder of the Government fleet will advance rapidly. This enhancement of value alone should more than offset the entire ten years' cost of the subsidy, so it is plainly to be seen that the taxpayer will be directly benefitted by a reduction instead of an increase in his taxes.

Indirectly he will be greatly benefitted by the increased sales of our goods in foreign markets, and the general prosperity which such will bring. For example, the leading Shipping Board line to South America, while being operated at a comparatively small loss, succeeded in increasing its trade to the ports at which its vessels touch 107 percent in one year. All branches of our industries benefit by such an increase, directly or indirectly.

Q. Why does it cost more to operate ships under the American flag than under foreign flags?

A. Simply because Americans in every walk of life are accustomed to, and demand, higher standards of living, more comforts and more luxuries than the people of any other nation under the sun. Every industry and profession in this country is protected, either by a tariff or by over 3,000 miles of sea, except our shipping engaged in the foreign trade. The latter must meet the fiercest competition from the shipping of all other maritime nations, as soon as our vessels leave our ports. You cannot expect Americans to build our ships and work at the same rate of wages paid in foreign shipyards, nor can you expect our citizens to go to sea and operate our ships at the same rates of pay fixed by lower standards of living in foreign countries and paid to the men on foreign ships. Experts have conclusively demonstrated that under normal conditions the workmen in American shipyards and the crews on American ships must be paid 25 percent higher remuneration than men similarly employed in building and manning foreign ships. With a tariff on all competitive commodities, and immigration restrictions on all branches of the labor market, would it be fair to make our men in the shipyards and on our ships work without protection of some kind from their government? Our forebears all came to this country because of the greater opportunities and better living conditions in this country. Why not keep up the standards established here in the only branch of industry not now protected in some direct or indirect manner?

Q. If we amend and modernize our navigation laws, will not our ships then be able to compete for the ocean trade?

A. Such a procedure will help, as certain portions of the laws and regulations do need to be amended. It has been proposed that we adopt the Merchant Shipping Act of Great Britain in its entirety, so that our ships would be as little restricted and hampered as English ships are reputed to be. Even if we did that, helpful as it might be, American ships could not compete with British ships. In reality, although there has been much oratory and many editorials expended in railing against our so-called "moth-eaten" navigation laws, they are not nearly so bad as we have been led to think. Three years ago a committee of expert shipping men appointed by the Shipping Board spent several months in studying the various laws relating to ships and found but a few changes to be necessary. The laws are now being re-codified in consonance with that committee's recommendation and will soon be presented to Congress for its action.

The much discussed and condemned Seaman's Act was found to need amendment in but a few respects, to make it entirely acceptable to these practical shipping men. As a noteworthy example of the findings of this committee, it is but necessary to consider the heretofore almost universally accepted idea, that American ships were greatly handicapped by discriminations in regard to the net tonnage, assigned by our Government officials, being noticeably in excess of the net tonnage assigned by the British government to vessels of the same type and dimensions. If such were the fact, our vessels would have had to pay heavier taxes, canal tolls, port charges, etc. The Navigation Laws Revision Com-

mittee, however, found that no discriminations existed, and so reported to the Shipping Board.

Revision of our navigation laws will help in an indirect way but will be entirely inadequate to keep our ships on the seas without some direct financial help such as carried in the legislation now pending.

Q. Does not partisan politics enter into this proposed legislation?

A. If there is any one policy before the American public in which partisan bias does not enter, it is in regard to our shipping. Both the great political parties in their platforms for many years past have gone on record as favoring the rehabilitation of our merchant marine. There are, naturally, differences of opinion as to how this best can be done. Many statesmen have advocated discriminating import duties as the best solution, and in fact such a policy is now the law of the land, but both former President Wilson and President Harding are of the opinion that such policy is inadvisable because of certain treaties now extant, hence that law has not been enforced. Many people are still firmly of the opinion that the existing law would solve the problem, but there is no hope of its being enforced. In consequence the pending subsidy bill appears to be the only practicable solution. As both political parties are pledged to the upbuilding of our merchant marine, they should unite in support of what is apparently the only policy which is workable. Democrats should not forget that Thomas Jefferson, the founder of their party, was the most pronounced advocate of a strong American merchant marine. If he were alive today, it is more than probable that he would advocate the pending bill in view of the circumstances now existing. Republicans should bear in mind that their great leaders, McKinley and Roosevelt, were staunch advocates of subsidies as the best method of building up the merchant marine. Wilson and McAdoo are responsible for the existence of the great fleet of vessels we now own. To show the non-partisanship of the present measure, it is only necessary to call attention to the fact that its leading proponents in the Senate today are Senator Ransdell, a Southern Democrat, and Senator Jones, a Western Republican.

President Harding, formerly a senator from an interior state, where there is no direct interest in ship ownership, is and has been one of the staunchest advocates of the upbuilding of our foreign trade through the medium of American ships; thereby showing broad and statesmanlike vision. Grosvenor and Hanna, leaders in previous attempts to pass similar legislation, were both from Ohio, which shows that shipping is not an issue belonging to the people along our coasts, but a vital national necessity.

Q. How will the shipping bill benefit labor?

A. The creation of a permanent and efficient merchant marine by means of the Subsidy Act, will furnish additional employment to over 100,000 Americans on board ship, in the shipyards, the steel mills, the iron mines, and in the many other industries which are necessary to build and operate ships for the foreign trade. Every man thus employed must be well fed, and the American farmer will be benefited by raising and selling the food to them and their families.

Q. Why did the Washington Conference make the shipping bill imperative?

A. Without this encouragement to our merchant marine, we will build no more ships. We have, by international agreement, already stopped the building of fighting vessels. Hence, without any work to do, shipbuilding will become, in America, a lost art. Without shipbuilders and shipbuilding facilities this nation will be helpless for both commerce and for self-defense—an emasculated giant in the family of nations.

Q. What do our maritime rivals think of the shipping bill?

A. Our rivals for the world's trade view with great alarm the prospects of the passage of this bill, and their emissaries masquerading, in many instances, as patriotic citizens are spreading insidious propaganda and doing their utmost to defeat the measure. This is the strongest evidence possible why the bill will benefit America, and why it should receive the support of patriotic Americans.

Fuel Conservation Committee Starts Fuel Oil School for Marine Engineers

In line with the efficiency of operation and fuel conservation program instituted by Vice-President Jos. E. Sheedy of the United States Shipping Board, and which is being promulgated by the Fuel Conservation Committee of the Shipping Board, headed by Captain C. A. McAllister, and including in its members Commander R. D. Gatewood, Mr. E. H. Peabody, Major G. M. Talbot, Mr. D. M. Myers, Mr. Maurice Healey and Mr. F. B. Webster, an offer made by Secretary Denby of the United States Navy to the Shipping Board that a school of instruction in fuel oil burning by the Navy Department be established for the benefit of the officers of the Merchant Marine has been accepted and the school started on October 23.

Licensed American marine engineers of the grade of second assistant or higher on active duty are eligible for the course. The course is intensive, as indicated in the schedule below:

First Day

9 to 10	a. m.	Lecture on oil characteristics.
10 to 11	a. m.	Lecture on curves.
11 to 12	a. m.	Inspection of testing plant.
1 to 2.30	p. m.	Lecture on specific gravity, baume, hydrometer, viscosity, moisture and sediment, flash and fire points.
2.30 to 4	p. m.	Demonstration in laboratory of above features.

Second Day

9 to 10	a. m.	Safety precautions.
10 to 12	a. m.	Lecture on combustion—Orsat, draft gauge, pyrometer.
1 to 4	p. m.	Laboratory—operation of Orsat, draft gauge, pyrometer, interpretation of CO_2 curves and excess air.

Third Day

9 to 10	a. m.	Lecture on atomization—cleaning tips, atomizers.
10 to 12	a. m.	Demonstration of spray with tip testing apparatus, and in boiler.
1 to 4	p. m.	Laboratory work—relation of flame colors, smoke, and gas analysis.

Fourth Day

9 to 10.30	a. m.	Lecture on refractories and insulations.
10.30 to 12	a. m.	Demonstration of test furnaces.
1 to 4	p. m.	Laboratory work installing brickwork and plastic.

Fifth Day

9 to 10	a. m.	Lecture on water testing outfit and water treatment.
10 to 12	a. m.	Laboratory use of water testing outfit.
1 to 2	p. m.	Summary lecture by commanding officer of fuel oil testing plant and school.
2 to 4	p. m.	Examination.

The United States Navy, in conjunction with the Fuel Conservation Section of the Shipping Board, will conduct the course, which will be directed by Lieutenant Commander E. R. Norton. The lectures will be given by officers of the Navy and technical aides who have demonstrated the successful methods of operation on naval vessels which have made our ships the most efficient of any oil-burning vessels afloat.

Graduated Compensation of Shipping Bill Explained

Mail and Passenger Ships Receive More Than Cargo Ships Because They Cost More to Construct and Operate

By Winthrop L. Marvin*

A SUMMARY of the provisions of the National Shipping Bill, such as was contained in the October issue of MARINE ENGINEERING AND SHIPPING AGE, may logically be followed by a statement of the reasons justifying National aid, first to the cargo ships and second to the passenger, mail and cargo liners that together constitute a balanced merchant marine.

First of all, the mileage-tonnage compensation provided for cargo ships of a speed of 11 knots and less is intended by the government officials to constitute an approximate offset to the lower wages of officers and men and the lower cost of subsistence on shipboard of our principal foreign competitors, who are the shipowners of Great Britain, possessing as they do nearly one-half of the active overseas shipping tonnage of the world.

A series of careful estimates based upon actual ship payrolls, prepared by the United States Shipping Board and confirmed by the records of private American shipowners, goes to show that the basic compensation of one-half of one cent for each gross ton of a vessel for each one hundred nautical miles covered by the vessel in the foreign trade of the United States represents approximately the difference between the wage and food cost of a representative American ship and of a representative British ship of the same type and capacity.

Following are tabular comparisons of the wage scales of representative American and British steamers of a good average size, or 6,000 tons gross register, both engaged in North Atlantic commerce:

COMPARISON OF AMERICAN AND BRITISH PAY-ROLLS.

	American Scale (Privately-Owned-Ship) Per Month	British Scale Per Month		
Master	$275	£45	0	0
Mate	165	20	10	0
Second Mate	140	16	0	0
Third Mate	125	13	0	0
Carpenter	70	12	10	0
Boatswain	..	11	10	0
Able Seamen (6)	285	60	0	0
Ordinary Seamen (2)	70	11	0	0
Chief Engineer	250	24	10	0
Second Engineer	165	20	10	0
Third Engineer	140	16	0	0
Fourth Engineer	125	13	0	0
Deck Engineer	70	11	10	0
Oilers (3)	165	33	0	0
Firemen (9)	450	94	10	0
Coalpassers (3)	120	30	0	0
Steward	105	14	10	0
Cook	90	13	10	0
Second Cook	70	9	10	0
Messboys (3)	90	8	10	0
Radio	90	13	10	0
	$3,060	£492	0	0

Pound sterling converted @ $4.43	$2,179.56
American scale	$ 3,060.00
British scale, present exchange, $4.43=£1	2,179.56
Difference	880.44
Subsistence difference	240.00
Total monthly difference	$ 1,120.44

*Vice-president and general manager, American Steamship Owners' Association.

Annual difference for 11 months at present rate of exchange $12,324.84

Compensation, as proposed, 6,000 tons gross × $0.005 = $30.
Allow 35,000 miles per year = $10,500 annual compensation for this type.

These wage scales respectively embody the standard rates in practice at the present time on American and on British cargo steamers, with white crews. It is made clear that the American steamer, considering both wage and subsistence costs, is at a disadvantage of $1,120.44 per month, or of $12,324.84 for eleven months, as compared with its British competitor. According to the best available estimates, the 6,000-ton American steamer, on a basis of a subsidy of one-half of one cent for each gross ton for each one hundred nautical miles traveled in the foreign trade, will earn a total compensation or subsidy in eleven months of $10,500. This subsidy of itself falls somewhat short of meeting the higher wages and subsistence of the American ship, so that the indirect aids in the National Shipping Bill must be depended on for the exact equalizing of conditions between American and British cargo steamers of like type and tonnage. It is obvious from these facts as given that, so far as the compensation or subsidy is concerned, not a dollar of it can rightfully be regarded as a bonus for the shipowner. Every dollar of this compensation goes into the pockets of the American officers and seamen, who are the direct beneficiaries of the proposed legislation.

Competitive Conditions Make Compensation Necessary

It may be urged that American shipowners are now operating steamers in the foreign trade, and are paying out of their own pockets the difference between American and British wages and subsistence. So they are, but nothing is more unmistakable than that they cannot and will not continue so to do, any more than they were operating ships and paying higher wage and subsistence costs before the world war, when, as is generally known, the American flag, except as borne on a certain few subsidized mail routes, had virtually left the ocean, and more than nine-tenths of our export and import trade was being conveyed by the ships of foreign nations. What was once will most certainly be again, unless the full compensation proposed in the National Shipping Bill, to even up competitive conditions and give American ships a fair chance, is promptly and fully made available. If the proposed compensation is not given, experience demonstrates that American cargo ships will be forced out of overseas trade, and their officers and men will cease to exist as seafarers.

There is agreement among an overwhelming majority of the American people of both political parties that the tariff laws of the United States shall be so adjusted as to give American labor a fair chance against competing foreign labor in manufacturing and in agriculture. Can any man who calls himself an American give a reason why there should not be equivalent fair play for our labor on the sea?

Increased Compensation Required for Faster Ships

For passenger, mail and cargo steamers operating on regular lines, and generally of a speed of from 12 knots upward, graduated, increasing rates of compensation or subsidy are

provided by Section 404 of the National Shipping Bill. For ordinary cargo steamers of 11 knots and less, generally described as of the "tramp" class, though running on regular routes, the rate of compensation, as has been said, is one-half of one cent for each gross ton for each one hundred nautical miles traversed in the foreign trade. The 12-knot steamer, the lowest speed that is likely to be employed in the passenger, mail and cargo service, is given by the Shipping Bill an additional compensation of one-tenth of one cent, if her speed is 12 knots or less than 13 knots; of two-tenths of one cent, if her speed is 13 knots and less than 14 knots—and so on upward until an additional compensation of two and one-tenth cents per gross ton for one hundred nautical miles sailed is provided for steamers of a speed of 23 knots or more—or a total compensation for such ships of two and six-tenths cents per gross ton for each one hundred miles covered.

The reasons for this graduated increase of compensation to the faster ships are that these faster steamers invariably cost more money to build and operate and, therefore, involve a very great increase in capital investment. A Senator, criticising the terms of the National Shipping Bill, recently asked why a 10,000-ton cargo steamer should receive compensation of only $15,000 a year, while the *Leviathan* would receive $900,000.

Compensation for Leviathan Analysed

This is an extreme comparison. There are many 10,000-ton cargo steamers, but there is only one *Leviathan* under the American flag. Ten thousand-ton cargo steamers were being built in American yards before the world war for from $60 to $65 per deadweight ton. Such ships during the war, because of the emergency, and soaring prices of materials and wages, cost as high as $200 per deadweight ton. But 10,000-ton cargo steamers are being sold in all countries now at an average price of $30 per ton. It is understood that the *Leviathan* originally cost in Germany before the world war about $7,000,000 to construct, and approximately $8,000,000 is now being expended for the reconditioning of this mighty steamer.

Considering further, that the 10,000-ton cargo steamer can be navigated by 35 men, while the *Leviathan* has required a crew of 1,000 men—and considering the difference in the cost of stores and fuel which the cargo ship and the *Leviathan* will consume, it is manifest that the 10,000-ton cargo steamer is not over-compensated nor is the *Leviathan* over-compensated, though the latter ship may receive $900,000 a year. The British government, it should be remembered, gave a subsidy to the Cunard Line in 1903 of about $1,050,000 a year for the two ships *Mauretania* and *Lusitania*, after having lent, at the low interest rate of 2¾ percent, about $12,000,000 for the construction of the two steamers. The *Mauretania* is of 30,000 tons gross register. The *Lusitania* was of 30,000 tons gross register. The *Leviathan* is of 54,000 tons gross register. If the *Leviathan* receives a compensation or subsidy of $900,000, or $16.67 per gross ton per year, it will be not dissimilar from the total annual subsidy of $17.50 per ton per year which the British government gave under a twenty-year contract to the *Mauretania* and *Lusitania*.

All Maritime Nations Have Aided Establishment of Passenger Lines

All maritime governments in the world have found it necessary in the last eighty years to pay considerable sums of money to create and to maintain their National lines of passenger, mail and cargo steamers. Great Britain was the pioneer in this subvention or subsidy policy, beginning with the founding of the Cunard Line in 1839, with a subsidy of $425,000 a year. There is not the slightest reason to believe that the United States can create and maintain essential National lines of passenger, mail and cargo steamers in any other way than that pursued by Great Britain, France, Germany, Japan, Italy, Spain or any other nation that has owned or owns fleets of express ocean steamers. Historically, all such large, fast vessels of the naval reserve have been subsidized, or if not subsidized have received equivalent compensation. This is the purpose of the paragraphs of Section 404 of our National Shipping Bill, which provide graduated increasing rates of compensation for regular passenger, mail and cargo services of a speed of from 12 knots to 23 knots and upward. The problem is different from the problem of the cargo ships pure and simple, where the compensation provided is only enough to cover the difference in wage and subsistence costs between like American and foreign vessels.

Liners under all flags and in all times have demanded special consideration from their governments. The cost of constructing and operating steamers of more than ordinary commercial speed fitted for mail and passenger service is such that these fast services have under no flag been able to succeed without very generous National assistance. Cargo steamers of from 9 to 11 knots, out of the excess of tonnage built during the world war, are now being sold in all countries for an average of $30 per deadweight ton. Passenger, mail and cargo steamers of more than usual commercial speed would cost, if now constructed, all the way from five to upwards of ten times as much per ton, and would cost correspondingly to maintain and operate. These are substantially the main reasons why the rates of compensation provided for liners in the National Shipping Bill are higher than for 9 to 11-knot cargo or "tramp" steamers.

The United States Shipping Board has a small fleet of existing mail, passenger and cargo steamers for sale, but the cost of these, if they are relatively new ships, has been the equivalent of many times $30 per deadweight ton. And as to the older German ships, the cost of these also will prove exceedingly high when they have been properly reconditioned for liner service.

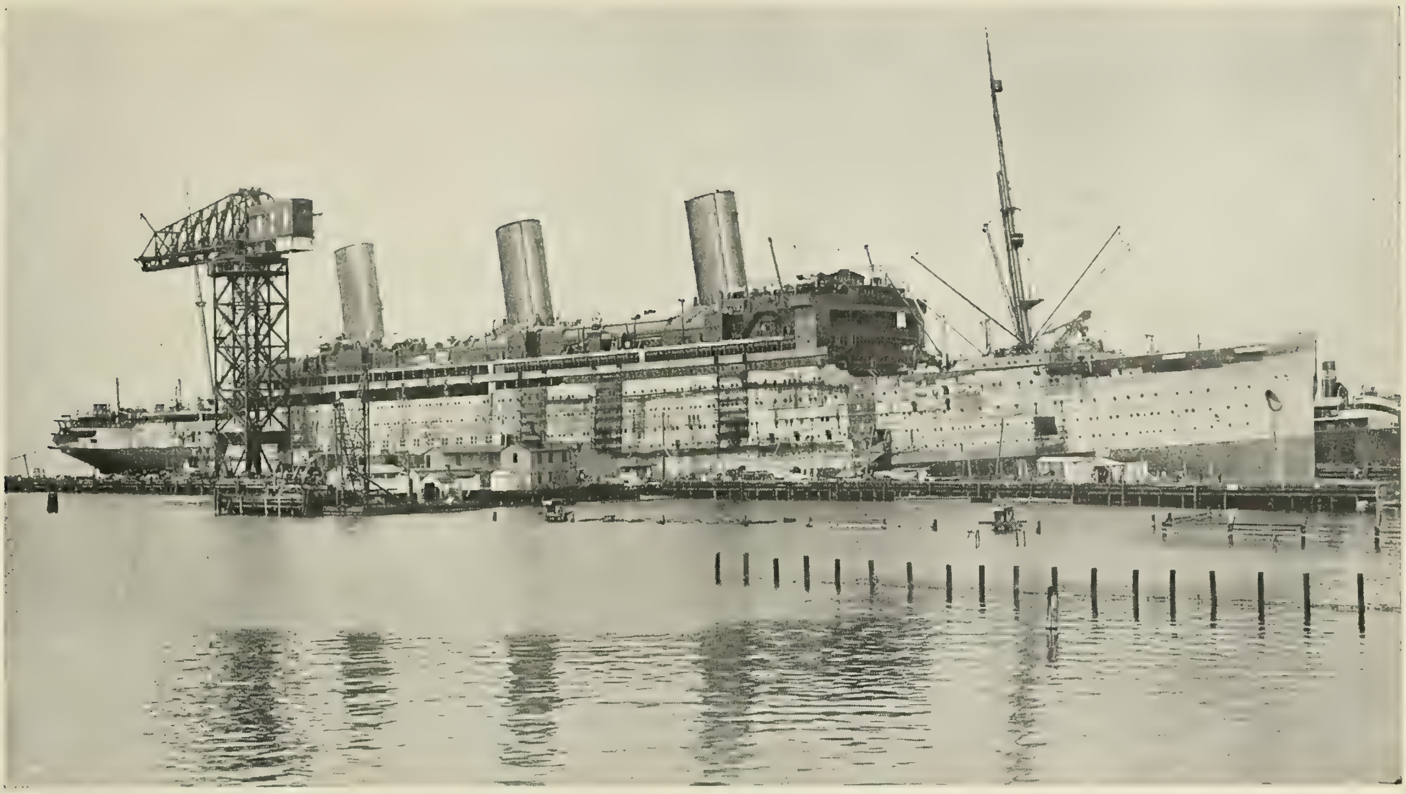
New Tariff Rates in Ceylon

Consul Vance, Colombo, cables the Department of Commerce that the new customs tariff of Ceylon which went into effect provisionally from August 25, as announced in *Commerce Reports* for September 4, has been adopted with certain modifications. The import duties on motor trucks, cotton goods and fish are to remain unchanged, while the advance on automobiles, motorcycles and soap is more moderate than had been proposed. The final rates on the more important articles of trade with the United States are as follows:

Articles	Former duties Ad valorem	New duties Ad valorem
Automobiles	7½ percent	10 percent
Motorcycles	7½ percent	10 percent
Motor trucks	7½ percent	7½ percent
Toilet soap	7½ percent	10 percent
Agricultural machinery run by other than human or animal power	Free	2½ percent
Cotton goods	5½ percent	5½ percent
Fish, dried or salted, per hundredweight	Rupees 0.75	Rupees 0.75
Meat, frozen or refrigerated	Free	2½ percent Ad valorem
Paper machinery	Free	2½ percent
Articles not specified	Ad valorem 7½ percent	Ad valorem 10 percent

The proposed advance in the export duty on tea grown on the island has been increased from 1½ Ceylon cents to 3 cents per pound.

The duties in Ceylon apply equally to imports from all sources.



View of Steamship Leviathan at Fitting Out Pier of Newport News Shipbuilding and Dry Dock Company, Showing 120-Ton Hammer Head Crane on the Pier for Placing Heavy Equipment on the Vessel. The Reconditioning of the Steamship Leviathan

Newport News Shipbuilding and Dry Dock Company Converting the World's Second Largest Vessel Into the Finest Transatlantic Liner Afloat

WHEN the proposal to recondition the *Leviathan* as a first class passenger liner was under consideration after the vessel had completed her service as an army transport during the world war, the Government was confronted with a task far greater than had ever been attempted in the history of shipbuilding. When completed in Germany in 1914 the vessel was the largest liner in the world; since then she has been surpassed in size by only one other vessel, the White Star liner *Majestic,* which, except for a matter of 2,269 gross tons increase in measurement, is practically a sister ship of the *Leviathan.*

After completion, the *Leviathan* (ex-*Vaterland*) made only three voyages across the Atlantic under the German flag, as at the outbreak of the war she was interned in New York harbor where she remained until the United States entered the war in 1917 when she was seized by the Government and pressed into service as a troopship. During the two years she was used as a transport the vessel was stripped of her furnishings and all decks below the weather deck were cleared so that she could carry from 11,000 to 12,000 troops on each voyage instead of the 3,400 passengers for which she was originally designed. After going out of commission as a transport the vessel remained idle at her pier in New York harbor for a period of two years.

Plans and Specifications Required

In reconditioning the vessel for the transatlantic passenger trade, therefore, not only was the toll of her active war service, and subsequent enforced idleness, to be reckoned with but also, due to her construction abroad, plans of the hull and machinery were unavailable, except from her original owners at a prohibitive price. The first step necessary, therefore, was the preparation from the ship itself of plans and specifications for the work.

Through arrangements made by the United States Shipping Board with the International Mercantile Marine Company, New York, this work was successfully carried out under the supervision of William F. Gibbs, chief of construction of that company. In accordance with these plans and specifications contracts were awarded by the United States Shipping Board, Emergency Fleet Corporation on February 15, 1922, to the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., for reconditioning and conversion of the vessel to an oil burner and for repairs and machinery; also to Gimbel Brothers, New York, for the equipment of the steward's department and for a library, and to Gibbs Brothers, Inc., engineers, New York, for the supervision of the work.

Cost of the Work

The cost of placing the *Leviathan* in commission in accordance with these plans will be approximately $8,200,000, distributed as follows:

Newport News Shipbuilding and Dry Dock Company

Reconditioning and conversion to an oil burner	$5,595,000
Repairs and machinery	515,000

Transatlantic Passenger and Mail Steamship Leviathan

General Information

Service: Highest Class Passenger & Mail service, transatlantic trade.
Builder: Blohm & Voss, Hamburg. Reconditioned by Newport News Shipbuilding and Dry Dock Co.
Owner: U. S. Shipping Board.

GIBBS BROTHERS, INC.	
Supervision	182,000
MISCELLANEOUS	
Moving ship to contractor's yard, insurance covering removal, new anchors and chain, moving ship to dry dock, dry docking, trial trip and maintenance and guarding of ship for 14 months during reconditioning	1,352,000
Total	$8,190,000

Upon award of the contracts the vessel was moved, under the personal supervision of Mr. Gibbs, to the yard of the Newport News Shipbuilding and Dry Dock Company, orders were placed by the shipbuilders for material, some 200 contracts were placed with sub-contractors for equipment and supplies and the work, to be completed in 14 months, was begun. As an indication of the completeness and accuracy of the plans and specifications and the efficiency and skill of the contractors it is noteworthy that up to date not a single extra charge has been incurred, a condition seldom achieved with vessel reconditioning contracts of far less magnitude.

SCOPE OF THE WORK

The work involves extensive structural changes in the hull with a view to increased strength and safety, the conversion of the vessel to an oil burner, the overhaul and repair of all machinery, the new construction of all quarters below the weather or *D* deck, the reconditioning, decoration and furnishing of all passenger accommodations and crew's quarters, installation of complete new galley and pantry equipment of the most modern type, complete new and improved electric wiring, steam heating and plumbing systems throughout the ship, improved ventilation and drainage systems, changes in the engine room and fireroom ventilation to add to the safety of the vessel, and the installation of new and improved equipment of American manufacture for the safe and efficient navigation and operation of the vessel. The work is being done under special survey of the American Bureau of Shipping to meet the requirements for the highest classification of the Bureau. In general the scantlings are all in excess of the American Bureau requirements and the workmanship and materials conform in every respect to the requirements of the United States Steamboat Inspection Service.

The vessel has five steel decks extending the full length of the hull, four decks in the superstructure and additional decks in the forward and after holds. The 13 transverse watertight bulkheads, which originally extended to *F* deck, have all been tested to *F* deck and two in the forward holds have been strengthened and made watertight to *D* deck and two others, the forward collision bulkhead and the one between boiler rooms 1 and 2, have been made watertight to *E* deck. Intermediate beams have been fitted on *L*, *K* and *J* decks forward, the double bottom forward of boiler room 4 has been converted into fuel oil tanks, fuel oil deep tanks have been built in the forward holds and service oil tanks and pump rooms in the former coal bunkers alongside the boiler rooms.

Extra oil-tight bulkheads have been constructed at frames 277, 261, 253 and 236 and a centerline oil-tight bulkhead from frame 224 to 293. The scantlings of all new construction in the fuel oil tanks are in excess of the requirements of the American Bureau of Shipping for a pressure due to a head of water up to the level of *F* deck. For the fresh water tanks the scantlings are for a pressure due to a head of water up to *E* deck.

In bringing the main watertight bulkheads up to the American Bureau requirements extra local stiffening has been provided and the size of and the riveting in the heel and head brackets of the stiffeners have been increased. During the survey of the bulkheads it was found that in several instances rivets had been omitted where holes had been provided for them and in such cases new rivets were driven up.

Due to the greater subdivision of the hull forward of the engine rooms, the strengthening and extension of the bulkheads, the elimination of many of the watertight doors in the bulkheads and the rearrangement of the ventilating systems, to the engine and boiler rooms, the protection of the vessel against flooding due to collision or grounding is substantially increased. The safety of the ship is also materially increased by the addition of 9 new firescreen bulkheads making 20 in all which are installed in the passenger quarters.

PASSENGER ACCOMMODATIONS

The arrangement of the passenger accommodations is shown by the accompanying plans. Above *D* deck, the former arrangement of the rooms, including the first class public rooms and suites, will in general be retained. Below *D* deck the passenger and crew's quarters are principally of new construction.

The interior decoration and furnishing of the first and second class accommodations, under the supervision of Walker and Gillette, architects, New York, will surpass in beauty, comfort and convenience anything previously attempted in a floating hotel. The draperies are being furnished by W. and J. Sloane, New York; the carpets (about 20,000 square yards) by the Bigelow Hartford Carpet Company, New York, and Alexander Smith and Sons, New York; the Oriental rugs (about 3,000 square yards) by Costikyan and Company, New York; equipment for the first and second class gymnasiums by A. G. Spalding, Chicopee, Mass., and furniture by the Orsenigo Company, Long Island City, N. Y., Smith and Sons, New York, and Sons-Cunningham Company, New York. Large quantities of the cabinet work are being manufactured by the Newport News Shipbuilding and Dry Dock Company. Eleven new electric elevators are being installed by the Otis Elevator Company, New York, 3 for first class passengers, 1 for second class passengers, 1 for the engineers and 6 for freight, in addition to 5 new electric dumbwaiters.

On the bridge deck numerous changes are being made in the officers' quarters, due to the reduction in size of the ventilating trunks to the boiler rooms giving space for additional rooms, including among others a library for the captain's suite and a smoking room for the deck officers. Further aft on *A* deck a similar smoking room is being fitted for the engineers.

On *A* and *B* decks are the principal first class public rooms and promenade space. On *C*, *D*, *E* and *F* decks amidships are the first class staterooms, special suites and the main dining room and galleys.

The second class accommodations are on *C*, *D*, *E*, *F*, *G* and *H* decks aft of the machinery space and further aft on *D*, *E*, *F*, *G*, *H* and *J* decks are the third class accommodations while the crew and steerage quarters are forward on *D*, *E*, *F*, *G*, *H* and *J* decks.

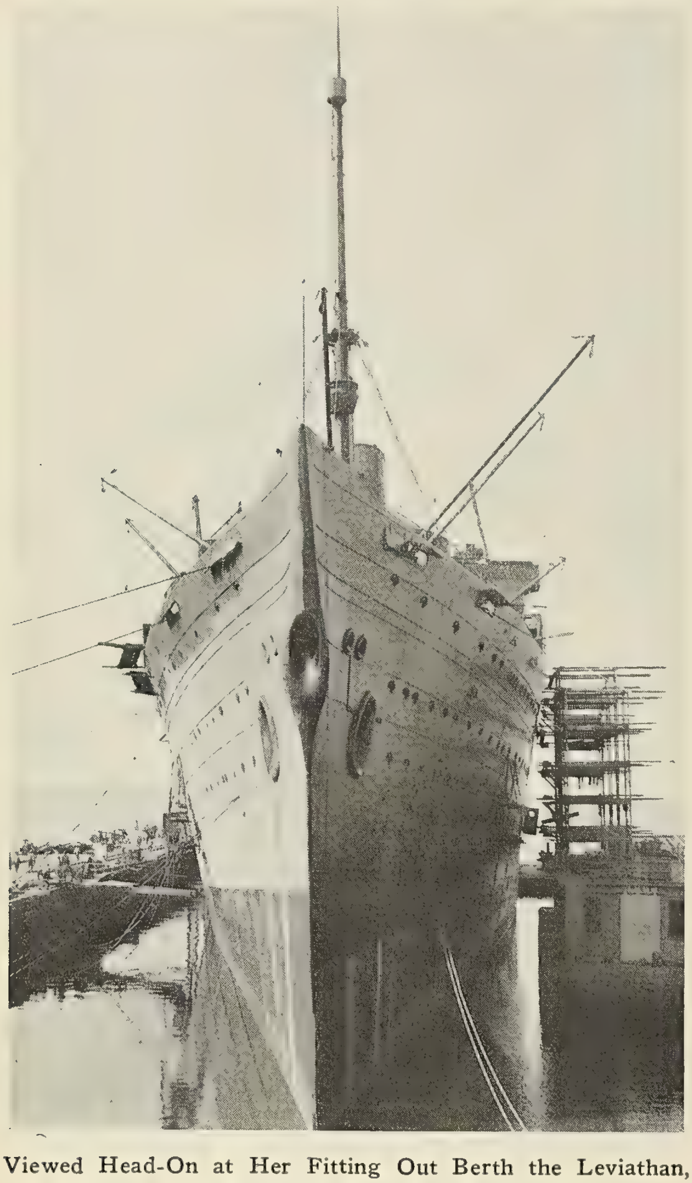
The new flooring in general is of American Lit-O-Sil-O decking, supplied by the Marine Decking and Supply Company, New York, covered with linoleum, carpet or rugs. In the new construction about 150,000 square feet of heavy plyboard either Haskelite (56,000 square feet) or Roddiswood, supplied through the United States Plywood Company, New York, and about 100,000 square feet of Vehisote, supplied by the Pantasote Company, New York, are used.

So extensive is the work being done in the new construction, reconditioning, decoration, furnishing and fitting out of the passenger accommodations that no adequate description of it can be given in the space available at this time. This phase of the work will be dealt with in a later article when the vessel is completed.

PROPELLING MACHINERY OVERHAULED

Propulsion of the *Leviathan* is by four shafts driven by direct connected Parsons turbines arranged as follows, from

forward aft: Port inboard shaft, high pressure ahead and high pressure astern; starboard inboard shaft, high pressure astern and intermediate pressure ahead; port outboard shaft, low pressure ahead and low pressure astern; starboard outboard shaft, low pressure ahead and low pressure astern. In full speed condition steam is admitted first to the high pressure, then to the intermediate and then to the two low pressure turbines. For maneuvering, steam is admitted from the boilers direct to both the high and intermediate pressure turbines and then from the high pressure to the port low



Viewed Head-On at Her Fitting Out Berth the Leviathan, in Spite of Her Enormous Size, Has the Appearance of a Swift Yacht or Destroyer

pressure and from the intermediate to the starboard low pressure turbine.

On the maneuvering board in the operating room are valves by which, in the event of the breakdown of any shaft, a change can be made to the other shafts in 3 or 4 minutes. In this way a major breakdown to the machinery could occur without affecting the safety of the vessel or her passengers in the slightest degree.

In reconditioning the ship the main turbines and all of the auxiliary machinery, fittings and equipment are being thoroughly overhauled and put in first class condition.

Boilers Converted from Coal to Oil Burning

Steam is furnished at 248 pounds per square inch by 46 Yarrow type watertube boilers located in 4 boiler rooms and the boilers are being converted from coal to oil burning. The finished installation is guaranteed to burn from 500 to 2,240 pounds of Mexican crude oil of 10.6 to 10.8 degrees Beaume having a viscosity of 6,000 Saybolt seconds at 150 degrees F. per boiler per hour under service conditions. The original coal burning equipment will be retained for possible reconversion at some future time should this become desirable.

The oil burners at the boilers, of which 5 are fitted to each boiler, are of the Peabody type supplied by the Peabody Engineering Corporation, New York.

To provide a total fuel oil capacity of about 9,563 tons of 11 degree Beaume Mexican fuel oil with the tanks 97 percent filled the following tanks will be used: 25 double bottom tanks, 13 deep tanks and 8 service tanks, all provided with connections for filling. The double bottom fuel oil tanks are all forward of frame 150 at the forward end of boiler room No. 4, where a cofferdam is built to isolate the fresh water tanks aft. The deep tanks are located in holds 1, 2 and 3 forward of No. 1 boiler room and extend up to *L*, *K* and *J* decks, respectively. The service tanks are located in the former side coal bunkers, 2 in each boiler room, 1 on either side, extending from the tank top to *J* deck, except in boiler room 4, where a cofferdam is built above the tank top to isolate the service tanks from the fresh water in the double bottom tanks below. Fifty Pneumercator gages are connected to the tanks.

The deep tanks in No. 3 hold will be arranged as settling tanks. The fuel oil will be transferred from the double bottom tanks to the deep tanks for settling and thence to the service tanks at the sides of the boiler rooms. Arrangements are made for pumping oil from any deep tank to any service tank while transferring oil from any double bottom tank to a deep or settling tank.

Oil Transfer System

Duplicate service systems are provided in the three forward boiler rooms, with pumps (9 by 6 by 10 inch vertical duplex), heaters and strainers and the transfer systems (10 by 12 by 12 inch vertical duplex pumps) are also in duplicate. Boiler room 4 will have 2 duplicate sets of service pumps of smaller size (7½ by 4½ by 10 inch) as the boilers in this room will be used in port. The oil heaters are of the Griscom-Russell type.

An adequate system of oil heating coils is provided in each service and oil storage tanks capable of raising the temperature of the oil from 40 to at least 130 degrees F.

In boiler room 4 a new donkey boiler, supplied by the Consolidated Shipbuilding Corporation, Morris Heights, New York, is installed to supply steam direct to the service pumps in boiler room 4 and to the manifold controlling steam to the oil heating coils in the service tanks in this boiler room.

Overflow System

In every compartment used for storage of fuel oil an overflow system is provided so that the highest pressure in the tank cannot exceed that due to a head of oil up to the highest point of the overflow system. The system is divided into two main sections, one for the tanks forward of the boiler rooms and the other for the tanks in way of the boiler rooms. The overboard overflows of both systems are at the side of the vessel about 5 feet above *G* deck and are fitted with nonreturn valves to prevent shipping of seas in rough weather.

Fire Protection in the Boiler Rooms

With the conversion of the vessel from coal to oil burning it became necessary to provide the utmost protection against the fire hazard involved in the handling, storage and burning of fuel oil. For this purpose a very complete Firefoam fire extinguishing system is being installed by Charles Cory and Son, Inc., New York, designers and installation engineers of the system.

In general, the system comprises two solution tanks having a capacity of 3,500 gallons each, installed on *H* deck over boiler room No. 3, which are used to store the "A" and "B"

Firefoam solutions. Two independently driven pumping units, one electric and the other steam, are employed to pump the solutions to any one of the four firerooms, or to any filling station. The Northern Fire Apparatus Company's positive displacement rotary pumps syphon the solution from the tanks and discharge into the feed lines at a rate of 400 gallons of each solution per minute. One twin unit is driven in tandem by a 50 horsepower Albergen-Curtis steam turbine and a duplicate unit by a 50 horsepower Diehl Navy standard watertight motor.

The solutions are conveyed from the pumps to the various compartments and mixed in specially designed distributors, which are installed in such a manner over the tank tops and other places where oil can collect that the foam, formed by impinging the solutions in these distributors, will be completely spread over the surface of the fire. These distributors are also placed in all filling stations on *F* and *G* decks. In addition to the distributors, each boiler room is equipped with four Firefoam hose hydrants, with the exception of No. 1 boiler room, in which there are five. The hose is intended to be used to combat incipient fires above the floors and in pump rooms adjacent to the firerooms.

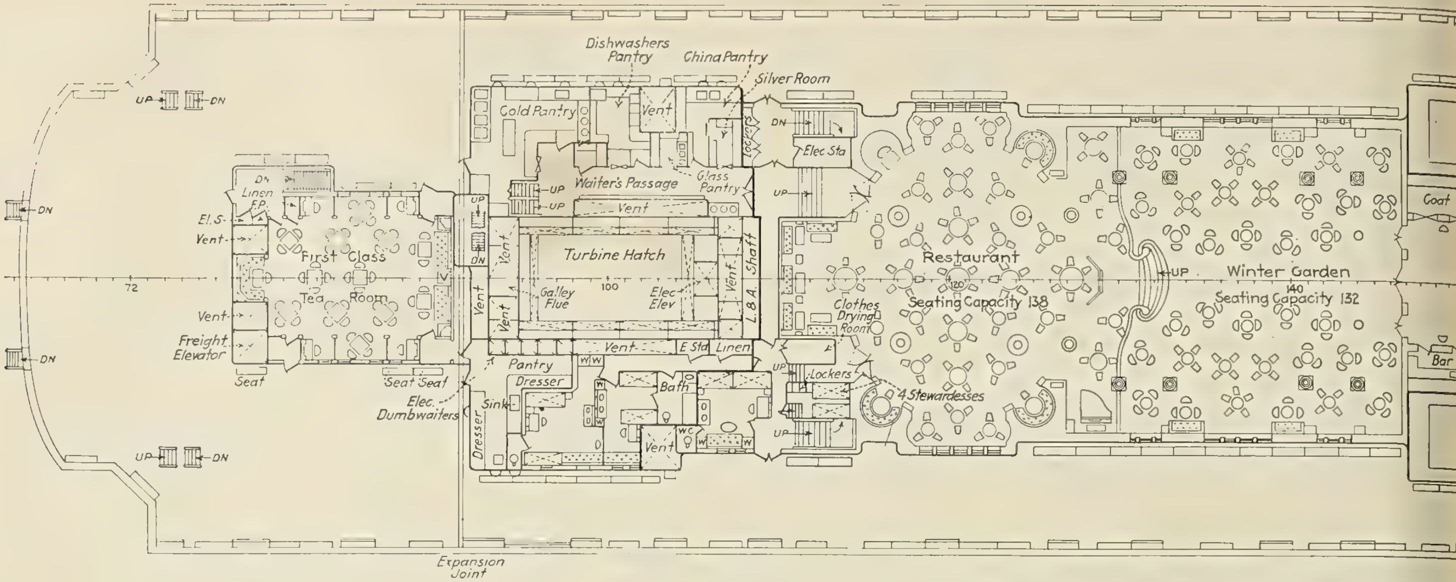
A rather unique method of controlling the various valves and pumping units has been devised. In each fireroom there are located special levers which control the valves supplying solutions to the distributors. Means are also provided in each adjacent fireroom so that, in case of fire, it will be possible to operate the system from an adjacent fireroom, or from the one affected. Separate controls are installed for all hose hydrants. A positive tripping mechanism is used on the control valves, which are operated in pairs on account of the two different liquids. When the tripping device is released, large coiled springs open the valves and eliminate undue strains on the control gear.

Simultaneously with the operation of any one of the controls, whether it is in one of the firerooms or filling stations, an electric contactor mounted on each pair of valves closes the circuit for the automatic magnetic lockout control panel and starts the electric motor driven pumping unit. The closing of this circuit also energizes the solenoid of a Cory electro-mechanical valve controlling the supply of steam to the turbine driven unit. Relief valves permit the solution to return to the respective tanks should the pressure build up above that for which the system has been designed. To provide against failure of the electric current aboard, the mechanical controls to all valves are so connected with the electro-mechanical steam valve that this valve is automatically opened and steam supplied to the turbine driven pumping unit whenever a control lever is operated.

Workmen Coming Off the Leviathan at the Noon Hour. Over 2,900 Men Are at Work on the Vessel Each Day

Heating and Ventilation

An entirely new steam heating system has been installed throughout the ship, designed and tested to withstand the full boiler pressure of 248 pounds per square inch, although the usual pressure carried in the system will not be over 30 pounds per square inch. The radiators, which are installed in all the public rooms and staterooms, with the exception of the steerage and crew's quarters forward, where the air supplied to the rooms is heated by a thermotank system, consist of copper coils designed and built by the Newport News Shipbuilding and Dry Dock Company. By making the steam heating system capable of withstanding full boiler pressure

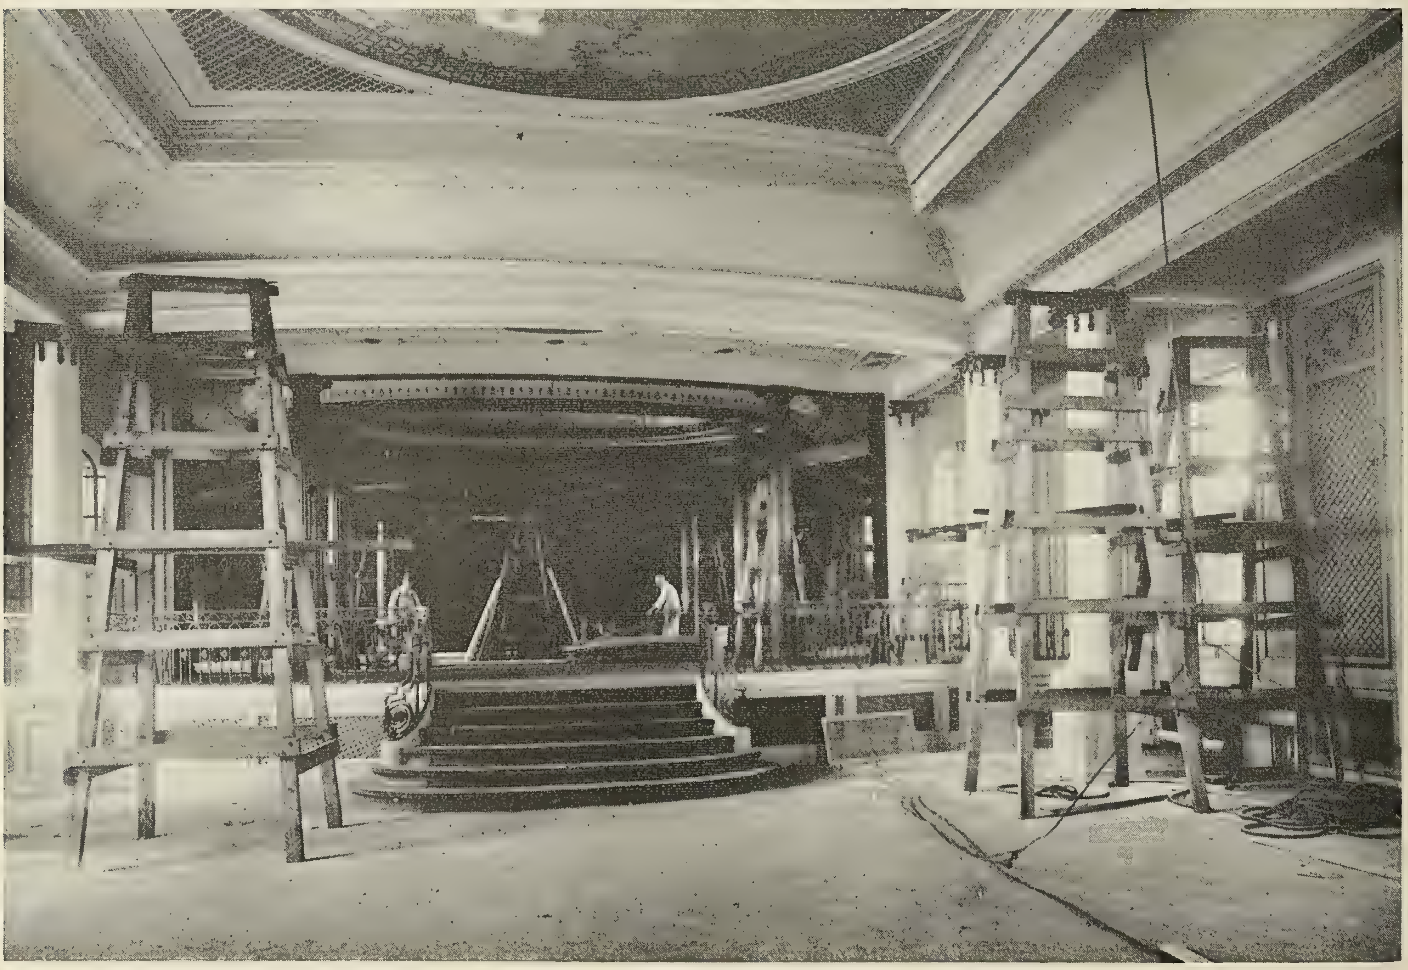


Plan of B Deck, Showing Arrangement of

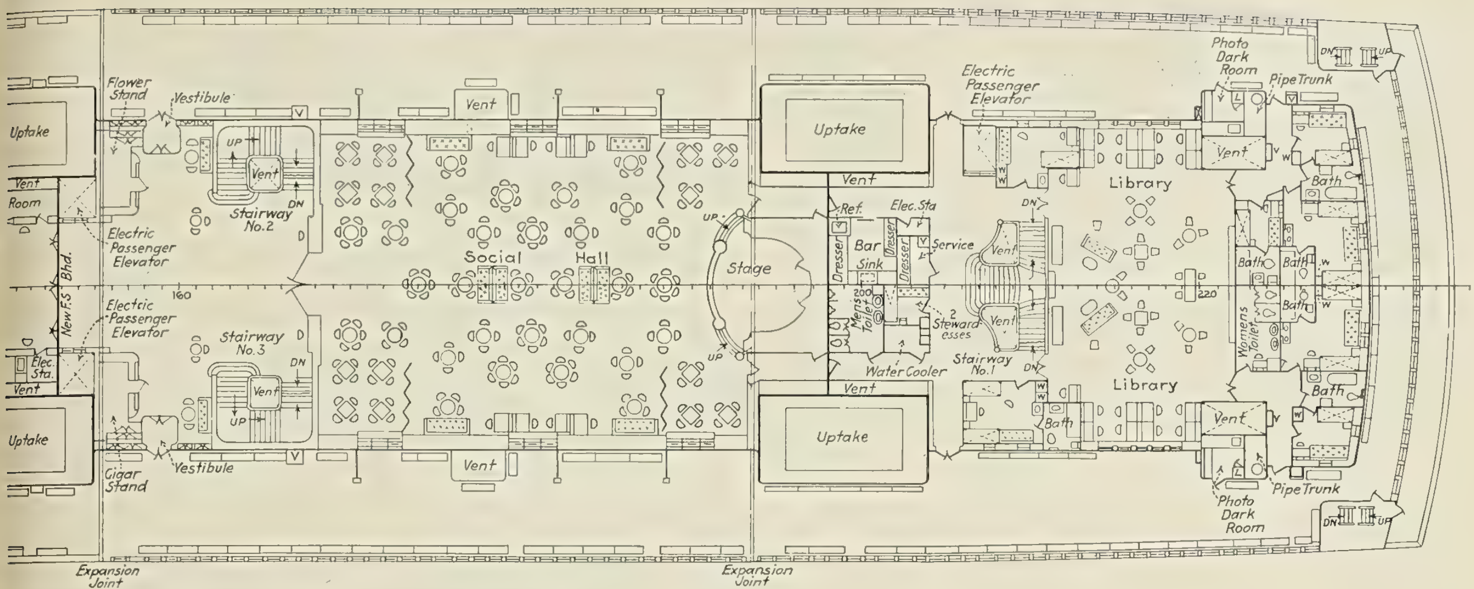
the vessel and passengers are safeguarded against damage or injury due to the possibility of full steam pressure ever being inadvertently admitted to the system.

Ventilation of the ship is accomplished by means of 124 separate ventilating systems, including 58 supply systems, 58 exhaust systems, six circulating fans for the refrigerating rooms and two propeller fans for the battery charging room. With the exception of the two propeller fans and eight blowers of 5,000 cubic feet per minute capacity each for the former coal bunker spaces on *H* deck which will be used for emergency passenger quarters, the ventilating fans, numbering 114, will consist of the old equipment originally installed but overhauled and placed in first-class working condition. The new fans are of the Sturtevant type.

All passenger and crew's quarters are being ventilated mechanically. In the steerage and crew's quarters the air



In the Winter Garden and Restaurant on B Deck the New Electric Wiring Is Complete and the Work of Decoration Is Under Way. The Panel at the Right, Consisting of Green Trellis Work on a Gray Panel With Gold Trim, Shows the General Scheme of Decoration for the Winter Garden

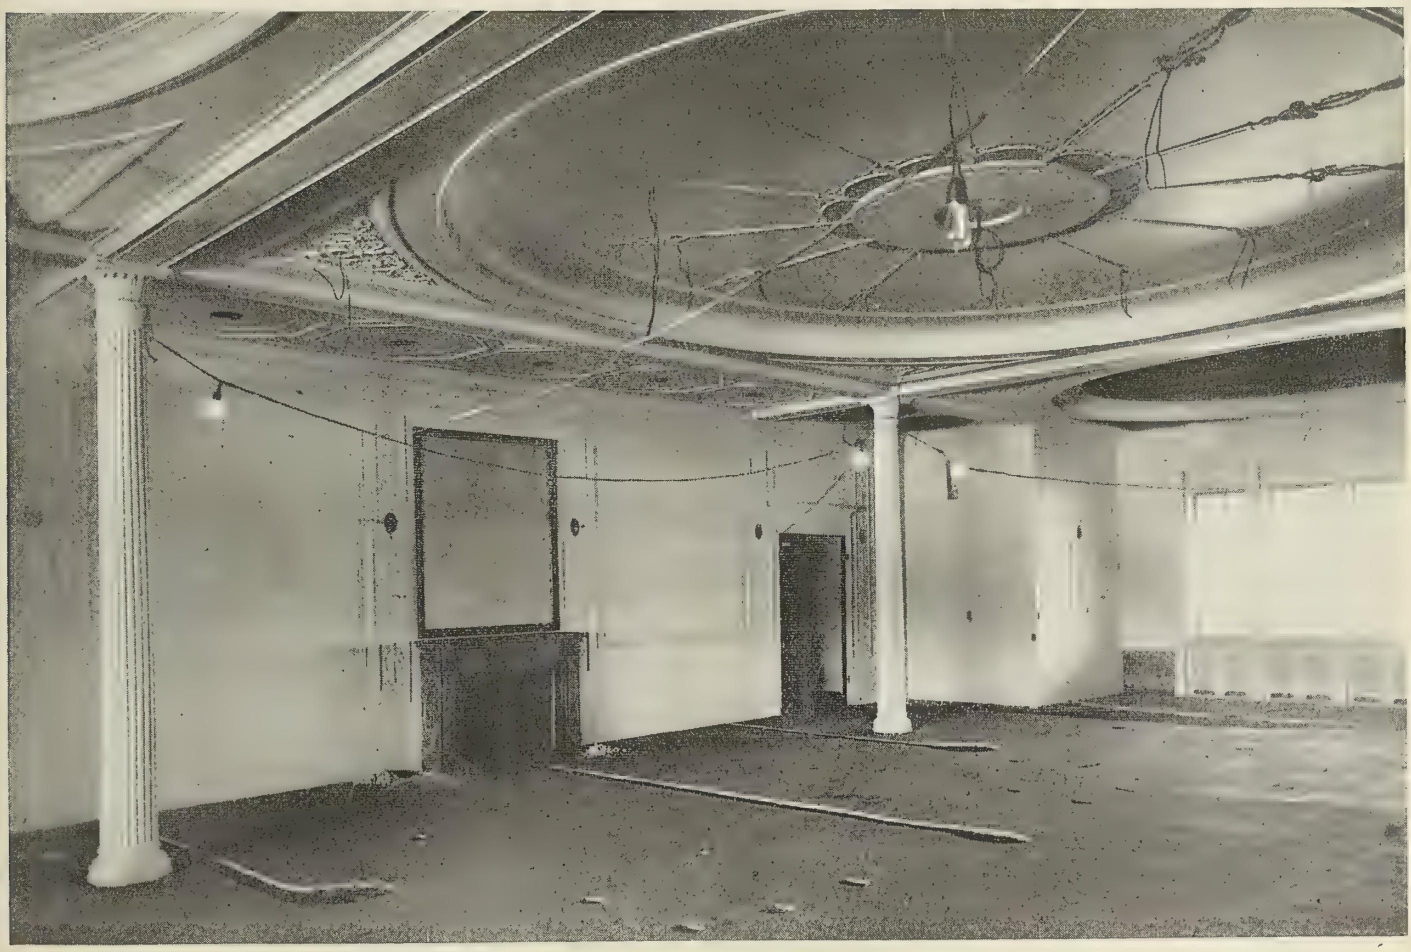


Principal First Class Public Rooms and Promenade

is heated by the thermotank system. Above *D* deck the ventilating ducts originally installed will in general be retained with slight changes. Delow *D* deck, where the accommodations are being entirely rebuilt, the ventilating system is completely rearranged.

Plumbing

All plumbing throughout the vessel has been removed and new plumbing of improved design installed. In all, about 55,000 feet of cold and hot fresh and salt water piping have been installed in the ship. For supplying the sanitary system six sanitary pumps are installed, three on each side of the ship in the engine room. The salt water supply is pumped through a 10-inch pipe to a 5-ton gravity tank located about 35 feet above the bridge deck in the after stack, which is a dummy located directly above the engine room hatch. In this



The Main Library on B Deck Is One of the Few Rooms on the Ship Comparatively Free from Scaffolding and Other Signs of the Activities of the Workmen. Here the Wiring and Ventilating Ducts Are Complete But the Floor, Ceiling and Walls Await the Finishing Touches

Section of the Joiner Shop in the Newport News Yard Where Much of the Furniture for the Leviathan Is Being Manufactured

position the tank gives ample gravity pressure all over the ship.

From this gravity tank a 12-inch supply pipe leads down to a point below *H* deck whence it runs fore and aft the full length of the engine and boiler rooms, supplying water to risers in three trunks.

The main feature of the sanitary system is the arrangement of the gravity tank, which is fitted with a slide valve operated by a float at the top of the supply pipe to the tank. This is so arranged that when water is drawn from the tank the float drops, opens the slide valve and admits water to the tank. When the valve opens the sanitary pump starts and keeps pumping water into the tank until the valve is closed by the lift of the float.

The pressure in the supply pipe from the pump to the tank is always kept at 150 pounds per square inch and is regulated by a governor valve fitted on the steam line to the pump. A diaphragm in the governor valve is connected to the supply line to the gravity tank so that, when the slide valve in the gravity tank opens and the pressure in the pipe falls slightly, steam is admitted to the pump and the pump starts, maintaining the pressure in the line close to 150 pounds per square inch. When the gravity tank is full and the slide valve closes, the pressure in the pipe rises slightly and shuts off steam to the pump.

The object of the slide valve and float in the gravity tank is to make it possible to keep a pressure of 150 pounds per square inch in the supply line so that the fire line can be taken from the same manifold and always have adequate pressure in the fire line system and at the same time have the sanitary supply from the gravity tank to the cold and hot water systems supplied by gravity without interruption.

Fresh water is distributed throughout the ship in a manner similar to that used for the salt water supply described above, except that the pressure in the supply pipe for the fresh water system is lower than that in the salt water supply pipe. In this case the gravity tank is also located in the dummy stack over the engine room hatch. The main supply pipes of the system run fore and aft below *H* deck the full length of the engine and boiler rooms. On *H* deck are located three salt water and three fresh water heaters, each with a capacity of about 20 tons per hour capable of heating the water from 40 to 140 degrees F. The heaters are especially designed so they can be taken apart and each part carried through the door of the compartment where they are installed.

Each section of the hot water system throughout the ship is fitted with a return pipe and a circulating pump located near the heater for the section on *H* deck. With this arrangement hot water is continuously circulating through the system, assuring a supply of hot water at all outlets at the instant a faucet is opened. "Sands" plumbing fixtures are used throughout the ship.

All of the heaters are interchangeable so that if for any reason one is out of commission the supply of hot water is not interrupted.

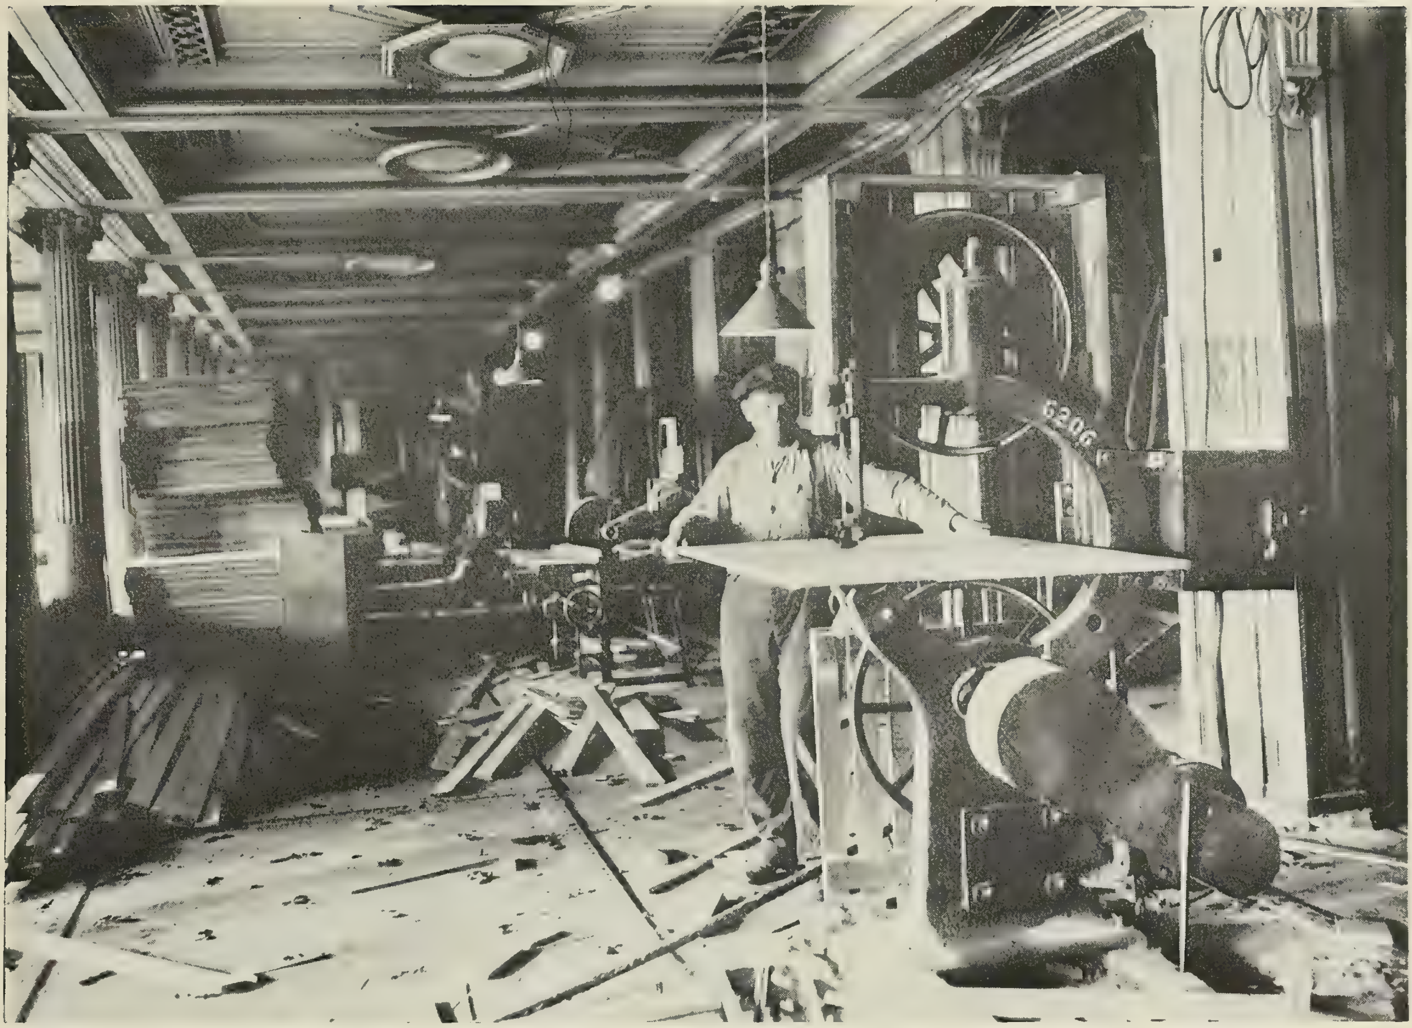
Piping for the hot and cold fresh water and cold salt water systems is of wrought iron while for the hot salt water system it is of copper. Iron pipes $1\frac{1}{4}$ inches and above are expanded into the flanges. In the copper piping the flanges are brazed on. All flanges up to 3 inches are of the hydraulic two-bolt type; above 3 inches the flanges are of the hydraulic type, round with four or more bolts.

Drainage System

All soil pipes, waste pipes from lavatories, floor drains, etc., leading from *G* deck overboard are fitted with a hydraulically operated emergency shut-off valve so that, if, from collision or other cause, one or more watertight compartments are flooded and the vessel sinks below *G* deck, all the valves can be instantly closed by turning a single handle in the engine

Restaurant Galley on A Deck. The New Ranges and Equipment Are Just Being Installed

View in Second Class Dining Room, Where Lit-O-Sil-O Flooring Has Just Been Laid



In the First Class Dining Room on F Deck Wood Working and Other Electrically Driven Machinery Has Been Temporarily Installed and the Room Has Become a Busy Workshop for the Finishing of Panels and Other Wood Work

room, thus preventing water from backing up through the plumbing fixtures and deck drains.

In general the drainage piping is the same as originally fitted in the vessel, except that slight rearrangements have been made to suit new arrangements of fixtures.

Electrical Plant

Electric current on the *Leviathan* is required for lighting over 15,000 electric lamps and for operating approximately 312 motors, ranging in size from 1/6 to 50 horsepower each and totaling 2,150 horsepower. The current is supplied by four 288-kilowatt turbo generating sets originally installed in the vessel and a new 500-kilowatt set supplied by the General Electric Company, Schenectady, N. Y. The new set is of the type which has proved so satisfactory in United States naval vessels and is guaranteed to operate in parallel with any or all of the retained German generating sets.

The generators supply direct current at 115 volts. The turbines of the retained sets are of the Parsons type made by Brown, Boveri & Cie. and are rated at 445 horsepower at 2,000 revolutions per minute. The generators are compound wound with 6 poles, were constructed by the Siemens, Schuckert Company, of Berlin, Germany, and are direct connected to the turbines.

Distribution

The dynamo room in which the current is generated is located in the hold between the propeller shafts, abaft the engine rooms. From the dynamo room the current is conducted to a main primary station on *G* deck, nearly overhead, and from there is distributed about the ship through numerous sub-stations.

When the *Leviathan* was built all of the electrical wiring was installed on the one wire system. In reconditioning the vessel the old wiring from sub-stations to outlets was entirely removed and complete new wiring of the latest navy type was fitted throughout the vessel. Up to the substations the one wire system is used but from the sub-stations to the outlets the two wire system is installed, except in a few cases where leads to some of the motors which were overhauled from the old equipment were retained. Both the wiring and fittings and all electrical equipment installed are designed to meet the most rigid underwriters' tests and inspections.

Special precautions have been taken to lessen fire risks and, as usual in reconstruction work, many interesting engineering problems have been encountered.

Switchboard

The original switchboard on the *Leviathan* was fitted with selective switches so arranged that the generators could not operate in parallel, *i.e.*, each set was assigned to some division of the load. This has been replaced by a new switchboard of the latest type so arranged that the generators run in parallel and pool their loads, which are distributed as required to the various systems. By this arrangement the plant can be operated more economically.

In the main primary station on *G* deck the subdivisions of load are made by grouping circuits at the panels. For lighting they are divided into groups such as general, police gangway, police cabin, etc., and also for festoon and prome-

nade circuits. For power they are divided into groups such as ventilating sets, boat motors, elevators, etc.

Lighting

From the main primary station on *G* deck the circuits are carried to sub-stations where enclosed, dead front panels are installed, fitted with double pole switches, and equipped with N. E. C. fuses. From this point to the lights the circuits are installed on the two wire system.

The fixtures in the public rooms and passenger quarters, supplied by the Sterling Bronze Company, are very elaborate and are especially designed for the locations. In the working part of the ship watertight fixtures are used throughout. Approximately 15,000 electric lamps will be installed, exclusive of festoon lamps and the like which will be provided for decorating the vessel on special occasions.

Wiring

Leaded and armored conductors are used in all places subject to dampness and in all working parts of the ship. In the passenger accommodations armored conductors are used and every precaution is taken in their installation to lessen fire risk, such as the provision of special outlet boxes at fixtures, kick pipes at the decks, guards to prevent injury of conductors and the like.

Electrical Power System

The electric power system comprises ventilating sets for the supply of forced ventilation to all parts of the vessel, electric ranges, elevators, an elaborate system of winches for handling lifeboats and the like, moving picture equipment, etc.

Emergency Lighting

In addition to the above, and wholly separate from it, is an emergency lighting and power system supplied by two 60 kilowatt General Electric generators driven by direct connected Worthington Diesel engines. The emergency sets are located well aft to avoid noise in the staterooms and on *E* deck well above the waterline.

In connection with the emergency system an automatic switching arrangement is provided so that, if the current supply should fail, due to the main generators becoming inoperative for any reason, the emergency circuits would automatically be shifted to current supply, first from an emergency storage battery and then to current from one or both of the emergency generators. The capacity of the emergency generators is sufficient to light all parts of the ship essential for operation, the exit of passengers to lifeboats, the lowering of the boats and the operation of the wireless and other signalling systems.

As a further precaution the switching system is divided to automatically provide separate emergency service for the machinery spaces and other working parts of the ship. All lifeboat lighting is controlled by one switch from the bridge and special features are included such as twelve 500 watt lights for illumination oversides when launching lifeboats.

Interior Communication

All the latest devices for interior communication, signaling, recording, etc., are provided. These systems are controlled from a room on *E* deck well above the waterline. Current is supplied from two motor generators, each with a 17 horsepower 110 volt direct current motor, a 3.75 K. V. A., 112 volt, 50 cycle, single phase alternating current generator and a 7.6 kilowatt 26 volt direct current generator. For emergency use there is a 26 volt storage battery which may be connected to the desired circuits upon failure of the motor generators.

The emergency storage batteries are liberal in capacity and are in duplicate. They are so arranged that one battery must always be connected for operation and only then is the other available for charging, so that after it is charged it can be thrown in prior to the exhaustion of the other battery.

The various interior communication and signalling systems will be briefly referred to under their respective names, in the following:

Searchlights.—One 36-inch high power searchlight, supplied by the Sperry Gyroscope Company, Brooklyn, N. Y., and embodying all the latest developments will be installed and there will be two portable 12-inch incandescent searchlights for use in docking the vessel, picking up buoys, and similar operations.

Telephones.—The ship's service telephone system extends to all parts of the vessel, including each first class stateroom. In all, over 600 telephones are connected to the central station, which consists of a two position lamp type Western Electric Company switchboard. In addition there are the usual telephone systems for the operation of the ship, including the following: Fire and engine room loud speaking system; loud speaking maneuvering circuit, between 14 operating stations; local circuit between ship's officers' quarters.

Fire Alarms.—For protection against fire two systems are employed, one pneumatic and the other manual; both of which are new.

The pneumatic system (Aero fire alarm) functions on the principle of a rising temperature in the compartment or stateroom covered causing an increase of pressure of the air in a small copper tubing which is run through the staterooms and compartments. There are approximately 300 circuits of this tubing, terminating at 26 section panels.

The vessel is divided into twelve sections, panels being located at approximately the center of each section where possible. By means of an annunciator drop these panels indicate which circuit in that section has operated and also transmit the panel section and deck location to the fire watchman's station.

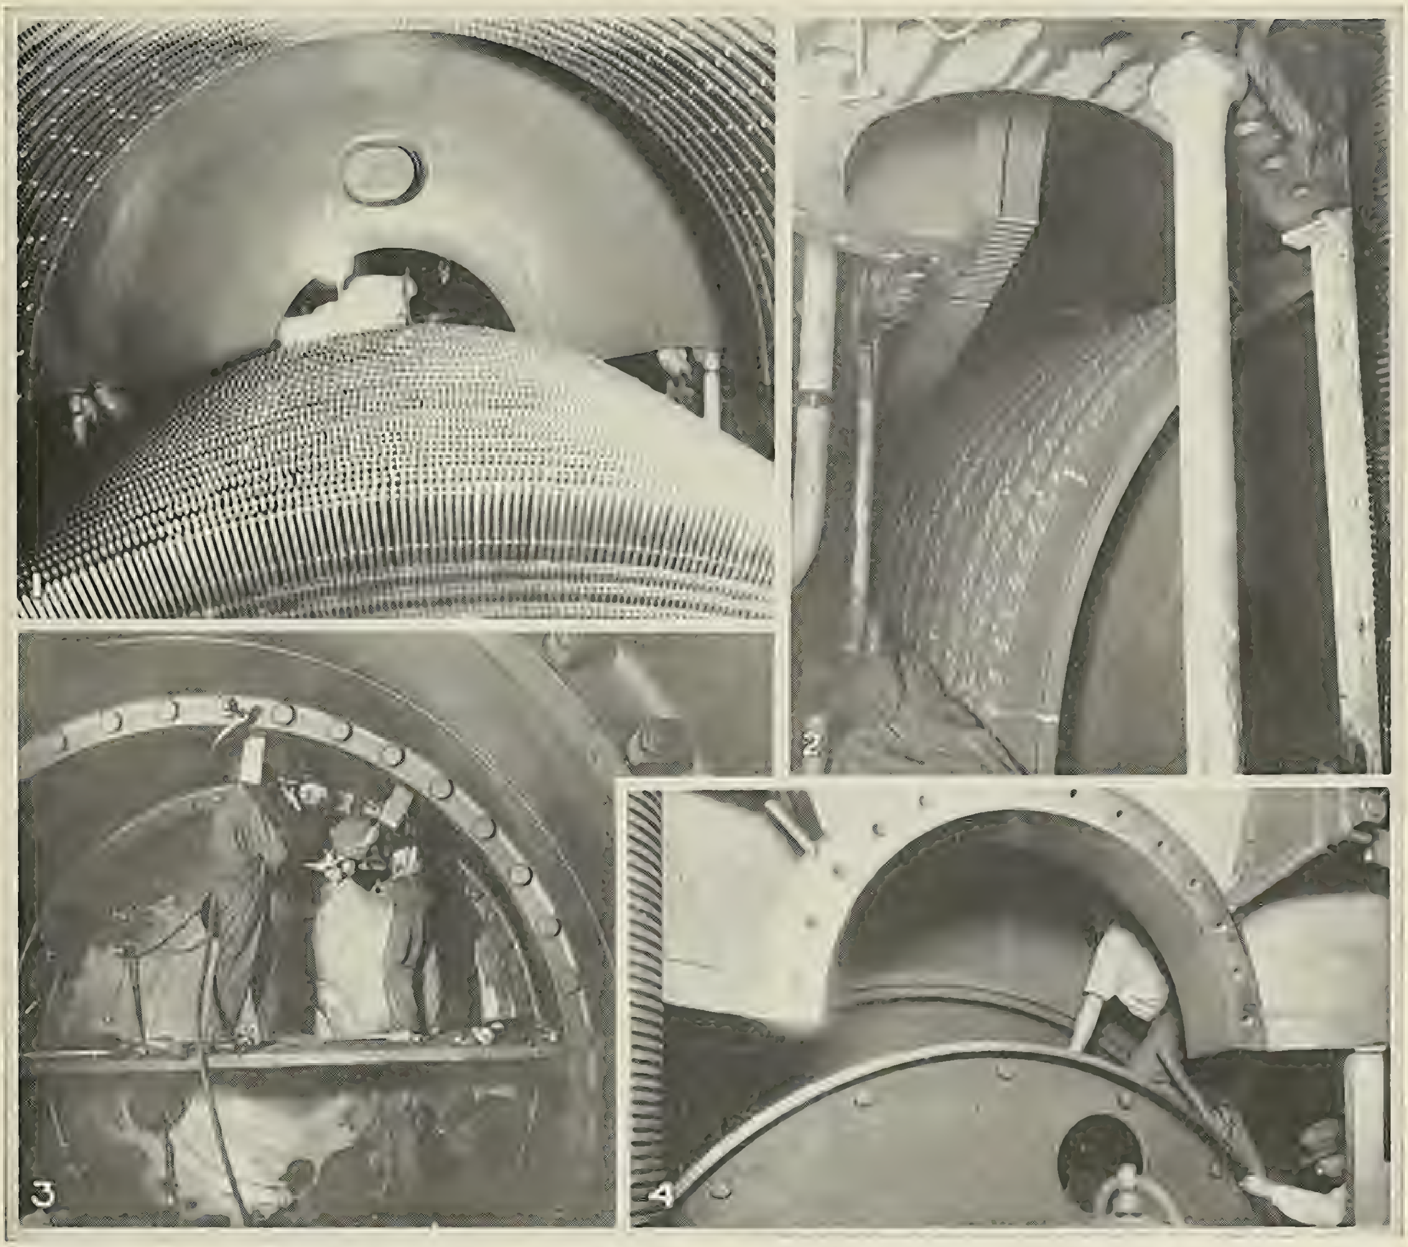
The manual fire alarm system consists of 45 alarm boxes from which an alarm can be sent in to the watchman's station. Electrical supervision is constantly maintained over both systems which announces the instant a circuit is broken or other trouble develops.

Watertight Door Alarm.—The watertight doors operated from the bridge, of which there are about 60, are equipped with contact makers which indicate on a diagram board on the bridge the position of each door. Alarm bells are located near each door, which are rung prior to the movement of the door. This alarm system forms a part of the hydraulic door control apparatus and prevents doors being operated without warning.

Clocks.—Electric clocks located in various public rooms and in many of the first class staterooms and suites are operated and controlled from the bridge. They can be simultaneously reset in either direction from the bridge as time changes occur during the trip. The control of the clocks is arranged on four circuits, there being an average of 35 clocks on each circuit.

Annunciator System.—An elaborate annunciator system covers the first and second class sections of the ship. Steward and stewardess buttons when operated in the various staterooms cause a lamp signal to operate at the nearest service station, giving the room number and class of service desired. This signal remains set until answered at the door of the stateroom from which the call was sent. At this point a reset button, operated by the steward or stewardess answering the call, releases the signal and restores the system to a condition ready for future calls.

About 80 of these section annunciators are installed, each covering ten rooms and being located centrally in the sections which they serve. The cases of the annunciators are of ornamental brass in a design which harmonizes with the surrounding joiner work. Additional annunciator systems are



Overhauling Main Turbines of the Leviathan: (1) Blading of Low Pressure Turbine; (2) Upper Casing of Low Pressure Turbine Raised, Showing Rotor; (3) Interior of Low Pressure Rotor; (4) Inspecting One of the Turbines

installed for the smoking rooms, swimming pool and bridge deck officers' quarters.

Bridge Equipment.—The apparatus on the bridge for the navigation and operation of the ship is as complete and modern as the science of shipbuilding can make it and covers engine telegraphs, installed in duplicate, revolution indicators, docking and anchor telegraphs, steering and rudder telegraph systems, whistle systems, iceberg danger signal system, submarine signal system and a life buoy system.

Sperry gyro compasses are installed in duplicate, with repeaters located at steering stations. A recorder is also installed for making a permanent record of all courses taken while under way.

Engine Room Equipment.—In the engine room are a number of special electrical signaling and recording systems all indicating at one central point. In this way the salinity of the feed water and the temperature of the fuel oil are indicated. A tableau board indicating the position of the various valves used to control the turbines is also installed and means are provided for transmitting the shaft speed from each of the four turbines to the boiler rooms, the engineers' log room and to the bridge.

Changes to Forced Draft System

The air supply to the after engine room is being doubled, with changes in the ventilating machinery and ducts. The duct to the forward engine room is divided, being made watertight to *F* deck and of light construction to the bridge deck, where two electrically driven multivane fans of 60,000 cubic feet of free air per minute are installed. The ventilation of the main galley is also being rearranged.

Steward's Department

With a full complement of passengers and crew the *Leviathan* will carry a total of 4,499 persons on her regular voyages.

To prepare the food for the restaurant, first class dining room, second and third class passengers, steerage, officers and crew there are seven complete galleys and four bakeries and the service of each is taken care of in a separate pantry. Each galley has its own storerooms, butcher shop and other facilities.

Galleys and Pantries

In design, arrangement and equipment the galleys and pantries will enable the operators of the vessel to offer to

ocean travelers a service superior to anything hitherto attempted afloat and unrivaled in any of the finest hotels ashore. Waste and labor will be cut down by the general adoption of electrically driven machinery in all the galleys and pantries and modern methods of administration will insure economical and efficient service in hot or cold climates.

Some idea of the extent to which modern electrically driven machinery is supplanting manual labor in these modern galleys and pantries is shown by the following equipment, supplied by the S. B. Sexton Company, Baltimore, Md., which is to be installed:

Restaurant Galley (on *A* deck, serving restaurant, winter garden, tea room and officers' dining room).—Six ranges, 1 bake oven, 2 grills, 1 ice cream maker, 1 meat and vegetable chopper, 1 bacon slicer, 1 potato peeler, 1 griddle, 1 waffle iron, 1 bread slicer, 1 coffee mill, 1 pastry mixer, 1 dishwashing machine (capacity 3,000 dishes per hour), 1 automatic toaster, all electrically operated.

First Class Galley (on *F* deck).—Two 8-fire island ranges, one 2-fire single range, 2 meat and vegetable choppers, 1 high powered mixer and whisking machine, 2 large capacity potato peelers, 4 60-gallon kettles, 12 2-section heavy duty vegetable steamers.

First Class Pantry (on *F* deck).—Six 20-gallon urns, 4 electric toasters, 1 electric coffee grinder, 2 electric dishwashing machines (each with a capacity of 15,000 dishes per hour), 1 double combination silver burnishing machine, electric bread slicers, griddles, ice cutting machine and knife cleaning machine.

In the first class dining saloon there are 48 electric plate warmers and in the restaurant 18 plate warmers.

Looking Aft from the Leviathan's Bridge, Starboard Side, Showing Material Being Placed on the Boat Deck by the 120-Ton Hammer Head Crane on the Fitting Out Pier Alongside

First Class Bread Making and Baking Rooms (2 on *F* deck).—Two heavy duty electric dough mixers (each of 2 barrels capacity), 2 electric ovens (each with a capacity of 180 one-pound loaves), roll dividing machine capable of producing 36 rolls at one operation, each roll of identical weight to the fraction of an ounce.

Pastry Room (on *F* deck).—One electric ice cream maker, 1 electric pastry mixer and whisking machine, 1 electric pie crust roller (capacity 25 crusts per minute), 1 electric griddle, 1 waffle iron (capacity 36 at one operation), 1 electric oven (capacity 60 one-pound loaves per hour).

Butcher Shop (on *F* deck).—Latest type, heavy duty electric meat chopper; electric bacon slicer and ice shaver.

Second Class Galley (on *F* deck).—One 6-fire range, four 50-gallon steam kettles, two 2-section vegetable steamers, 58-foot steam press and bainmarie.

Second Class Pantry (on *F* deck).—Three 20-gallon urns, electric toaster, griddle, coffee grinder, knife cleaning machine and dishwashing machine (capacity 15,000 dishes per hour).

Third Class Galley (on *E* deck).—One 4-fire island range, three 50-gallon kettles, one 800-pound capacity vegetable steamer, 1 heavy duty electric potato peeler, 1 electric vegetable and meat chopper.

Third Class Pantry (on *E* deck).—One electric dishwashing machine (capacity 6,000 dishes per hour), bread slicer, coffee grinder, knife cleaner, six 20-gallon coffee urns, 33-foot hot press and bainmarie.

Steerage Galley (on *D* deck).—One 3-fire, single front, coke-burning range, three 50-gallon kettles, one 800-pound capacity vegetable table steamer, electric heavy duty potato peeler.

Steerage Bakery (on *D* deck).—One latest type, 2-barrel capacity electric dough mixer, 1 heavy duty electric oven (capacity 180 one-pound loaves at one baking), two 20-gallon kettles.

Steerage Pantry (on *F* deck).—Three 30-gallon urns, electric bread slicer, coffee grinder and dishwashing machine (capacity 6,000 dishes per hour). An electric elevator connects the pantry with the galley three decks above.

Petty Officers' Galley (on *D* deck).—Special range, vegetable steamer, coffee boilers, electric coffee grinder.

Refrigerators

In addition to the main storage refrigerators on *J* deck for the preservation of perishable stores there are 20 service refrigerators distributed throughout the ship for the economical preservation of the proper foods at the required temperatures for the various classes of passengers. Twelve large refrigerators are for the first, second and third class passengers, while there are six others for restaurant supplies. To localize food for the crew and steerage passengers, four service refrigerators are installed forward on *D* deck and one on *E* deck. An ice-making plant, with a capacity of 6,720 pounds per 24 hours, is located on *H* deck. For easy handling the ice is made in 24-pound blocks and is sent from *H* to *F* decks by a special elevator. All new refrigerating apparatus is supplied by the Brunswick-Kroeschell Company, New Brunswick, N. J.

In order to facilitate serving passengers in the public rooms pantries have been constructed and fitted with all equipment necessary adjacent to the main social hall, winter garden, smoking room and tea room. For the convenience of passengers 43 ice water fountains supplied from brine cooled scuttle butts are distributed throughout the ship.

All pantries, service rooms, galleys and storerooms

throughout the ship are connected to the chief steward's office by telephones.

Steward's Supplies and Equipment

Supplies and equipment for the steward's department costing about $600,000 are being furnished by Gimbel Brothers, New York, in accordance with a contract awarded to this firm by the Shipping Board through its agents, Gibbs Brothers, Inc., New York. In all cases the equipment is the finest that can be procured and some idea of its quantity can be gained from the following items:

The linen for the first class dining saloon and restaurant and the sheets and pillow cases for the first class quarters is manufactured by McCrum, Watson and Mercer, Ltd., Milford, Ireland, and H. Matier and Company, Ltd., Belfast, Ireland, comprising about one-half of the linen required for the ship.

The linen for the second and third class passengers is manufactured by Hay and Robertson, Ltd., Dunfermline, Scotland, and H. Matier and Company, Ltd., Belfast, Ireland.

The silverware, supplied by the R. Wallace and Sons Manufacturing Company, Wallingford, Conn., totals more than 71,798 pieces of flat and hollow ware.

The china for the various dining rooms, manufactured by the Onondaga Pottery Company, Syracuse, N. Y., totals 102,000 separate pieces. The tea service sets for the restaurant and first class dining room are manufactured by Lenox, Inc., Trenton, N. J., making a grand total of 119,278 pieces of china.

The glassware, manufactured by the United States Glass Company, Pittsburgh, Pa., totals 48,084 pieces.

The equipment for the galleys and pantries, supplied by the Bramhall, Deane Company, New York, totals 23,000 pieces.

Other equipment, such as cotton sheets and pillow cases, steamer rugs, towels, etc., is being supplied in corresponding quantities by various manufacturers to the order of Gimbel Brothers.

Fresh Water Tanks

The fresh water is carried in the double bottom tanks and the former fresh water tanks aft of frame 150, including the two sections of the aft peak tank. In addition, two new fresh water deep tanks have been built aft. The boiler feed tanks have a total capacity of about 1,078 tons and the washing water tanks a capacity of about 1,667 tons. Two new vertical duplex pumps, 5¼ by 5 by 5 inches, have been installed for the drinking water system.

Ballast System

The former ballast system is being changed to provide a system for pumping ballast from all compartments used for the storage of oil fuel forward of frame 152 entirely independent of the oil handling, bilge or fresh water systems. The former ballast pumps are retained and one of the former ash ejector pumps has been connected to the ballast system.

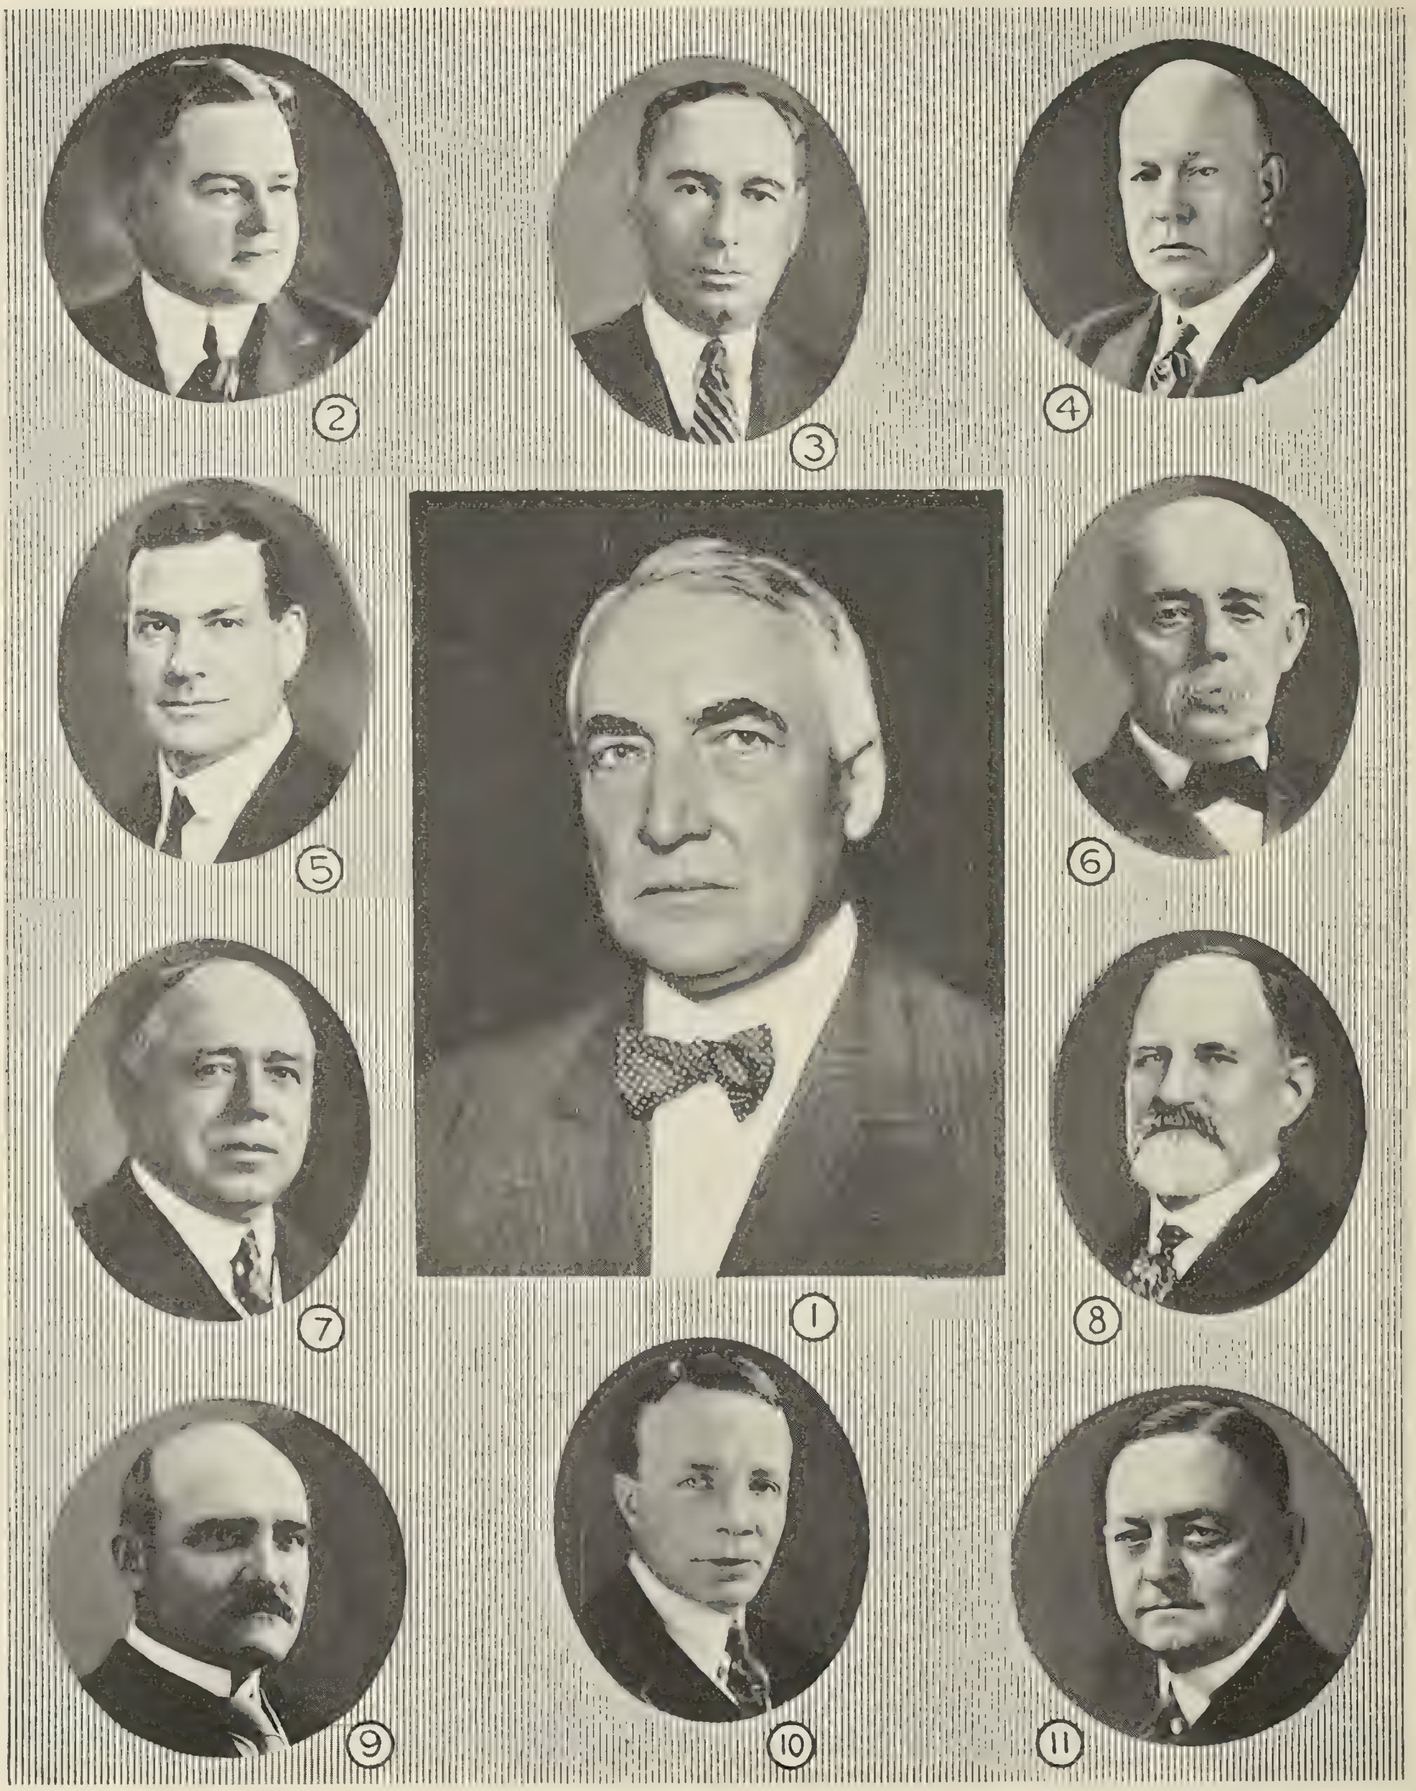
Lifeboats

The lifeboat equipment of the *Leviathan* will have a capacity for 4,750 persons. In all 76 lifeboats will be carried of which 40 with a total capacity for 2,466 persons will be reconditioned from the former equipment of the vessel.

Of the new lifeboat equipment, which is supplied by the American Balsa Company, Inc., Long Island City, N. Y., 22 are 30-foot metallic lifeboats, each with a capacity for 76 persons; 2 are 26-foot metallic lifeboats, each with a capacity for 50 persons; 3 are 30-foot metallic pontoons, each with a capacity for 66 to 70 persons, and 5 are 28-foot metallic pontoons, each with a capacity for 58 persons. In addition there are two 30-foot wooden motor lifeboats, built by the Newport News Shipbuilding and Dry Dock Company from plans supplied by the American Balsa Company, Inc., and equipped with engines by the Standard Motor Construction Company, Jersey City, N. J., and two 22-foot work boats. The motor lifeboats will be fitted with powerful wireless equipment and will be used for towing or conveying the other lifeboats.

The lifeboats will be handled by Welin quadrant davits of improved design with Welin electric lifeboat winches, and will be fitted with Mills releasing gear and Welin non-toppling blocks.

As the Leviathan Looked When She Left New York for Newport News for Her Transformation from a Troop Ship Into the Finest Passenger Liner Afloat



President, Statesmen of Both Parties, and Government Officials Who Are Leading Advocates for an American Merchant Marine

(1) Warren G. Harding, President of the United States; (2) Herbert Hoover, Secretary of Commerce; (3) Albert D. Lasker, Chairman of the Shipping Board; (4) Edwin Denby, Secretary of the Navy; (5) Senator Wesley L. Jones, Chairman of Committee on Commerce; (6) Congressman William S. Greene, Chairman of Committee on Merchant Marine and Fisheries; (7) Congressman George W. Edmonds, Vice-Chairman of Committee on Merchant Marine and Fisheries; (8) Senator Joseph E. Ransdell, President of National Merchant Marine Association; (9) Senator William M. Calder, Member of Committee on Commerce; (10) Colonel Theodore Roosevelt, Assistant Secretary of the Navy; (11) Senator Oscar W. Underwood, Democratic Leader of the Senate.

Officers of the American Marine Association

(1) Colonel E. A. Simmons, *Marine Engineering and Shipping Age,* president; (2) W. M. Wampler, The Ellcon Company and Coen Company, Inc., vice-president; (3) Robert B. Lea, Sperry Gyroscope Company, secretary; (4) H. C. Davis, Row and Davis, Engineers, Inc., treasurer.

Big Program Prepared for American Marine Week

Marine Exposition at Grand Central Palace Larger Than Ever—Naval Architects and Marine Engineers Convene November 8-9

THE second American Marine Week with its Marine Exposition, the thirtieth annual convention of the Society of Naval Architects and Marine Engineers and the meeting and participation of eighteen maritime organizations will be held at the Grand Central Palace, Lexington avenue and 46th street, New York City, during the week of November 4-11. This will be the greatest co-operative maritime event that has ever been staged in this country and it is bound to attract the attention of the entire nation to the necessity for an American merchant marine.

President Warren G. Harding will send a message which will be delivered in person by Honorable Edwin Denby, Secretary of the Navy, at the annual banquet of the Society of Naval Architects and Marine Engineers, which will take place at the Waldorf-Astoria on the evening of November 9. The President, as is well known, is heart and soul in favor of a strong American merchant marine, adequate in size to carry the greater portion of our commerce and to serve as a naval auxiliary in time of war or in a national emergency.

A fair idea of the quantity and quality of the exhibits at the Marine Exposition may be obtained by a perusal of the Directory of Exhibits which is published on pages 691 to 695 of this issue. The United States Coast Guard turbo-electric drive cutter *Modoc* will be open for inspection at the United American Lines pier 86, North River, at the foot of 46th street, from November 4 to 9, inclusive.

Program of "American Marine Week"

Saturday, November 4

OPENING DAY

4:00 P. M. Registration of delegates at Registration Booth in Main Lobby, Grand Central Palace, 46th street and Lexington avenue, New York, N. Y.

8:00 P. M. Formal opening of "Second Annual Marine Exposition" and "AMERICAN MARINE WEEK" under the auspices of the American Marine Association.

8:05 P. M. Address by Colonel E. A. Simmons, president, American Marine Association.

8:15 P. M. Address by Colonel Theodore Roosevelt, Assistant Secretary of the Navy.

9:00 P. M. Band Concert.

10:30 P. M. Closing Hour.

Monday, November 6

SHIP OWNERS' DAY

12:30 P. M. Public opening hour.
Registration of delegates at Registration Booth in Main Lobby, Grand Central Palace, 46th street and Lexington avenue, New York, N. Y.

2:00 P. M. Regular quarterly meeting, American Steamship Owners' Association, in association office, 11 Broadway, New York.

3:30 P. M. *"Ship Radio,"* by Arthur Batcheller, Chief Radio Inspector, Second District, Department of Commerce.

4:00 P. M. Official inspection of Marine Exposition, by the Technical Committee, American Steamship Owners' Association, William F. Gibbs, chairman.

NAVY NIGHT

8:30 P. M. *"The Navy,"* by Rear Admiral C. T. Vogelgesang, U. S. N.

9:00 P. M. Concert by Brooklyn Navy Yard Band.

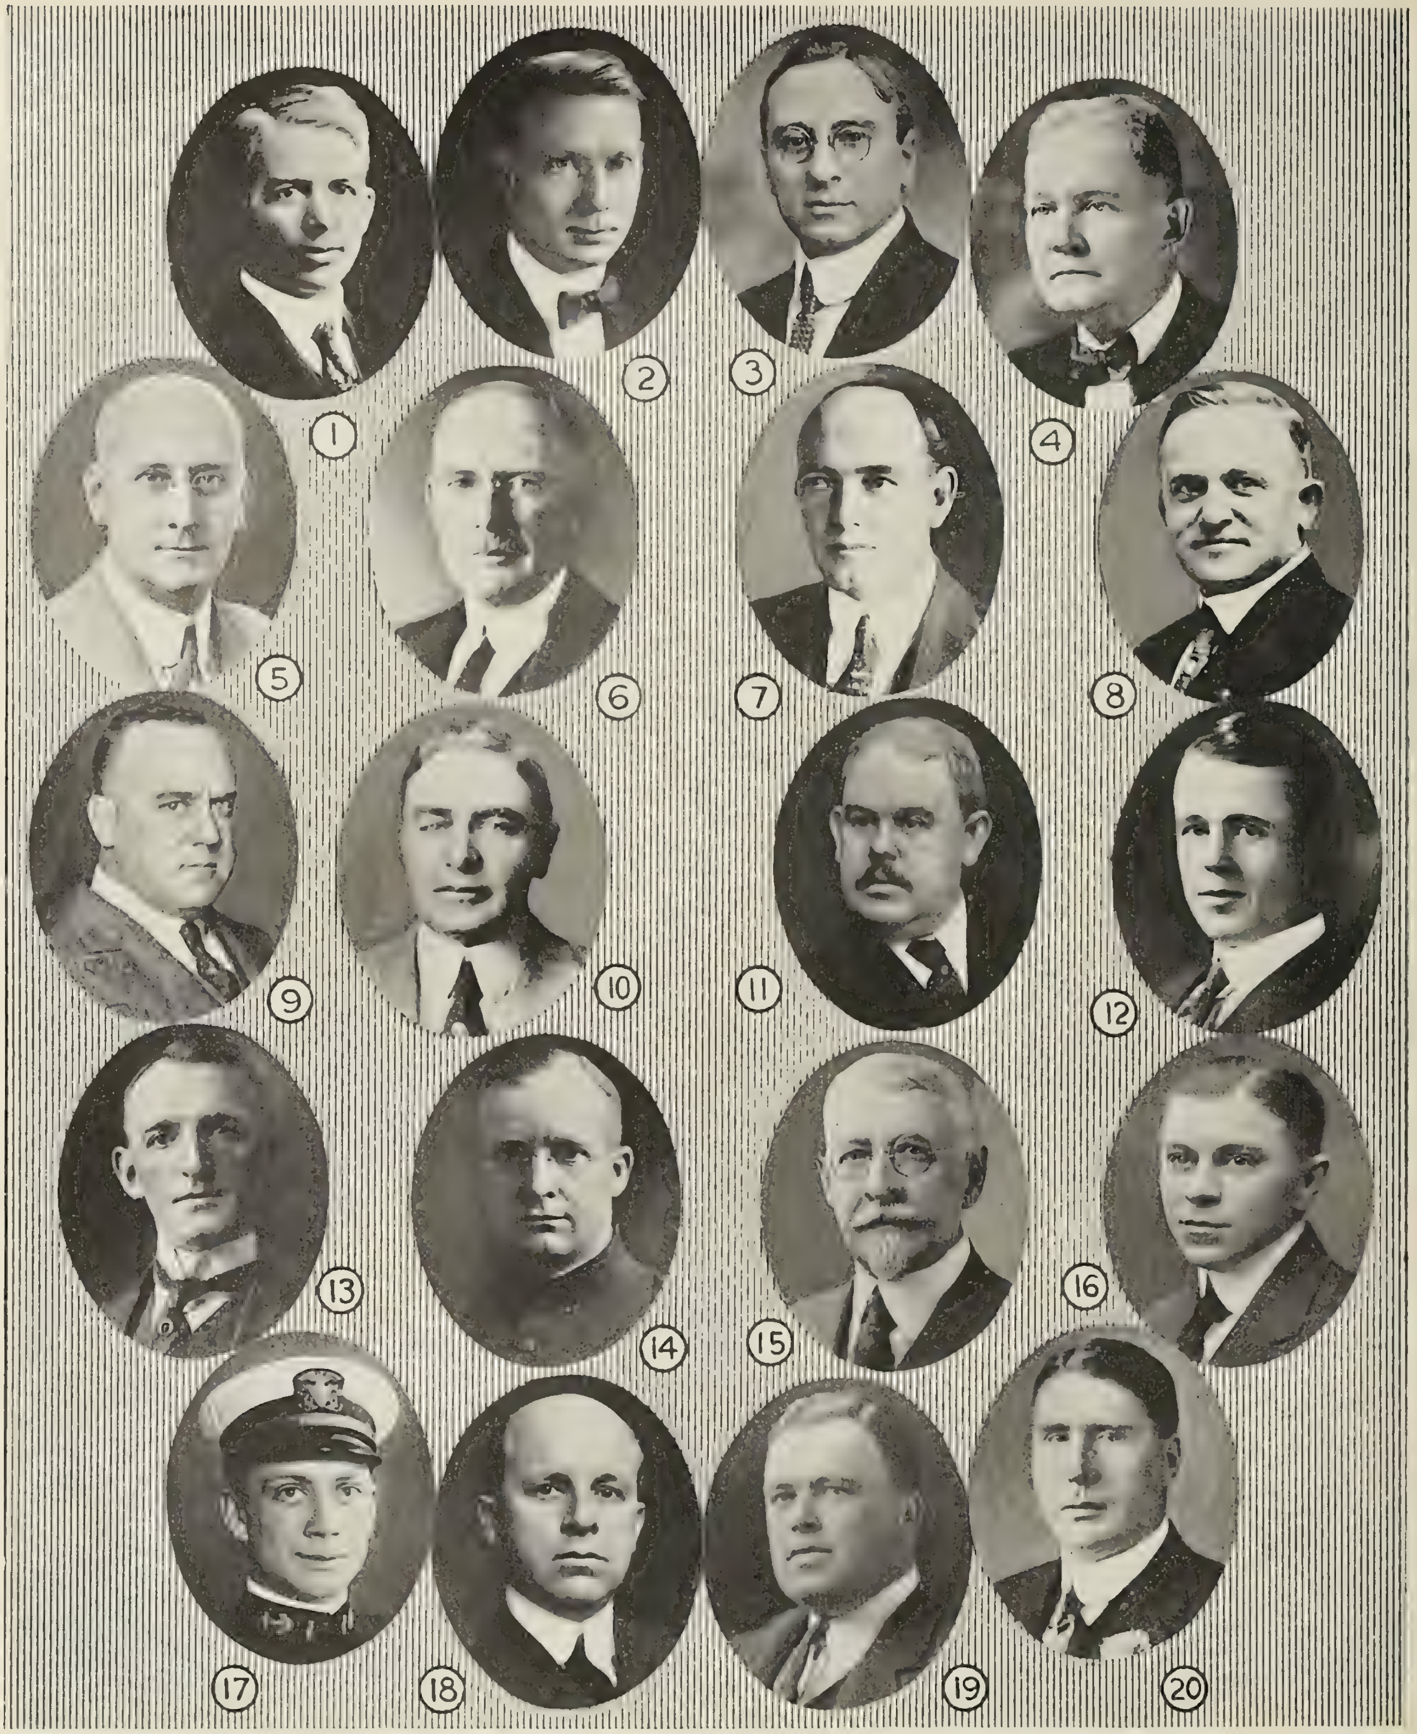
10:30 P. M. Closing Hour.

Tuesday, November 7

NEW YORK TOW BOAT EXCHANGE DAY

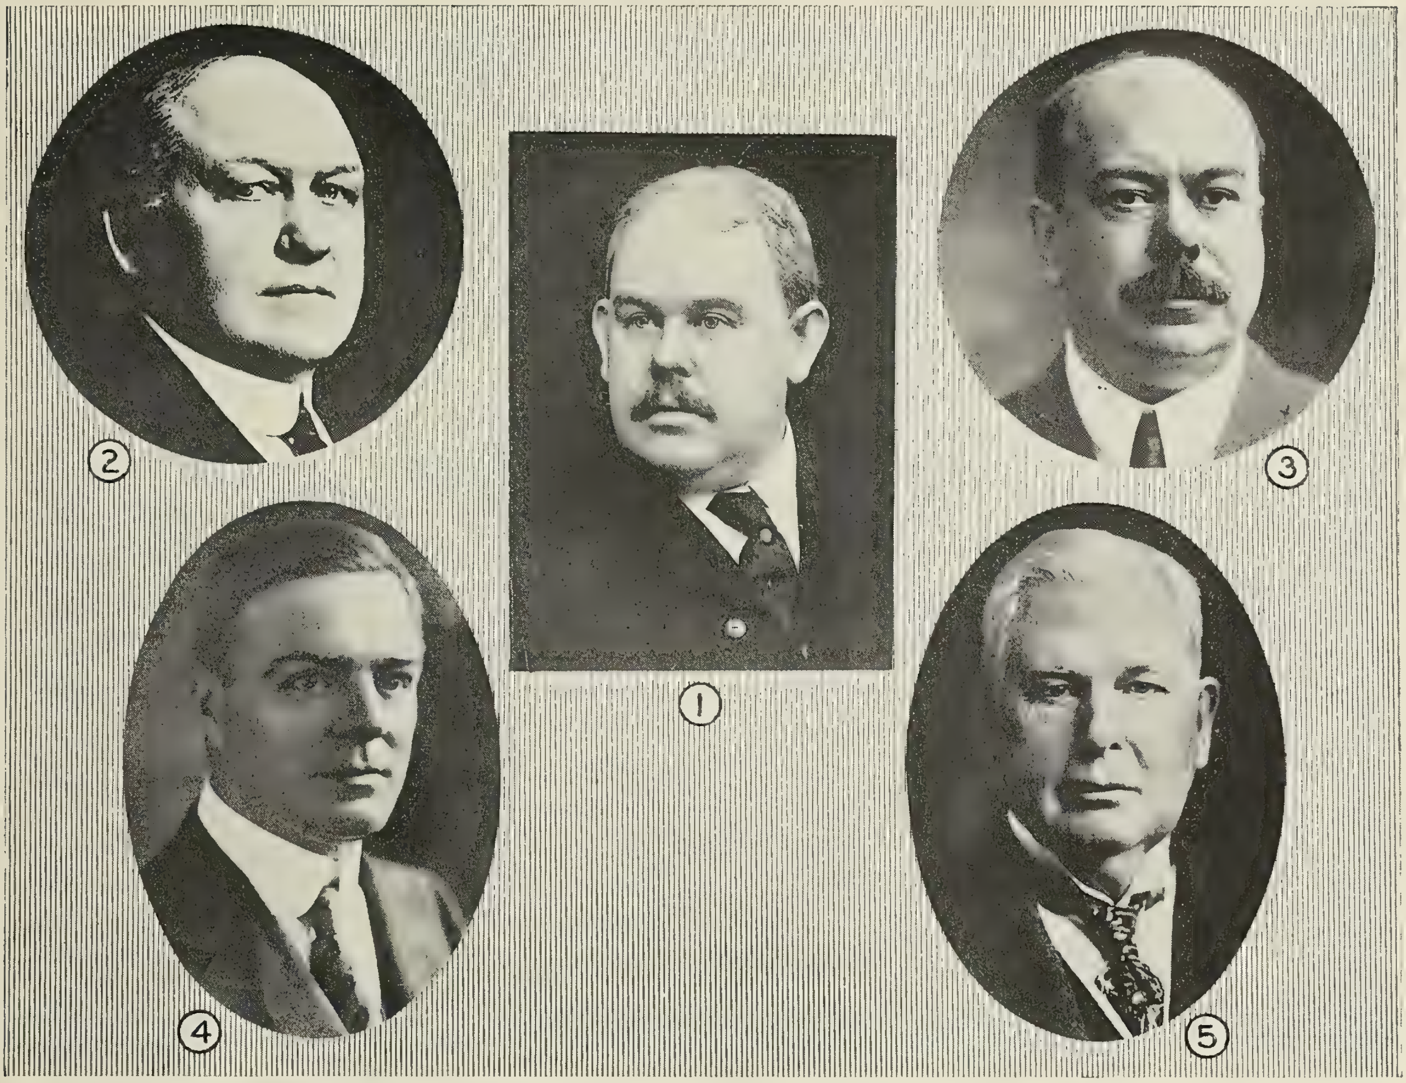
12:30 P. M. Public Opening Hour.
Registration of delegates at Registration Booth in Main Lobby, Grand Central Palace, 46th street and Lexington avenue, New York, N. Y.

2:30 P. M. Moving Picture, *"Tow Boating in New York*



Directors and Chairmen of Committees of American Marine Association

(1) H. L. Hibbard, Cutler-Hammer Manufacturing Company, executive committee; (2) W. A. Cather, Worthington Pump and Machinery Corporation, chairman, publicity committee; (3) M. L. Katzenstein, Worthington Pump and Machinery Corporation, executive committee; (4) Capt. W. H. Stayton, Baltimore Steamship Company, executive committee; (5) H. W. Adams, Jr., Scovill Manufacturing Company, executive committee; (6) W. P. Smith, William Cramp and Sons Ship and Engine Building Company, executive committee; (7) F. C. Bradbury, Crane Company, executive committee; (8) J. C. McQuiston, Westinghouse Electric and Manufacturing Company, executive committee; (9) Frank Hatch, Shephard Electric Crane and Hoist Company, executive committee; (10) Gardner Cornett, Pneumercator Company, executive committee; (11) W. M. McFarland, Babcock and Wilcox Company, executive committee; (12) G. W. Selby, Marine Decking and Supply Company, executive committee; (13) H. C. Davis, Row and Davis Engineers, Inc.,executive committee; (14) J. Hense, Northern Fire Apparatus Company, chairman, transportation committee; (15) W. A. Lake, Pantasote Company, chairman, entertainment committee; (16) K. W. Heinrich, Bethlehem Shipbuilding Corporation, executive committee; (17) W. S. Doxey, *Marine Review*, chairman, enrollment committee; (18) C. F. Scott, General Electric Company, executive committee; (19) Benjamin F. Neilds, Jr., National Malleable Castings Company, chairman, liaison committee; (20) H. F. Alexander, Pacific Steamship Company, executive committee.



(1) Captain Walter M. McFarland, President, Society of Naval Architects and Marine Engineers; (2) H. H. Raymond, President, American Steamship Owners' Association; (3) Charles H. Potter, President, Maritime Association of the Port of New York; (4) James L. Ackerson, President, Atlantic Coast Shipbuilders' Association; (5) Stevenson Taylor, President, American Bureau of Shipping.

Harbor," specially filmed for The New York Tow Boat Exchange, Auditorium, second floor, Exposition Hall.

3:00 P. M. Meeting of the Council of the Society of Naval Architects and Marine Engineers, Room 1101, Engineering Societies' Building, 29 West 39th street, New York, N. Y.

Ocean Officers' Night

8:00 to 10:30 P. M. National election returns broadcasted at 412 meters, by the Anacostia, D. C., station.

8:00 P. M. Smoker for masters, mates, pilots, engineers and radio telegraphers under the auspices of Ocean Officers' Conference, Auditorium, second floor, Exposition Hall.

10:30 P. M. Closing Hour.

Wednesday, November 8

Naval Architects' and Marine Engineers' Day

9:00 A. M. Private opening hour for members of the Society of Naval Architects and Marine Engineers.

10:00 A. M. Opening Technical Session of the Society of Naval Architects and Marine Engineers, President W. M. McFarland, presiding, Auditorium, second floor, Exposition Hall.

The following is the list of papers to be read and discussed at the Wednesday meetings:

1. *"Automatic Steering,"* by Elmer A. Sperry, Member.
2. *"Details of Naval Design from Jutland,"* by Commander Herbert S. Howard, C. C., U. S. N., Member.
3. *"The Application of Dyson's Method to Propellers of Ocean-going Merchant Vessels,"* by Edwin A. Stevens, Jr., Member.
4. *"Stresses on Vessels of the Great Lakes Due to Waves of Varying Lengths and Heights,"* by Professor Herbert C. Sadler, Member of Council, and Professor Anders Lindblad, Member.
5. *"A Study of the Wake of Certain Models by Means of a Current Meter,"* by Professor Edward M. Bragg, Member.
6. *"Some Experiments on Propeller Position and Propulsive Efficiency,"* by Rear Admiral David W. Taylor, C. C., U. S. N., Honorary Vice-President.

12:30 P. M. Public Opening Hour.
Registration of delegates at Registration Booth in Main Lobby, Grand Central Palace, 46th street and Lexington avenue, New York, N. Y.

Shipping Board Night

8:30 to 9:30 P. M. Concert, by the Washington Navy Yard Band, broadcasted at 412 meters, by the Anacostia, D. C., station.

9:35 P. M. *"The Navy After the Limitation of Arms Conference,"* by Captain Luke McNamee, U.S.N.; broadcasted at 412 meters, by the Anacostia, D. C., station.

10:30 P. M. Closing Hour.

Thursday, November 9

Naval Architects' and Marine Engineers' Day

9:00 A. M. Private opening hour for members of the Society of Naval Architects and Marine Engineers.

10:00 A. M. Second Day Technical Sessions of the Society of Naval Architects and Marine Engineers, President W. M. McFarland, presiding, Auditorium, second floor, Exposition Hall.

The following is the list of papers to be read and discussed at the Thursday meetings:

7. *"Efficiency in the Operation of Steamships,"* by Captain Daniel A. J. Sullivan.
8. *"A Sixteen Hundred and Fifty Horsepower Gasoline Fire Boat,"* by Arthur D. Stevens.
9. *"The Longitudinal Strength of Rigid Airships,"* by Professor William Hovgaard.
10. *"Machinery and Trials of the Passenger Ships—American Legion Class,"* by Robert Warriner, Member.
11. *"Standardization as Affecting the Shipbuilding Industry in the United States,"* by Ernest H. Rigg, Member of Council.
12. *"The Selection of the Best Kind of Propelling Machinery,"* by James L. Ackerson, Member.

12:30 P. M. Public Opening Hour.

Registration of delegates at Registration Booth in Main Lobby, Grand Central Palace, 46th street and Lexington avenue, New York, N. Y.

7:00 P. M. Reception at Waldorf-Astoria, 34th street and Fifth avenue, New York, N. Y., for members and guests of the Society of Naval Architects and Marine Engineers.

7:30 P. M. *"Ship Radio,"* by Arthur Batcheller, Chief Radio Inspector, Second District.

8:00 P. M. President Warren G. Harding's Message, delivered by The Hon. Edwin H. Denby, secretary of the Navy, at banquet of the Society of Naval Architects and Marine Engineers.

8:30 P. M. Address by Admiral R. E. Coontz, Chief of Naval Operations, U. S. N., broadcasted at 412 meters, by the Anacostia, D. C., station.

9:05 P. M. *"Navy Personnel,"* by Rear Admiral Thomas Washington, Chief of the Bureau of Navigation, U. S. N., broadcasted at 412 meters, by the Anacostia, D. C., station.

10:30 P. M. Closing Hour.

Friday, November 10

Department of Commerce Day

10:00 A. M. Annual meeting and election of officers of the American Marine Association, Auditorium, second floor, Exposition Hall.

Order of Business:

1. Reading of minutes of preceding meeting.
2. Report of Executive Committee.
3. General business.
4. Reports from district meetings of elections of members to Executive Committee.
5. Election of officers.

11:30 A. M. "Informal Conference on Standardization of Shipbuilding Equipment," under the auspices of the American Marine Association and The Department of Commerce, Auditorium, second floor, Exposition Hall.

12:30 P. M. Public Opening Hour.

2:30 P. M. Maritime Conference, Auditorium, second floor, Exposition Hall.

Speakers:

1. *"Duties of the Coast Guard,"* by Commander B. L. Reed, U. S. C. G.
2. *"The Lighthouse System of New York Harbor and the U. S. Coast Line, and Recent Improvements,"* by Geo. R. Putnam, Commissioner of Lighthouses, Department of Commerce. Illustrated by moving pictures.
3. *"The Relation of the Merchant Marine to Business,"* by Francis H. Sisson, Vice-President, Guaranty Trust Company.
4. *"Fuel Economy in Shipping Board Vessels,"* by Commander R. D. Gatewood, Director Division of Maintenance and Repair, United States Shipping Board.

National Merchant Marine Association Night

8:00 P. M. *"The Merchant Marine as a National Defense,"* by Captain William H. Stayton, President, Baltimore Steamship Company, Speakers' Forum, Exposition Hall.

8:30 to 9:30 P. M. Concert, by the Washington Navy Yard Band, broadcasted at 412 meters, by the Anacostia, D. C., station.

8:30 P. M. Motion picture, *"Tow Boating in New York Harbor,"* specially filmed for the New York Tow Boat Exchange, Auditorium, second floor, Exposition Hall.

9:35 P. M. *"What the Navy Does for Your Business and What It Costs You,"* by Captain L. M. Overstreet, U. S. N., broadcasted at 412 meters, by the Anacostia, D. C., station.

10:30 P. M. Closing Hour.

Saturday, November 11

Maritime Association Day

12:30 P. M. Public Opening Hour.

2:30 P. M. Maritime Conference, Auditorium, second floor, Exposition Hall.

1. *"The Value of the Tramp Steamship,"* by Chas. H. Potter, President, Maritime Association of the Port of New York.
2. Address, by Winthrop L. Marvin, Vice-President and General Manager, American Steamship Owners' Association.
3. *"The Ocean Officers,"* by Captain John F. Milliken, Secretary-Treasurer, Neptune Association.
4. *"Efficiency of Personnel,"* by Captain Reginald Fay, President, National Board Steam Navigation.

Armistice Night

8:30 P. M. *"Engineering and the Navy,"* by Rear Admiral J. K. Robison, Engineer-in-Chief, U. S. N., broadcasted at 412 meters, by Anacostia, D. C., station.

9:00 P. M. *"The Naval Air Service,"* by Rear Admiral William A. Moffett, Chief of the Bureau of Aeronautics, U. S. N., broadcasted at 412 meters, by Anacostia, D. C., station.

10:30 P. M. Closing Hour.

Directory of Exhibits at the Marine Exposition

Adams and Westlake Company, Philadelphia, Pa.—Joiner hardware, drapery hardware, furniture hardware, parcel racks, book racks, notice plates, sash locks, deck storm windows, electric fixtures for general superstructure lighting, including ceiling, wall and berth lights. Representatives: E. L. Langworthy, E. H. Stearns, C. S. Heller, H. Seip. Booth 75-A.

The Admiral Line, 17 State Street, New York.—Large outline map of the United States on which will be shown five trans-Continental railroad routes to the Pacific coast featuring the Admiral Line passenger service between Seattle, Victoria, Portland, San Francisco, Los Angeles and San Diego; in conjunction with the United States Shipping Board will present the Admiral Line trans-Pacific passenger service between Seattle and Victoria and Yokohama, Kobe, Shanghai, Hong Kong and Manila. Representatives, H. W. Rose, R. A. Wabraushek, A. C. Jones. Booth 311.

American Balsa Company, Inc., 305 Vernon Avenue, Long Island City, N. Y.—Ten-foot by 35-foot section of a ship's deck upon which is installed a set of Welin quadrant davits; a 26-foot steel nesting type lifeboat of the 1A class and a 26-foot steel standard 1A lifeboat chocked and nested between the davits as on board ship; Mills lifeboat releasing gear; Welin non-toppling blocks; Welin electric power winch. Representatives: H. F. Sailor, J. D. Andrew, Lewis Tanning. Booth 92.

American Car and Foundry Company, 165 Broadway, New York.—No. 3 two-electrode Berwick electric rivet heater; No. 3 one-electrode type "E" Berwick heater; 4-foot Berwick rod heater. Representatives: F. C. Cheston, W. M. Earl, J. S. Helt, D. B. Wallace. Booth 49-A.

American Engineering Company, Philadelphia, Pa.—Electric gypsy windlass. Representative: P. E. Kelly. Booth 89-B.

American Manganese Bronze Company, Homesburg, Pa.—A large bronze propeller blade; a medium sized solid propeller wheel of bronze polished; a demonstration of the ductility of the company's bronze as compared with iron and steel; test charts and photographs of installations of propeller wheels. Representatives: T. H. Addie, M. C. R. Spare, Mr. Nelson. Booth 2.

American Society of Marine Designers, 29 West 39th Street, New York.—Will represent the National Society at the Marine Show. Representative: C. C. Jacobson. Booths 228 and 229.

American Steel Foundries, McCormick Building, Chicago, Ill.—Models and photographs of standard types of ship's anchors, together with some views of specially interesting marine steel castings recently produced. A novel and successful improvement in the stockless anchor will also be shown. Representatives: A. Trevor Jones and J. T. Rowbottom. Booth 19.

Asbestolith Manufacturing Company, 1 Madison Avenue, New York.—Asbestolish for flooring, base, wainscoting, stair covering, etc., and for superior ship decking. Representatives: R. C. Burnside and assistants. Booth 64.

The Ashton Valve Company, 161-179 First Street, Cambridge 41, Boston, Mass.—Pop safety valves and relief valves; pressure and vacuum indicating and recording gages as well as testing outfits for gages and boiler test pumps; large steam whistles. Representatives: C. W. Buckelew, C. W. Ulrick and C. D. Motheral. Booth 21.

The Babcock & Wilcox Company, 85 Liberty Street, New York.—Full size sectional model of 4-inch merchant marine boiler; various sections of boiler parts, valves, fittings and tools; mechanical oil burners in full size mounted models; concentration indicator in operation. Representatives: J. H. King, C. W. Middleton, A. Ross Mackay, George H. Daniels, T. B. Stillman, John Coleman, E. A. Colson. Booth 42.

Beaver Tile Corporation, 442 West 42nd Street, New York.—Cork composition tile; natural cork tile for passages, lobbies, public rooms and staterooms. Representatives: Messrs. Newell, Hendrickson and Nason. Booth 43.

Bethlehem Shipbuilding Corporation, Ltd., Bethlehem, Pa.—Bethlehem-Weir turbo feed pump; Bethlehem-Weir reciprocating pump; complete Bethlehem (Dahl) mechanical oil burning system, including pumps, heaters, etc. Representatives: G. E. Lawrence, F. K. Steinrock, G. W. Grove, A. E. Fraser, G. H. Dillon, A. V. Reynolds. Booth 70.

Bramhall Deane Company, 261 West 36th Street, New York.—Representative: W. F. Wright. Booth 77-B.

Briggs Engineering Works, 227 24th Street, Brooklyn, N. Y.—Complete oil firing equipment. Representatives: C. N. Wheeler, H. W. Kuppinger. Booth 103.

Brunswick-Kroeschell Company, New Brunswick, N. J.—Two-ton refrigerating capacity marine type Brunswick ammonia compressor, direct connected to steam engine; ½-ton refrigerating capacity marine type Brunswick ammonia compressor, direct connected to steam engine; 2-ton refrigerating capacity marine type Kroeschell carbonic anhydride compressor, direct connected to steam engine; 1-ton refrigerating capacity marine type Brunswick ammonia compressor, direct connected to 3 horsepower electric motor; small Brunswick ammonia compressor cut down to show interior construction. Representatives: W. O. Whitney, W. Carpender, Booth 34.

Chase Metal Works, Waterbury, Conn.—Samples of all the sizes of copper tubing furnished to the S. S. *Leviathan*; Admiralty condenser tubes; Chamet bronze; brass rod; tubing, wire and sheet; a Balopticon which will explain by photographs and titles the Chase processes of making condenser tubes; new book on condenser tubes explaining their manufacture and specifications. Representatives: R. Chase, Capt. Gleason, D. K. Crampton, C. B. Smith, J. F. Giffen. Booth 90-A.

Coen Company, 50 Church Street, New York.—Oil burning equipment completely piped up ready for operation; firing fronts, including a forced draft Scotch boiler front, also a new large air register front for natural or induced draft; easy cleanable oil heaters; duplex oil strainers both for oil suction, discharge and for Diesel engine work; steam atomized burners with furnace decking for a flat flame burner, also the "Safety First" lighting torch; Type "A" burner complete with holder. Representatives: W. M. Wampler, F. Hall, H. B. Chamberlain, F. S. Harper. Booth 57.

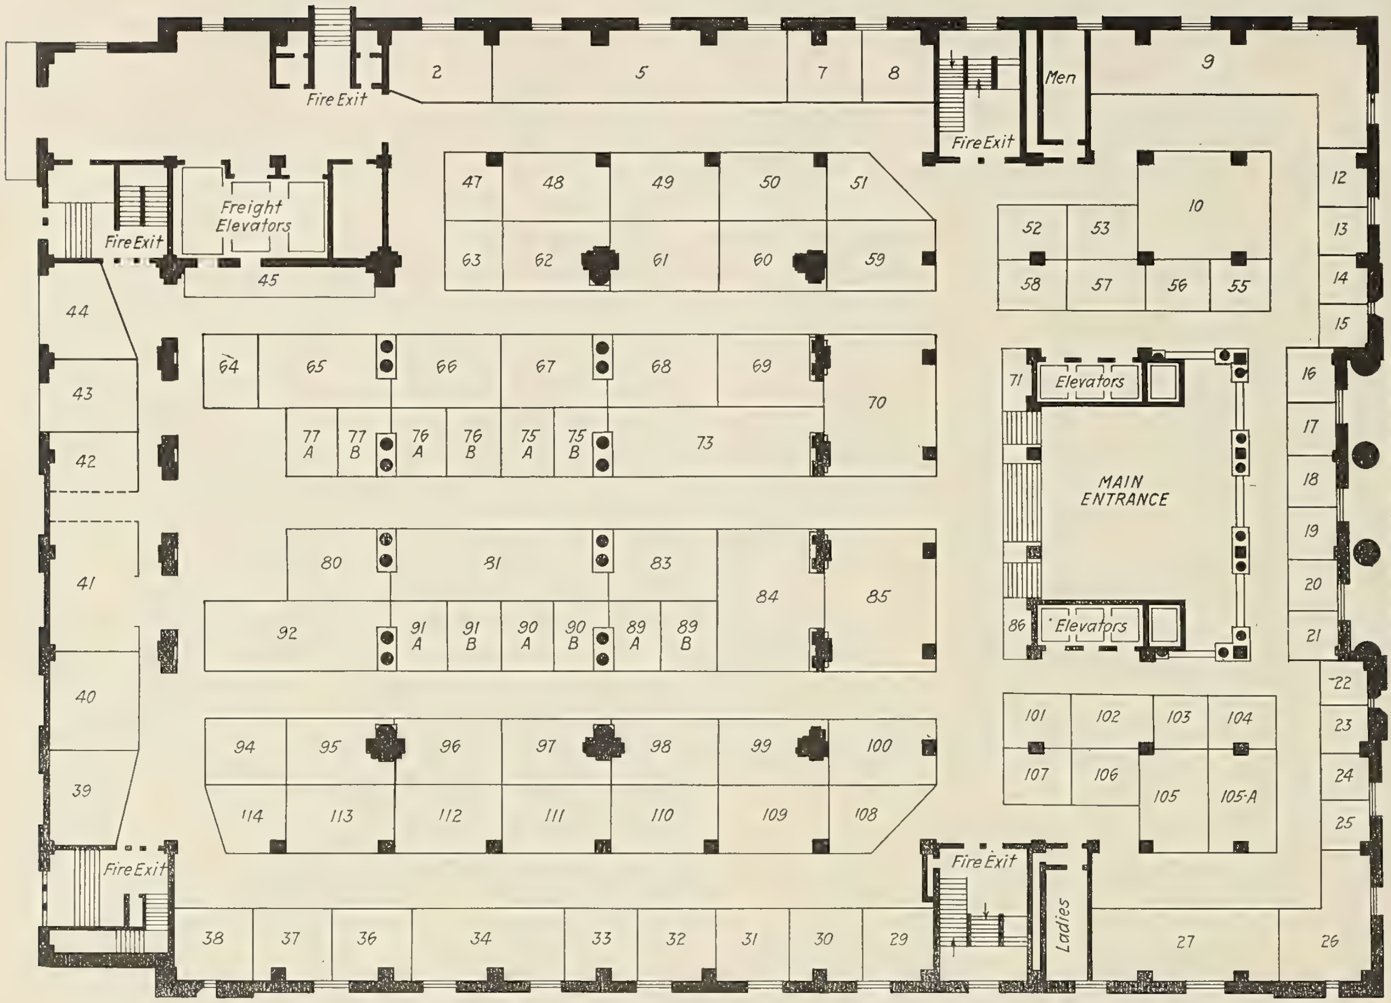
Jas. A. Coffey Engineering Corporation, 1416 Broadway, New York.—Asphalt floors for interior and exterior decking; asphalt calking putty. Representatives: J. A. Coffey, L. Coffey, Miss Adele Eckstein. Booth 25.

The William Cramp & Sons Ship & Engine Building Company, Richmond and Norris Streets, Philadelphia, Pa.—A large Parsons' manganese bronze propeller, 11 feet 4 inches diameter, weighing about 12,000 pounds, this wheel being machined complete including the planing of the driving faces of the blades to a true helical surface and designed to transmit about 23,000 horsepower; complete model of the steamship *Santa Paula;* half size model of a lifeboat fitted with the Hunt releasing device; ingots of Parsons' manganese bronze, Parsons' white brass and Cramp's Diesel engine babbitt; Parsons' manganese bronze welding rods, Cramp's aluminum solder and Cramp's cast iron solder; spiral gear wheels of Cramp's super-strength bronze for Diesel engines; framed photographs of Cramp's marine Diesel engines, Burmeister & Wain type. Representatives: Courtland D. Cramp, I. B. Ashenfelter, W. P. Smith, Carroll S. Smith, C. R. Peterson and J. C. Shaw. Booth 73.

Crandall Engineering Company, 100 Border Street, East Boston, Mass.—Demonstration model of a longitudinally-trussed floating dock and a working model of the Crandall railway dry dock together with photographs of dry docks now in operation. Representatives: R. H. Lindgren and J. Stuart Crandall. Booth 38.

Crane Company, 836 South Michigan Avenue, Chicago, Ill.—The largest brass gate valve made. Representatives: G. E. Barker, E. Morgenthal, T. H. Ireland, J. C. Cole, F. C. Bradbury. Booth 68.

Crane Packing Company, 59 Park Place, New York.—"John Crane" flexible metallic packings, superheat packings, metal-



Main Floor Plan of Marine Exposition, Grand Central Palace, Lexington Avenue and 46th Street, New York

lic condenser packing. Representatives: J. N. Walton, E. M. Roberts, C. W. Bryden. Booth 304.

Department of Commerce, Washington, D. C.—*Foreign and Domestic Commerce*: Maps showing trend of foreign trade, etc., books, monographs, charts and other publications on foreign trade; posters. Representatives: R. E. Hutchinson, E. G. Gregg.

Bureau of Standards—The principal exhibit of the Bureau of Standards will be that of radio equipment, which will give an excellent example of the Bureau's development work. The Bureau will also exhibit its fog signal model and a collection of publications of direct concern to maritime interests.

Lighthouse Service: Flashing lens, illuminating and revolving, as in service; fog signal automatic siren and horn; lens lantern; post lantern; electric clock and flasher; lighthouse Service pennant; radio fog signal system; radio compass for use with radio fog signal; radio fog signal chart; charts of New York harbor. Representatives: J. T. Yates and assistants.

Bureau of Navigation—A complete ship radio installation, Kolster decremeter and other instruments used in connection with the inspection of radio stations, and the omnigraph used in connection with the examining of operators; if possible, arrangements will be made to examine applicants for radio licenses at the booth; if not, Mr. Arthur Batcheller, Radio Inspector, who will be in charge of the exhibit, will arrange for the examination of applicants at the Custom House, New York. Representative: W. D. Terrell.

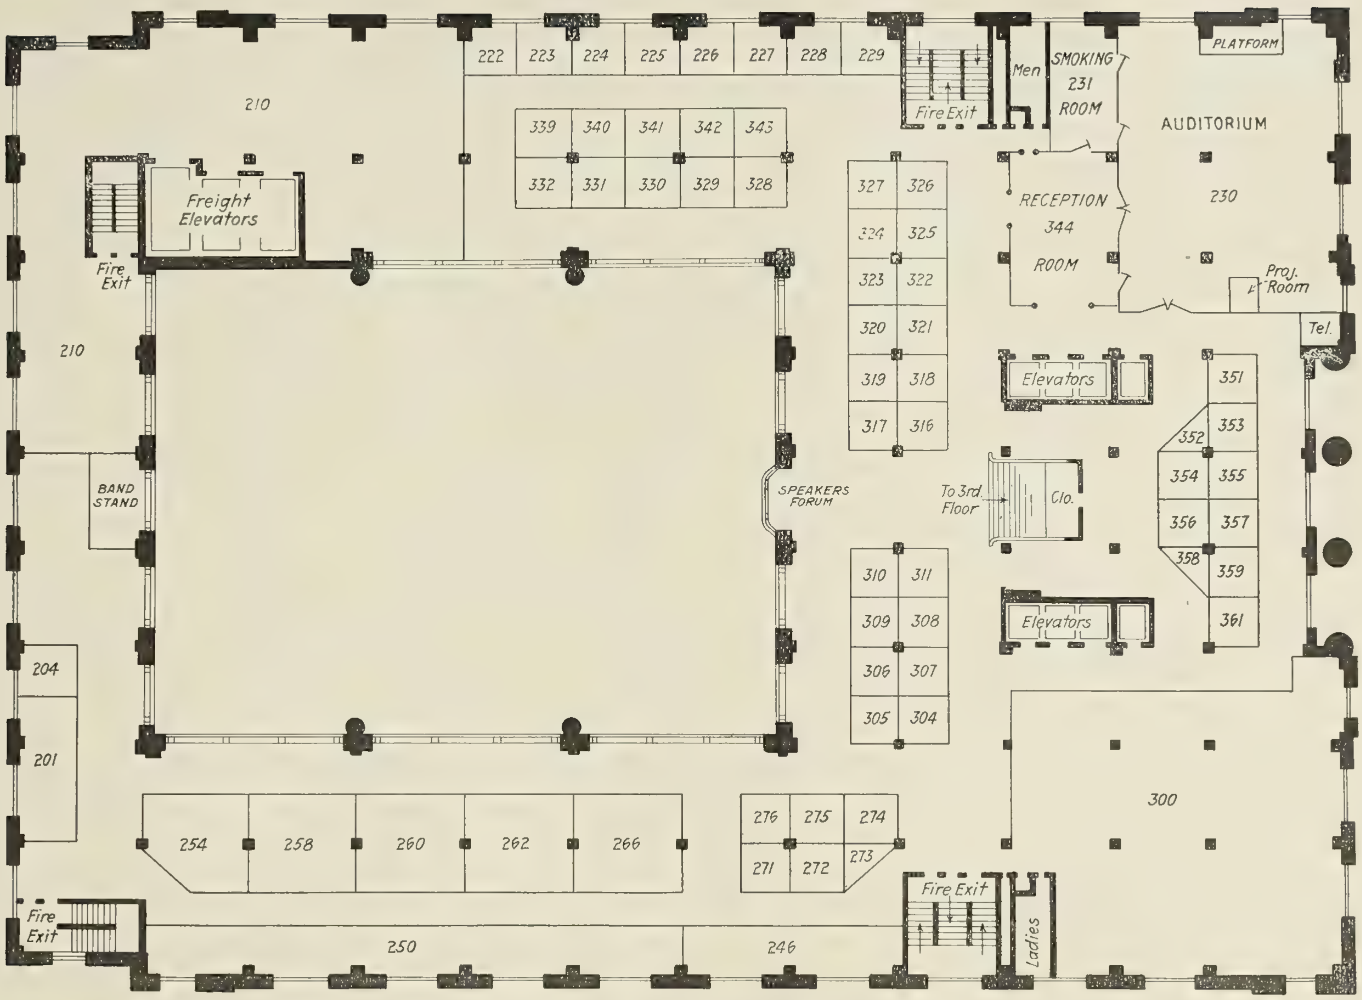
Coast and Geodetic Survey—A complete set of charts, over 600 in number, covering the territorial waters of the Atlantic, Pacific and Gulf coasts of the United States, Porto Rico, Hawaii, Panama, Virgin Islands, Guam and the Philippines, a total length of shore-line in excess of 100,000 miles; fifteen volumes of sailing directions, or coast pilots, for all the coastal and inside routes covered by the coast survey charts, "Tide and Current Tables," for all navigable tidal waters and for all currents in territorial waters; special publications on miscellaneous subjects related to navigation; diagrams and photographs illustrating methods and results of the survey's operations. Representative: R. L. Faris.

Steamboat Inspection Service: Shoulder line carrying gun with full equipment; twenty-two-foot lifeboat with full equipment for ocean service; set of turning out davits for lifeboat; model of Engelhardt lifeboat; model of catamaran life raft; model of Carley life float; adult life preserver for ocean service; adult life preserver for river and harbor service; child life preserver; life preserver in section; line carrying gun with full equipment; cork ring buoy with water light; ring buoy not covered; American fire tank containing liquid and buckets; soda and acid fire extinguisher; soda and acid fire extinguisher, sectional; deep sea sounding machine; section of hose with nozzle, gage and relief valve; dead weight gage tester; air pump and gage for testing air tanks of lifeboats; set of steel stamps for stamping boiler plate; micrometer for calipering boiler plate; set of steel test coupons; set of welding coupons; each of license forms; detecting and control cabinet for fire; safety valve, sectional; fog horn, mechanical; fusible plugs. Representative: F. P. Noel. Booth 210.

Diamond Power Specialty Corporation, Detroit, Mich.—Display of two new types of marine soot blowers, Model BBM for Scotch marine boilers and Model G-2 M for use with revolving soot blower elements on marine watertube boilers; working models of its Model B rear end blower for Scotch marine boilers and of its Model G-2 and Valve-in-Head soot blowers for watertube boilers. Representatives: L. W. Nones, A. W. Homan and Mr. Crawford of New York and Robert June of Detroit. Booth 63.

O. M. Edwards Company, Inc., Syracuse, N. Y.—Window balances, locks and anti-rattling devices for sash; interior steel furniture and trim. Representatives: E. F. Chaffee, Harold Edwards, J. J. Edwards, A. J. Horgan. Booth 56.

Ehret Magnesia Manufacturing Company, Valley Forge, Pa.—Ehret's 85 percent magnesia pipe and boiler coverings, 85 percent magnesia plastic, powdered magnesium carbonate. Representatives: R. F. Leonard, A. A. Pfeiffer, J. W. Quinn. Booth 75-B.



Mezzanine Floor Plan of Marine Exposition, Grand Central Palace, Lexington Avenue and 46th Street, New York

Electric Storage Battery Company, 18th and Allegheny Avenues, Philadelphia, Pa.—Exide batteries for marine service; wireless, lighting, gyroscope and compass service, motor boats and speed boats, and ignition; also Exide "Ironclad" batteries for industrial trucks and a complete submarine cell; complete marine wireless switchboard. Representatives: Mr. Folk, Mr. Gay, Mr. Fuller, Mr. Wright, Mr. Kulberg, and Mr. Norris. Booth 356.

The Ellcon Company, 50 Church Street, New York.—White porcelain enameled stanchions; Aero metal fittings; window curtains and fixtures for passenger vessels; ball bearing door hangers; flexible reinforced metal hose for oil burning vessels; ladder for engine and fireroom gratings fitted with safety step treads to prevent slipping. Representatives: W. M. Wampler, G. H. Ord, C. A. Koenig. Booth 53.

Exeter Machine Works, 30 Church Street, New York.—Rotary pumps suitable for the following marine service: Cargo, ballast, fuel oil transfer, lubricating oil, sanitary and fresh water. Representative: C. G. Holmquist. Booth 77-A.

Fire Detecting Wire Corporation, 2 West 45th Street, New York.—Automatic fire alarm apparatus. Representatives: C. Van Zandt, C. Peterson. Booth 276.

Foster Marine Boiler Corporation, 111 Broadway, New York.—Catalogs and test data describing the operation of the Foster marine boiler on over 135 ships; also literature describing the new Foster marine economizer which is the latest development in fuel conservation for marine boilers. Representatives: J. J. Nelis and John Kilfeather. Booth 106-A.

General Electric Company, Schenectady, N. Y.—The rotating element of a 3,000 horsepower reduction gear, less the low speed gear, such as is used in ships equipped with geared turbine drive; model of the low speed gear and an actual spring thrust bearing used in propulsion service; control panels built for the Golden Gate line of Diesel engine electric ferryboats and the turbine electric boats for the San Francisco-Oakland line in San Francisco harbor; motors for driving ship's auxiliary apparatus; 10 kilowatt steam engine driven generating set and control panel; searchlights; complete arc welding outfit in operation. Representatives: W. J. Day, E. K. Henley, C. H. Giroux, G. E. Young, W. J. Belanger. Booth 5.

Gimbel Brothers, 33rd Street, New York.—China, glass, silverware, linens, sheets, pillow cases, towels, blankets, steamer chairs, books and other items to be furnished under contract to the S. S. *Leviathan* Representatives: E. F. Quinn, J. J. Matthews, J. J. Lynch. Booth 83.

Griscom-Russell Company, 90 West Street, New York.—Reilly submerged type evaporator, self-scaling; G-R automatic feeder which maintains a constant water level in the evaporator shell; the G-R automatic vapor pressure control valve; the special G-R drainer for keeping the coils clear of water, as well as the other standard fittings; G-R type C expansion joint. Representatives: R. Colston and A. R. Hoffman. Booth 60.

Hooven-Owens-Rentschler Company, Hamilton, Ohio.—Hamilton Damara piston rings; marine engine parts; pictures of the various Hamilton marine engines; views of the plant and of ships driven by Hamilton marine engines. Representatives: G. A. Rentschler, Jr., H. Greger, H. A. Smith, F. L. Hummel. Booth 18.

Hyde Windlass Company, Bath, Maine.—Electric steering gear in operation; electric telemotor recently perfected. Representatives: R. E. Ross, F. L. Andrews, C. E. Paine. Booth 33.

International Nickel Company, 67 Wall Street, New York.—Monel metal and nickel in basic and commercial forms; power plant applications; various applications to marine uses. Representatives: G. A. Wotherspoon, E. A. Turner, A. Muller-Thyme. Booth 76-B.

Keasbey & Mattison Company, Ambler, Pa.—Working steam coil with various types of insulating materials applied and suitable instruments on these to show the actual cutting down in temperature by the use of these insulations; charts will show the actual saving in B. T. U. through the use of

the several grades of insulation. Representative: L. L. Barrett. Booth 47.

Kingsbury Machine Works, 4320 Lackawanna Street, Frankford, Philadelphia, Pa.—Kingsbury thrust bearings (six exhibits): self-lubricating bearings of two types; turbine bearings; large equalizing bearing; air-lubricated bearing; thrust shoe for United States airplane carrier (largest yet built). Representatives: A. Kingsbury, H. A. S. Howarth, W. T. Holman, Nelson Ogden. Booth 101.

Lee & Simmons, Inc., 44 Whitehall Street, New York.—Models of barges used in the transportation business in the port of New York; models and pictures showing the evolution from the old sail lighter to the barges of the present day. Representatives: D. T. Lamond, G. J. Lutz, R. O. Wilson, C. C. Miller, J. P. Heuer, W. G. Conners, H. F. Carls. Booth 31.

Leviathan Model.—Booths 81 and 82.

Luckenbach Steamship Company, 44 Whitehall Street, New York.—Representative: A. B. Townsend. Booth 316.

Lunkenheimer Company, Cincinnati, Ohio.—Valves, lubricators, oil cups, grease cups, whistles, boiler mountings and similar engineering specialties; the line of valves consists of one for practically any purpose and made of either bronze, iron, steel or a special alloy. Representatives: W. A. Reynolds, J. E. Cooper, H. Burger. Booth 99.

Marine Decking & Supply Company, 116 North Delaware Avenue, Philadelphia, Pa.—American Lit-O-Sil-O decking; American Lit-O-Sil-O flooring; Madesco tackle blocks, sheaves, shackles, etc. Representatives: W. L. Peebles, J. S. Tyler, E. P. Jewell and G. W. Selby. Booth 96.

Marine Engineering and Shipping Age, Woolworth Building, New York.—Marine Engineering and Shipping Age. *The Boiler Maker,* "Shipbuilding Cyclopedia," "Practical Marine Engineering," "Laying Out for Boiler Makers" and marine books. Representatives: Colonel E. A. Simmons, Henry Lee, C. R. Mills, R. V. Wright, George Slate, F. B. Webster, H. H. Brown, L. S. Blodgett, W. Z. Gardner, H. B. Bolander, J. A. Miller, B. L. Dombrowski, R. F. Duysters, N. C. B. Fowles, J. E. Anderson. Booth 51.

Marine Works, Inc., 31 Coenties Slip, New York.—Marine kitchen and pantry outfits; sundry labor saving machines for food service; crockery; glassware, etc. Representative H. Cunningham. Booth 204.

Maritime Association of the Port of New York, 78 Broad Street, New York.—Bureau of information from a direct wire from the Maritime Exchange, giving complete news of ship disasters, sailings, movements of vessels in New York harbor and principal ports in the world; reproduction of bulletin board used on the exchange, giving entrances and clearances from the port of New York; numerous ship models. Representative: H. J. Mostyn. Booth 225.

Mercantile Specialty Company, 11 Broadway, New York.—Smithson safety porthole, smoke indicator and fuel economizer; the Keesey bridge and engine telegraph. Representative: H. G. Mullen. Booths 306 and 307.

Munson Steamship Line, 67 Wall Street, New York.—Pictures, posters, literature and reproduction of the interior of a steamer. Booth on second floor with Shipping Board exhibit.

Mustor Manufacturing Company, Grand Central Terminal, New York.—Interlocking rubber tiling; corrugated and perforated rubber mats and matting; patented oval split core and flap ring packings; high pressure sheet packings; pump valves. Representatives: G. F. Mustor, Walter S. Mustor. Booth 46-A.

National Merchant Marine Association, Washington, D. C.—Literature published by the Association. Representatives: A. H. Battey, Mr. MacDonald. Booth 311.

The National Malleable Castings Company, Cleveland, O.—Various sizes of Naco chain, shackles, both connecting and anchor, and swivels. Representative: B. Nields, Jr. Booth 58.

National Meter Company, 229 Broadway, New York.—Oil and water meters, high, low and medium pressures, for all services. Representative: G. D. MacVeagh. Booth 77-B.

Natural Carbonic Gas Company, Newark, N. J.—Cylinders containing carbonic gas—CO_2, for refrigerating purposes. Representatives: T. P. Arnold, P. E. Fay and C. A. Nichols. Booth 305.

Nautical Gazette, 20 Vesey Street, New York.—*Nautical Gazette* and various shipping books. Representative:: J. F. Loe. Booth 350.

Newport News Shipbuilding & Dry Dock Company, Newport News, Va.—Pictures illustrating the development of the plant; model of the S. S. *Leviathan* which is being reconditioned by the Newport News Company is to be located in an adjacent booth. Representative: J. P. Kiesecker. Booth 80.

New Process Chemical Company, 114 Liberty Street, New York.—Marine glue; anti-corrosive paint; anti-fouling paint; canvas paint; copper paint; tri-bituma coatings; linoleum cement. Representatives: A. Schlueter, L. Strawser, W. Gutterson, M. E. Granier. Booth 342.

New York Journal of Commerce.—Representative: P. Moneypenny. Booth 310.

New York Marine News Company, 26 Water Street, New York.—*The Marine News.* Representatives: H. J. Harding, A. H. Addoms, H. Palmer, T. Olsen, G. Weiss, C. Files and G. F. Howell. Booth 86.

New York Tow Boat Exchange, 11 Moore Street, New York.—Will demonstrate facts about the towing industry; models of tow boats; a motion picture of the towing industry entitled "Full Speed Ahead." Representative: C. A. Mason. Booth 343.

New York Tribune.—Booth 317.

Northern Fire Apparatus Company, Minneapolis, Minn.—New cargo pumps; fuel oil service and transfer units demonstrated in operation, driven by well-known standard types of marine motors; illustrations of Northern rotary pumps on bilge, sanitary, fire-protection and fresh water duties in marine and shore service. Representative: J. A. Hense. Booth 55.

Pacific Mail Steamship Company.—Exhibit in conjunction with U. S. Shipping Board. Booth Oriental in decorations. Representative: J. P. Sutherland. Booth 266.

Pantasote Company, 11 Broadway, New York.—Vehisote standard panel board for all joiner work; Pantasote leather for seats, curtains and all upholstery; partial cabin showing construction of ceilings and bulkheads. Representative W. A. Lake. Booth 30.

Peabody Engineering Corporation, 110 East 42nd Street, New York.—Peabody-Fisher wide range mechanical burner; Peabody draft gage; standard burner and air register, so mounted as to show all connections and the method of attaching this register to the boiler front without the use of any special burner tile, using instead ordinary arch brick. Representatives: J. P. Leask, E. B. Sadtler, R. I. Condon, E. L. Delafield. Booth 15.

Penton Publishing Company, Cleveland, O.—*The Marine Review.* Representatives: A. O. Backert, R. V. Sawhill, W. S. Doxsey, F. V. Cole, Joseph Fuller, A. H. Jansson. Booth 32.

Pioneer Company, 25 Broad Street, New York.—Various types of metallic packing for steam engines in full size models. Representatives: G. Thiessen, G. W. Jenson, Mr. McDonough. Booth 273.

Pneumercator Company, 40 Flatbush Avenue, Brooklyn, N. Y.—Pneumercator tank gages, ship's draft gage, distant boiler gage glass (the latter, located in the engine room or chief's office will reproduce in full size the boiler gage glass enabling the officer on watch to know at all times the height of water in the boiler). Representatives: G. Cornett, H. S. Parks, W. Thomas. Booth 8.

Port of New York Publicity, 5 Beekman Street, New York. Representative: A. R. Arnheim. Booth 46.

Power Specialty Company, 11 Broadway, New York.—Foster superheater. Representatives: J. J. Nelis, John Kilfeather. Booth 106-B.

Roto Company, Hartford, Conn.—Tube cleaners for Scotch marine watertube and firetube boilers; condenser cleaning apparatus; plate and hand hole scrapers. Representatives: J. V. Doherty, W. R. Van Nortwick, W. M. Kelley. Booth 352.

Row & Davis Engineers, Inc., 90 West Street, New York.—Paracoil evaporator, feed water heater, oil heater, water still; RanD system for reliquefying bunker oil without steam coils in the double bottom tanks. Representatives: R. R. Row, H. C. Davis and Messrs. Thompson and W. Young. Booth 65.

Scovill Manufacturing Company, Waterbury, Conn.—Brass mill products and manufactured articles; seamless tubing, sheet metal, rods and wire made from brass, bronze and nickel silver besides a representative collection of manufactured articles; Scovill condenser tubing; numerous slides will illustrate how the Admiralty mixture condenser tubing is

made; exhibit of metallographic microscope and numerous specimens of metal; samples of corroded condenser tubing; Admiralty condenser tubing; booklet on tube manufacture. Representatives: Philip Davidson, E. L. Carter, C. A. Gleason, M. L. Sperry, Jr., L. L. Williams and E. H. Callanan. Booth 59.

Shipping, 82 Beaver Street, New York.—Representatives: John Collins, Peter Bain. Booth 358.

Sperry Gyroscope Company, Brooklyn, N. Y.—Gyro compass; helm angle indicator; ship stabilizer model; high intensity searchlight; "mechanical quartermaster" (simplified gyro compass). Representatives: R. B. Lea, Messrs. Whitaker, Conover, Jobson. Booths 22, 23 and 24.

The Stamford Foundry Company, 117-149 Canal Street, Stamford, Conn.—Shipmate ranges in various sizes; Oxo kerosene burner. Representative: F. W. Brant. Booth 327.

Sterling Cooper Corporation, 220 West 42nd Street, New York.—Sterling's Marine Catalog and other publications. Representatives: F. W. Sterling, T. G. Newbery, E. Zahn, G. P. Nightingale. Booth 71.

B. F. Sturtevant Company, Hyde Park, Boston, Mass.—Forced draft unit; 5 kilowatt gasolene engine generating set; steam turbine; electric driven ventilating sets; 75 horsepower gasolene propulsion engine. Representatives: E. B. Williams, E. L. Moran. Booth 111.

Submarine Signal Company, Boston 9, Mass.—Submarine pneumatic bell; Fessenden oscillator. Representatives: W. L. Gifford and E. P. Howe. Booth 326.

The Superheater Company, 17 East 42nd Street, New York.—Model of the Elesco fire-tube superheater as applied to the Scotch marine type of boiler; model of the Elesco superheater as applied to marine watertube boilers and boilers used on river boats; steam pyrometer for measuring steam temperatures; engineering data and literature. Representatives: H. B. Oatley, G. E. Ryder, C. A. Brandt, G. C. Fuller, W. H. Lovekin, G. E. Kershaw, W. McLintock, G. L. Moore, J. A. Barnes. Booth 66.

The Texas Company, 17 Battery Place, New York.—Lubricating oils and greases for every purpose aboard ship; fuel oils for bunkers and Diesel engines of all standard makes; literature on the use of oil-burning equipment will be distributed; other technical matter will deal with the lubrication of all primary and auxiliary units including reciprocating engines, turbines, Diesel engines, ice machines, dynamos and blower engines. Representatives: F. J. Shipman, D. Perry Quinn, J. L. Ward, L. O'Malley, E. A. Lobb, H. W. Schilling, R. A. Fischer and Al. St. James. Booth 16.

W. & J. Tiebout, 118 Chambers Street, New York.—Complete assortment of marine hardware and supplies. Representatives: John Tiebout, Sr., John Tiebout, Jr., G. V. Carlin, J. D. Gillespie, F. J. Morissey, C. H. Schult. Booth 29.

P. S. Thorsen & Company, Inc., 81 Coffee Street, Brooklyn, N. Y.—All types of insulation for steam and brine work and the best method of application. Representative: M. L. Bullard. Booth 107.

Todd Shipyards Corporation, 25 Broadway, New York.—Todd fuel oil burning systems for marine and stationary practice; Todd mechanical burner; steam atomizing burner; Todd "Guardian"; Todd thermofeed regulator; differential pump governor; Elesco firetube superheater and other steam saving specialties. Representatives: H. Nightingale, G. P. Haynes, R. Payne, R. Sterling, T. Torgensen, Jr. Booth 84.

Tuco Products Corporation, 30 Church Street, New York.—"Flexolith" composition flooring material shown in Pantasote Company's exhibit, Booth 30. Representatives: D. W. Pye, Walter Byrnes.

Underwood & Underwood, 6 East 39th Street, New York.—Photographic materials of all kinds. Representatives: F. Lacey, A. V. Jones, H. S. Redell. Booth 44.

United American Lines, 39 Broadway, New York.—Model 14 feet long built with unusual accuracy and detail of the S. S. *Reliance*. Representatives: H. Doblin, J. A. Lovett, J. Pannes, Charles Edwards, E. A. Winkler, James Dowd, Charles Faulkner, William Siemers, J. Jensen, W. Rehm, J. A. Pirnie, C. C. Wardlow. Booths 274 and 275.

United States Lines.—Exhibit in conjunction with the United States Shipping Board. Booth will be European in its decorations in accordance with the plan to have the Shipping Board operating companies represent in their decorations the services in which they run. Representative: E. E. McNary. Booth 258.

United States Navy, Washington, D. C.—Airplane propeller; Liberty motor; propeller for Martin-Bomber; dummy bomb, 1,000 pounds; Mark IV dummy bomb; Mark V dummy bomb; No. 230 Mark I dummy bomb; No. 520 Mark I dummy bomb; Mark III pilot directing bomb sight; 21-inch torpedo, Mark I, model 1; Mark III collapsible head for torpedo; 21-inch two-wheel torpedo truck; set of exhibition models, ⅛-inch scale, comprising the following vessels, showing the development of the vessels from the beginning of the Navy up to the present time: *Bon Homme Richard, Constitution, Enterprise, Ohio, Hartford, Monitor, Merrimac, Benton, Chicago, Brooklyn, Oregon, T. B. Winslow*, torpedo boat destroyer, dreadnaught, battle cruiser, scout cruiser, submarine, *N. C. 4*.

Exhibition models, Frigate *Vermont,* destroyer *Sampson,* submarine *S-3, Oklahoma, Connecticut, Pennsylvania.*

Range finder, Mark XI, with carriage and tripod; Mark VI mine outfit complete; telescope; stadimeter; Colt machine gun; Lewis machine gun; 3-inch dummy cartridges; 1 pounder dummy cartridge; 3 pounder dummy cartridge; 6 pounder dummy cartridge; 3"/23 dummy cartridge; 4"/50 dummy cartridge; 5" projectile, target; 6" projectile, target; 8" projectile, target; 12" projectile, target; 14" projectile, target; 16" projectile, target; 5"/51 charge, dummy; 6" charge, dummy; 8" charge, dummy; 12" charge, dummy; 14" charge, dummy; 16" charge, dummy; 5" to 14" powder tanks.

Three-inch anti aircraft gun; loud speaking radio transmitting and receiving set. Paintings showing heroic deeds of men in Navy and Marine Corps during the world war. Booths on second floor.

United States Shipping Board, Washington, D. C.—Reproduction of a suite of rooms from the "535" type of vessel; each of the four operating lines will have their own booths which will be suitably decorated according to the service in which they run. Representatives: E. E. MacNary, F. W. Wolf, J. P. Sutherland, T. J. Kehoe. Booth 250.

Valentine & Company, 456 Fourth Avenue, New York.—Valspar, Valspar varnish-stains, Valspar enamels. Representative: Dorning Walker. Booth 45.

Victor Engineering Company, Harrison Building, Philadelphia, Pa.—Victor marine ash ejector (without a pump) in full size, showing rearrangement of operating mechanism so that lower part is removed entirely into the bilge, leaving nothing visible above floor; charts of steam consumption and capacities of ejector. Representatives: E. Hahn, C. L. Bachman. Booth 12.

Wager Furnace Bridge Wall Company, 108 Academy Street, New York.—The Wager patent bridge wall for Scotch and watertube boilers for marine and stationary use. Representatives: A. Halley, L. F. Fenwick. Booth 98.

Wailes Dove-Hermiston Corporation, 17 Battery Place, New York.—Samples of Bitumastic and Hermastic solution and enamel; Bitumastic colored paints, as applied to steel plates. Representative: Linden Stuart. Booth 360.

Westinghouse Electric & Manufacturing Company, 165 Broadway, New York.—Complete model of Diesel electric propelling equipment; model of Kingsbury thrust bearing; 100 kilowatt turbine generator set; marine type 1,500 shaft horsepower reduction gear and pinion; flexible frame pinion; watertight deck winch motor and control; marine gasoline electric lighting set; one of the two types of air ejectors developed for marine use, Navy type circuit breakers, marine type bracket fans, and other examples of supply apparatus. Representatives: C. C. MacMillan, H. Peterson, H. L. McCarter, W. B. Bassett, H. W. Loren, R. D. Aldridge, C. M. Brown, R. M. Davis, L. E. Howell, N. R. Sibley, T. A. Fensenig, W. H. Easton. Booth 85.

C. H. Wheeler Manufacturing Company, Lehigh and Sedgley Avenues, Philadelphia, Pa.—Vacuum pumps and condensate pumps, also dynamometers for testing the horsepower of gas and Diesel engines, Radojet air pump. Representatives: C. Lang, J. Mullan and J. Dobson. Booth 7.

C. A. Woolsey Paint & Color Company, 500 Grand Street, Jersey City, N. J.—Display cards and descriptive matter showing "Adamant" deck paint, copper paint, yacht white, engine enamels, "Glisto" enamel, spar varnish, iron and steel bottom paint, steam compounds, etc. Representatives: P. Varley, Arthur Scott, E. D. Kelly, A. F. Hahn, F. T. Myer. Booth 13.

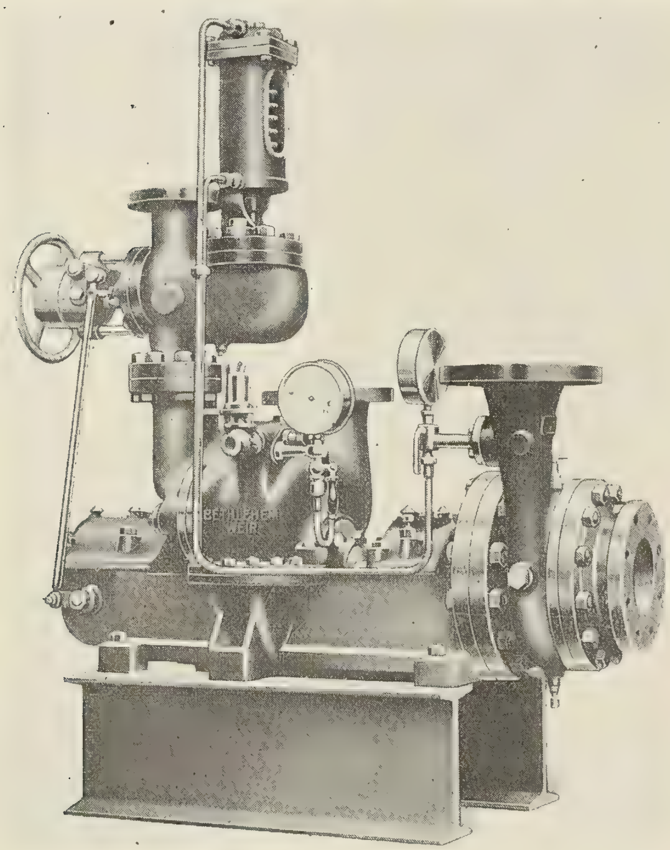
Worthington Pump and Machinery Corporation, 115 Broadway, New York.—Sixty horsepower 2 cycle solid injection Diesel oil engine of the type employed for auxiliary generator driving on board ship; small pumps and similar machinery; first direct acting steam pump ever built in the world. Representatives: W. A. Cather, M. L. Katzenstein, C. B. Humphrey, I. W. Jackman, H. L. Conklin, J. J. Morch. Booth 100.

New Devices to be Exhibited at the Marine Exposition

Turbine Driven Feed Pump

THE Bethlehem-Weir turbine drive feed pump will be shown at the Marine Exposition for the first public exposition demonstration. This pump, of the type shown in the accompanying illustration, will be a feature of the Bethlehem Shipbuilding Corporation, Ltd., exhibit.

The Bethlehem-Weir turbo feed pump consists of a steam turbine of the impulse type having one pressure and several



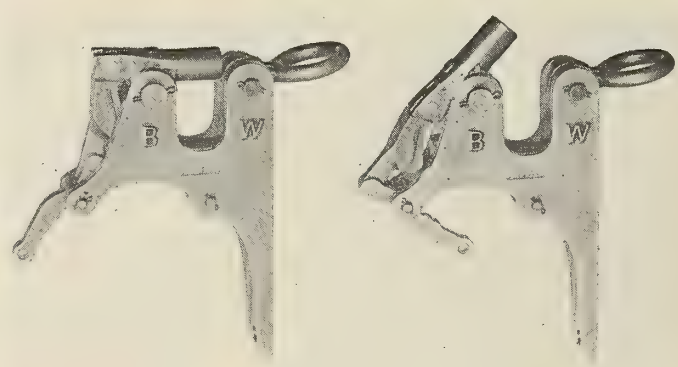
Compact Bethlehem-Weir Turbo Feed Pump

velocity stages working in conjunction with a single stage centrifugal pump of special design. The result is a compact unit which, it is claimed, gives perfect alinement, smooth and noiseless operation and is capable of pumping a steady flow of feed water against the highest boiler pressure. Variations of boiler steam pressure and pump discharge pressure are automatically controlled by a hydraulic governor. A safety governor shuts off the steam when the speed exceeds the maximum requirements for specific operating conditions.

Safety Lifeboat Releasing Device

IN order to provide an instantaneous, safe means for releasing lifeboat falls, either under normal conditions of service or when a ship is in a sinking condition, Dr. Charles Hunt, of Washington, D. C., has invented a detaching gear for lifeboats. A special feature of the device is that a lifeboat may be released while the ship is traveling at 15 knots' speed ahead and the lifeboat is dragging through the water with the full strain on the release gear. Release is also positive even with the boat dragging with her bow 60 degrees out of water.

At the present time several sets of the releasing device are



Lifeboat Releasing Device in Closed and Open Positions

being manufactured by the William Cramp and Sons' Ship and Engine Building Company, Philadelphia, Pa., for installation in lifeboats on several U. S. Coast Guard vessels. This company controls the rights for manufacturing and selling the gear.

The gear consists of only three working parts, weighs but 15 pounds and requires but 3½ hours to make a complete installation. The body may be either a bronze or a steel casting in which are fitted a toggle jointed trip for releasing the falls, a trigger which actuates the toggle, a pulley over which the trigger line is led to the release lever and a shackle to which the boat painter may be attached. A safety lock prevents accidental release and there are no projecting parts to cause danger when handling the boat.

From the illustration the releasing action of the device is quite evident. The release lever and drum controlled by one

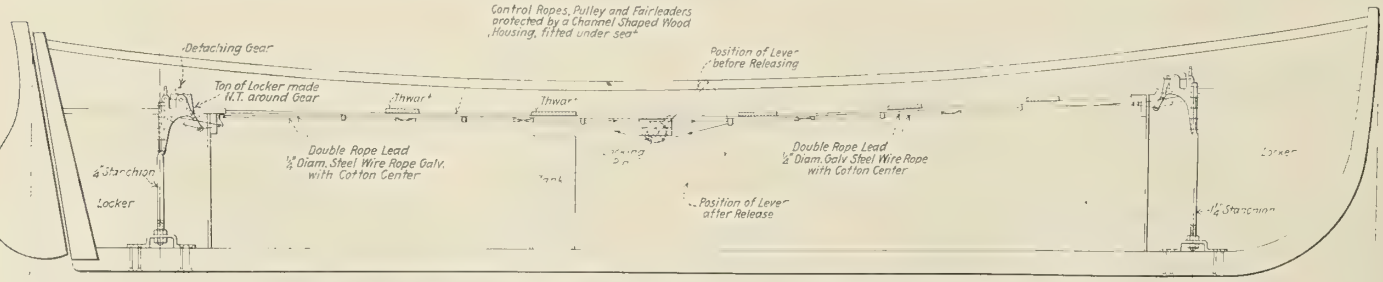


Diagram of Lifeboat Showing Hunt Releasing Equipment Installed

man are located along the thwarts of the lifeboat and trigger lines led through pulleys to the triggers of each device. The two gears are adjusted to release simultaneously and will so function under practically any condition of stress to which the ship may be subjected.

A demonstration of the detaching gears installed on lifeboats of the S. S. *General Rucker* in May, 1922, was entirely successful and called forth recommendations from those who witnessed the demonstration. As soon as the sets of gears now under construction have been installed on boats of the Coast Guard, tests will be made by the U. S. Steamboat Inspection Service for their official approval.

Mechanical Device for Steering Ships

THE Sperry Gyroscope Company, Brooklyn, N. Y., has developed a device known as the "mechanical quartermaster," which will successfully steer ships by mechanical means alone. It is claimed that the equipment has steered vessels on 4,000 mile voyages, making all courses and land falls desired.

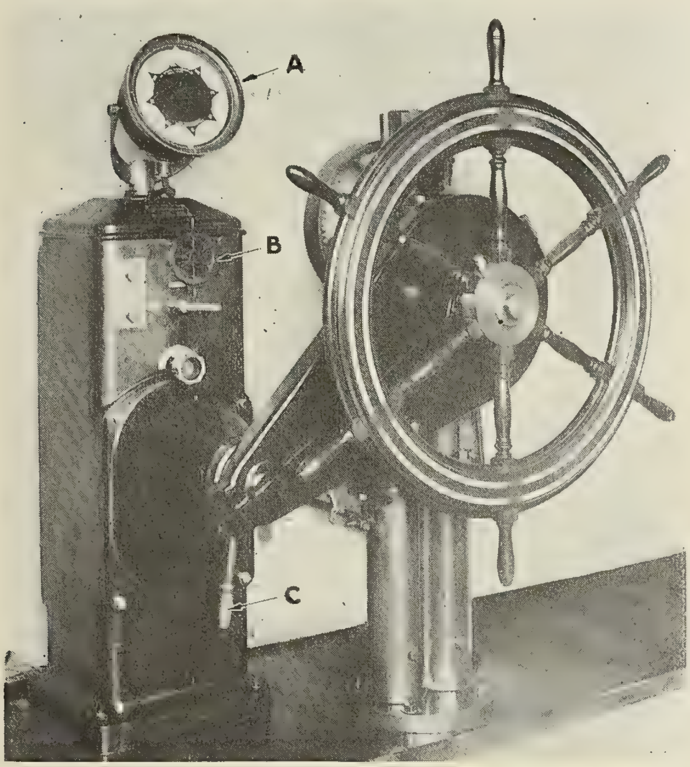

Fig. 1.—Installation of the "Mechanical Quartermaster"

The following extract from a report made by a ship's captain to the owners indicates the success of the device: "Steered all the various courses around the Florida reefs and across the Gulf of Mexico without any variation in course. Steered a straighter course than any wheelsman could steer." This latter statement is corroborated by the sample course chart shown in Fig. 2, which indicates that while the vessel was controlled by hand the course varied to a greater extent than when under the control of the "mechanical quartermaster."

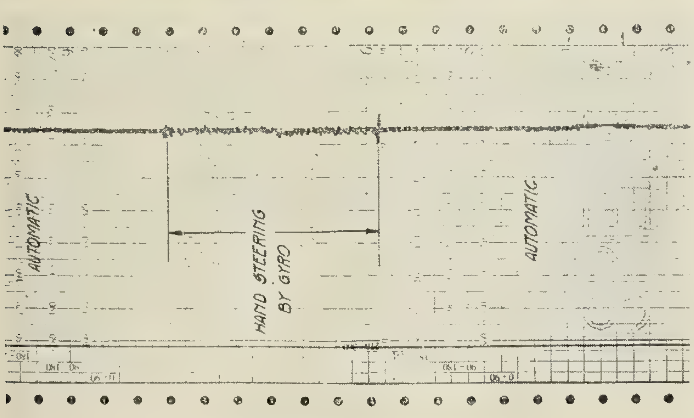

Fig. 2.—Sample Course Chart

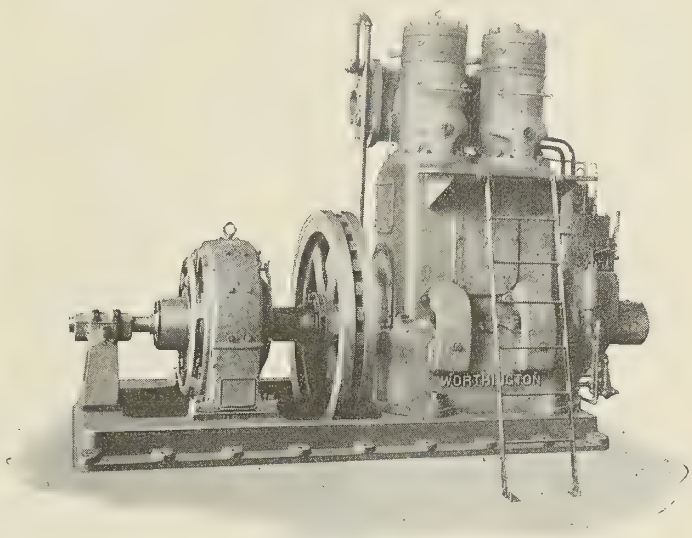
The device has only been brought to perfection in recent months but it is the result of many years' development, work on it being halted during the late war.

The illustration of the device is shown herewith. *A* denotes the repeater compass, *B* the wheel controlling the mechanism for hand setting the desired course and *C* the clutch for disconnecting the "mechanical quartermaster" when it is desired to steer the ship by hand.

Two-Cycle Diesel Driven Generator Set

A DIESEL engine driven generator set of high efficiency for marine auxiliary current supply and emergency service has recently been developed by the Worthington Pump and Machinery Corporation, New York. The unit consists of the vertical two cylinder, two cycle type,



60-Horsepower Worthington Diesel Generator Set

solid fuel injection Worthington Diesel engine direct connected to a General Electric direct current generator. Each of the engine power cylinders has a bore of 10¼ inches and a stroke of 10½ inches. The engine develops 60 horsepower running at 375 revolutions per minute; the General Electric generator used has a rating of 40 kilowatts.

The illustration shows a complete unit which is similar to two recently ordered for the S. S. *Leviathan*. These sets are to be used for emergency service in case of accident to the main steam plant as well as for auxiliary current supply.

Insulating Quality of 85 Percent Magnesia Increased by New Process

IN the process of manufacturing 85 percent magnesia pipe and boiler coverings, the Keasbey and Mattison Company, Ambler, Pa., now uses carded asbestos fibers as the binding element. Before this time 85 percent magnesia has consisted of from 75 percent to 85 percent basic magnesium carbonate and from 15 percent to 25 percent of a relatively

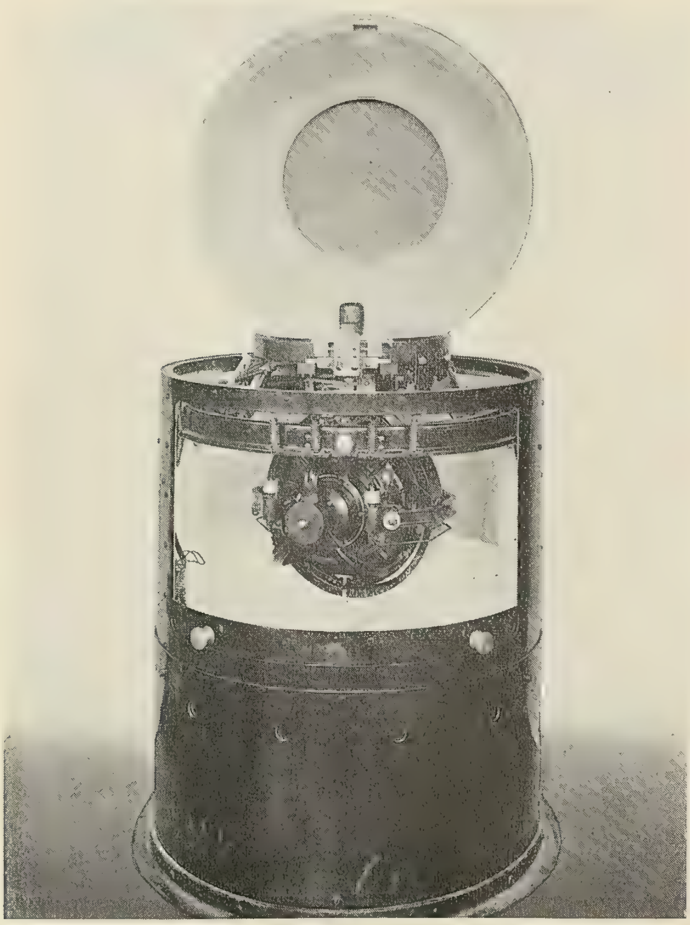
short fibered asbestos which was simply crushed and not carded.

By using the longer fiber asbestos and carding it, the required structural strength for the covering is now obtained by using 10 percent and even less asbestos. The use of the smaller percentage of asbestos permits a minimum of 90 percent basic magnesium carbonate and, since the value of insulating material is due to the cellular construction of the magnesia, which is made up of the most minute dead air cells, the resulting product insures a high insulating efficiency. The asbestos fiber itself gives little or no assistance in so far as the heat insulation is concerned, merely acting as a reinforcing constituent and binder to give the material necessary rigidity and structural strength. The manufacturers claim that increased insulating efficiencies as high as 10 percent have been demonstrated in recent tests on covering made up with the carded asbestos.

New Gyro Compass Adapted from Navy Type

THE Mark VI gyro compass, built by the Sperry Gyroscope Company, Brooklyn, N. Y., embodies new and improved features as a result of ten years' service and experience coupled with extensive research and development work. This compass is designed after the Sperry Navy Mark V compass stripped of refinements required by the Navy for gun fire control accuracy.

The design follows the single wheel mercury ballistic type. The rotor of this compass is made of bronze, runs at the conservative speed of 6,000 revolutions per minute, weighs 59 pounds and is driven by a direct current motor operating on a current of 70 volts. The system of suspension is of exactly the same general type, although slightly modified as that in previous types of single gyro compasses. A notable feature of the compass is the fact that the card is the highest part of the compass and has no obstructions over it, giving full 360-degree visual access to the card.



Mark VI Sperry Gyro Compass

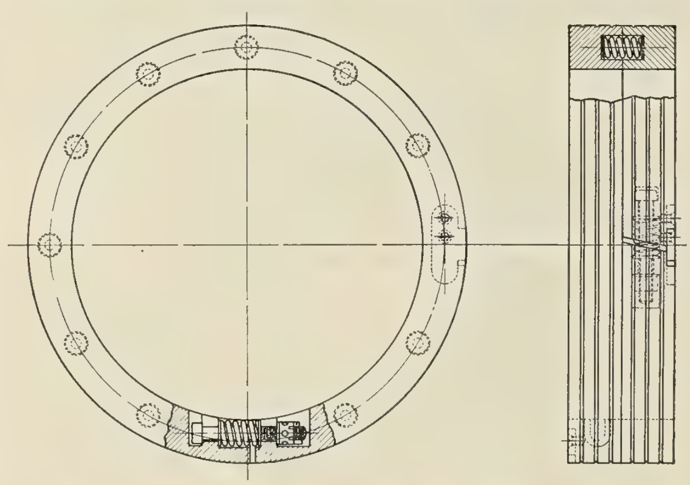
The transmitter is of the commutator type and carries a lost motion device which is designed to eliminate the hunting motion of the repeaters without introducing any actual lost motion. The azimuth motor is about the size of a 1/8-horsepower fan motor, its armature being connected to the azimuth gear through one idler gear only which simplifies this part of the equipment.

The regular source of current supply for this equipment is obtained from a small half-kilowatt steam turbo generator taking steam up to 140 pounds pressure using a reducing valve and generating current at 70 volts. In addition, the compass is wired so that it can be operated from the ship's current supply through resistance.

This compass will be a feature of the Sperry exhibit at the Marine Exposition.

Piston Rings Developed for High Pressure and Superheat Service

AFTER a thorough investigation of requirements for piston rings to withstand high pressures and high degrees of superheat for marine work, the Hooven-Owens-Rentschler Company, Hamilton, Ohio, has developed the Hamilton-Damara type piston ring which can be applied to marine reciprocating engine service.



Hamilton Damara Piston Ring, Showing Bolt for Adjustment.

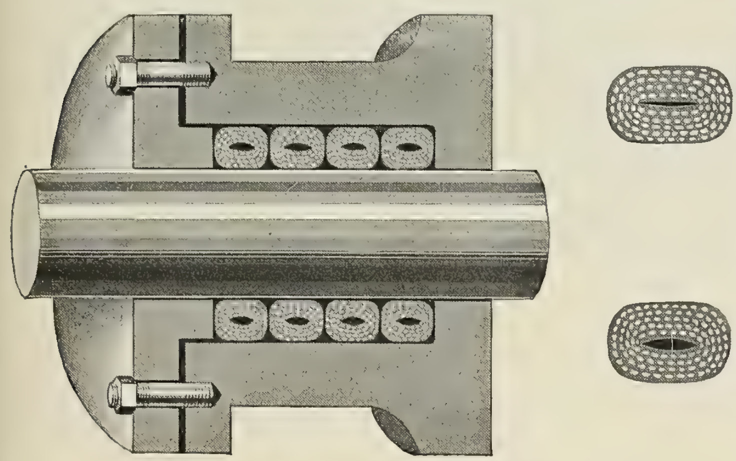
These rings are cast from single patterns made especially for each size ring. In the casting, care is taken to eliminate hardness, to check and control the precipitation of graphite, which process insures homogeneous ring castings and to insure uniform resiliency around the entire ring circumference.

It is stated that the Hamilton-Damara piston ring is virtually an adjustable plug piston, the adjustment being readily made by means of a machine steel bolt to which a special castellated case-hardened fine thread steel nut is fitted. In order that the required amount of tension may be obtained, a steel coil spring of special manufacture to withstand high temperatures under continuous tension is fitted to the ring in connection with this bolt and nut. To seal the top and bottom of the two rings which form the piston ring packing, a number of special steel coil springs are set in pockets between the two rings. These are clearly shown in the accompanying illustration.

Split Core Packing Introduced in the Marine Field

VARIOUS type packings based on the air cushion principle developed by Mustor Manufacturing Company, Inc., New York, have recently been introduced in marine service.

The oval split core packing made in spiral ring or coil form in sizes ⅜-inch up by 16th's is adapted to stuffing box service under steam pressures as high as 150 pounds where the box is deep enough to take at least 3 rings. This packing is built of cotton duck properly frictioned together around a rubber core with rubber friction compound. The special feature is the split core which is made of soft, tough, slow ageing rubber with a split running longitudinally through its center. The accompanying illustration shows how with increasing gland pressure the expansion of the packing increases, automatically opening up an air cushion.



Oval Type Split Core Packing

The cross diagonal split core packing combines the split core air cushion principle of the oval type with the well known cross diagonal packing construction. It is recommended by the company for outside and inside packed pumps, cylinder elevators and cold and hot water piston rods.

A third type packing, known as the flat ring type, for outside packed plunger pumps and plunger elevators was designed to effect an absolute seal by means of a resilient flap.

Boiler Water Level Reproduced by Gage Glass at Distant Points

AN instrument named the "Pneumercator Distant Gage Glass" has been perfected by the Pneumercator Company, Inc., Brooklyn, N. Y., to reproduce the gage glass on the boiler at full size and filled with water at distant points in a vessel. The instrument itself can be located either above or below the boiler and at any distance from it, such as the engine room, central control station or the chief engineer's office. This is of importance on oil burning vessels where in many cases each separate fire room is shut off from direct connection with the engine room, the entrance being made from the deck above. This necessitates the engineer on watch to travel from one fire room to another to read his gage glasses. By the use of the distant glass, the gage glasses for all boilers can be located at any convenient spot.

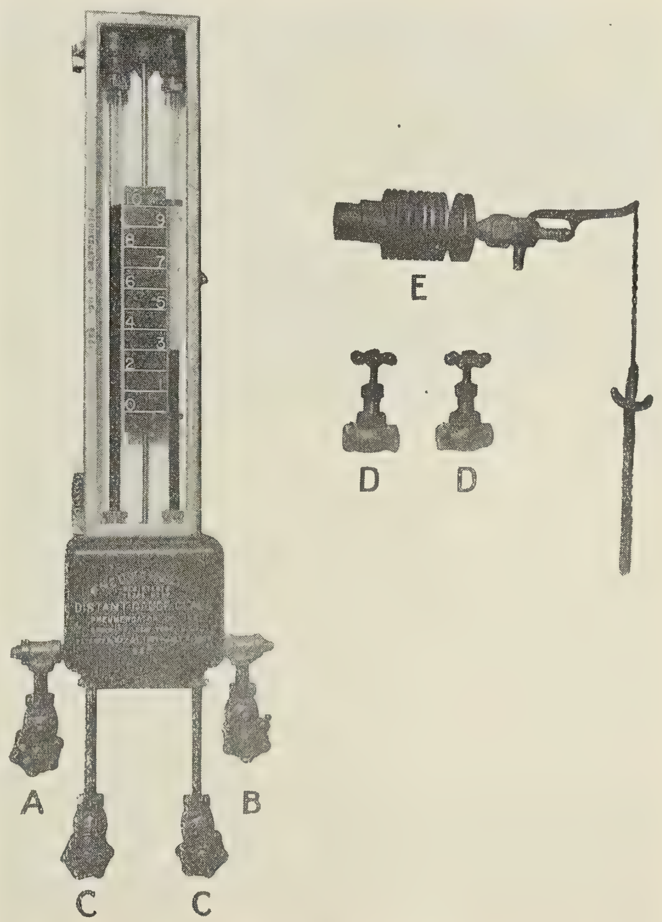
The indicating portion of the instrument itself as shown in the accompanying illustration is in its lowest terms an inverted "U" tube, each leg of which is directly connected to the boiler by ⅜-inch brass pipe; one leg which is known as the steam leg is connected to the steam space of the boiler at the top of the boiler gage glass and the other, or water leg, to the water space of the boiler below the gage glass. Both legs are cross connected by a special fitting which is called a maximum tube and which in reality is a small condenser. The center of the maximum tube is located on the same elevation as the top of the gage glass on the boiler.

When the valves connected to the boiler and the indicating portion of the instrument are open, the water leg line will fill with water directly from the boiler and the steam leg line will fill by condensation to the point where the water in the steam leg flows through the cross connection (maximum tube) back to the water leg and then to the boiler.

When these lines are both filled with water the following condition exists: The steam leg near the boiler is filled to the center of the cross connection (maximum tube) and the water leg to the level of the water in the boiler, or to the same level as the gage glass on the boiler indicates.

Now as both the water lines are subjected to the boiler steam pressure, the water is forced through the pipes to the instrument which is arranged to read the differential between the fixed head of water in the steam leg and the varying head in the water leg. The water level in the steam leg of the instrument itself always represents the bottom of the top gland nut on the boiler gage glass and when the top graduation of the sliding scale between the two columns of the instrument is placed opposite this level the actual water level in the boiler is shown in the right column of the instrument.

The tubes used in the instrument itself are standard for any size boiler and any pressure from 25 to 300 pounds. The sliding scale is laid out to correspond with the gage glass on the boiler. For instance, the illustration shows an instrument designed for a 10-inch gage.



Operating Parts Supplied with "Distant Gage Glass" Equipment. A, Steam Leg Valve; B, Water Leg Valve; C-C, Water Drain Valves; D-D, Valves; E, Maximum Tube

New Canadian Pacific Liner Montclare, of 16,400 Tons

Atlantic Liner Montclare Increases Canadian Service

The Latest Addition to Canadian Pacific Fleet Completes Construction Program for Passenger Vessels

THE passenger vessel *Montclare,* a sister ship to the *Montrose* and *Montcalm,* of the Canadian Pacific Steamships, Ltd., recently completed her maiden voyage from Liverpool to Canada. With her completion, the passenger ship program of the company is finished, the other vessels having been commissioned in the Atlantic service early in the year. The *Montclare* was built by Messrs. John Brown & Company of Clydebank, Scotland. It is interesting to note that the company has added a fleet aggregating 134,607 gross tons to its service in a single year.

General Details of the Montclare

The *Montclare,* like her sister ships, is built to Lloyd's highest classification and meets all the requirements of the Board of Trade as a passenger ship. The principal dimensions of the vessel are:

Length between perpendiculars	549.5	feet
Length on the waterline	563	feet
Breadth, molded	70.2	feet
Depth to shelter deck (C deck)	43.25	feet
Depth to boat deck	68	feet
Gross tonnage	16,400	

The vessel is of the shelter deck type with the bridge deck extending almost the full length with long erections above. Twelve watertight bulkheads, extending to the shelter deck, divide the ship into thirteen watertight compartments. A cellular double bottom, in which is stored oil fuel, reserve feed water, fresh water and water ballast, extends fore and aft the complete length of the ship and is carried well up to the bilges, giving additional protection in case of collision or accident at sea. The machinery spaces are further shielded by longitudinal bulkheads. Fresh water tanks are also built alongside the shaft tunnels.

Accommodations

Provision is made for 554 cabin passengers in staterooms amidships which are arranged for 2 and 4 passengers each. The cabin dining saloon, which extends for the full breadth of the ship, is situated on "D" deck amidships convenient to the main entrance.

At the forward end of "A" deck is the cabin lounge arranged in small bays and corners with a separate writing room and a card room at the forward end. The lounge is decorated in Georgian style, giving a very pleasing effect. Forward of the cabin lounge is the card room on the port side paneled in French walnut while the writing room is located on the starboard side. Both rooms are well lighted by large windows and have electric fires.

Abaft of the after funnel hatch on the same deck the cabin drawing room is situated with a raised deck over and a large bay window on one side. Next to this is located a children's room.

The cabin smoking room is arranged at the aft end of "A" deck. The decorative work and furnishings have been carried out with care. This apartment is fitted with a large electric fireplace which adds to its comfortable appearance. Extensive promenading space for cabin passengers is provided on "A" and "B" decks.

Third Class Accommodations

Comfortable third class accommodations are provided on "D" and "E" decks in two, four and six-berth rooms. There is also available portable accommodation for an additional number of passengers. The total number of third class passengers carried is 1,252.

The third class dining saloon is situated on "A" deck aft. Two smoking rooms and two lounges are arranged for the comfort of the passengers, one of each is situated on "B" deck aft with smaller ones on "C" deck forward.

The captain's quarters are located on the navigating bridge, the officers on "A" deck forward and the engineers on "C" deck aft complete with cabins, bath rooms, lavatories and the like. The seamen and the boiler attendants and stewards are berthed amidships on "C," "D" and "E" decks.

The galleys, pantries and bakery for first and third class dining saloons are situated amidships on "D" deck. All the latest improvements for cooking and heating have been supplied.

The heating and cooling on the ship is by means of the thermotank system which insures a temperature of at least

Drawing Room

Nursery

65 degrees F. in the coldest conditions. Ten thermotanks are fitted sufficient to change the air in any one of the compartments to which they are connected at least eight times per hour.

Cargo Handling Equipment

Cargo is handled by means of steel tubular derricks fitted on the masts and derrick posts worked by means of fourteen electric winches. Each hatch is supplied with three derricks.

The watertight doors are operated by Brunton Bros. hydraulic gear and can be opened or shut either individually or collectively from the navigating bridge.

One of the special features of the *Montclare* and the *Montrose* is that the cabins have been fitted with Henderson-Robinson patent unjammable door and lock. The edges of this type door have been cut at an angle which renders it unjammable in case of a collision or other accident that would ordinarily distort the frame, jam the door and imprison the passengers. The locks on the doors are also unjammable.

First Class Dining Saloon

Ample lifeboat accommodations, according to the standards of the International Convention, are provided for all passengers and crew. Two rows of nested boats are fitted on sliding chocks so that they can be moved from one side of the ship to the other and are placed in Babcock and Wilcox (Wylie) patent double acting davits. The remaining lifeboats are worked by "Australis" patent davits. The vessel is also fitted with wireless telegraphy, submarine signalling and gyro compass. A complete fire extinguishing service has been arranged. Pneumercator tank gages are fitted in all oil fuel and fresh water tanks with indicators in the machinery space, so that the tanks are always under the supervision of the engineers.

Propelling Machinery of the Montclare

The propelling machinery is fitted in one engine room and consists of two sets of steam turbines of the Brown-Curtis marine type arranged to work with superheated steam in driving twin screws through double reduction helical gearing. Each set of turbines consists of one high pressure and one intermediate pressure turbine in tandem driving through one set of gearing and one low pressure turbine driving through the second section of the gears. Astern turbines are incorporated in the casings of the intermediate and the low pressure ahead turbines. Adjustable thrust blocks of the Michell type are fitted to the turbines and the bearings of the turbines and gearings are arranged to work under forced lubrication. One condenser of the underhung type is fitted to each set of turbines and bolted direct to the exhaust branch of the low pressure turbine.

The main shafting is of ingot steel and each line has a Michell main thrust block fitted next to the gearing. Propellers are of the built-up type with four manganese bronze blades; the bosses are of cast steel and cast iron cones are fitted over the propeller nuts.

The auxiliary machinery includes two centrifugal circulating pumps; two Weir "Dual" air pumps; two pairs of Weir feed pumps; two hot well pumps; one Weir surface and one direct contact feed water heater; two feed water filters of the gravitation type and necessary equipment for forced lubrication as well as sanitary fresh water and other service pumps. Complete evaporating and distilling plants, auxiliary condenser and pumps are provided.

Steam is generated by ten single ended cylindrical boilers arranged for burning oil fuel under the Todd mechanical system and for a working pressure of 215 pounds per square inch. These boilers are fitted with smoke tube superheaters. Each boiler has three furnaces and Howden's type of forced draft is used. The boilers are placed in two compartments and each boiler is equipped with a working and standby oil fuel installation complete with the necessary pumps, heaters and strainers. The forced draft fans are electrically driven there being two fans and motors to each of the boiler rooms.

The refrigerator spaces in the vessel, comprising a fish and ice room, meat and poultry room, fruit and vegetable room and milk and butter room, as well as Nos. 5, 6, 7 and 8 cargo holds, are insulated on the "J.D." patent unit system of insulation, consisting of a Deltah compressed cork slab and finished with a white composite insulating slab. The refrigerating machinery and ice machines are of the latest type.

Last of Five New P. & O. Steamers Completed

Twin Screw Passenger Vessels of 15,100 Tons Built by Harland and Wolff for Emigrant Trade to Australia

With the completion of the S. S. *Bendigo,* a twin-screw passenger vessel of 15,100 tons, Harland and Wolff, Ltd., Greenock, has delivered to the Peninsular and Oriental Steam Navigation Company for its branch line service from London to Australia, via the Cape, five sister ships especially designed for the emigrant trade. The new vessel, which is classed 100 A.1 at Lloyd's, is 520 feet by 64 feet by 41 feet. Accommodation on a very complete scale has been provided for about 500 cabin passengers and accommodation is available for nearly 1,000 third class passengers on the main deck. Nine bulkheads divide the vessel into ten watertight compartments, and the double bottom is sub-divided for water ballast or fresh water, the fore and aft peaks being reserved for water ballast.

The main entrances are of a spacious and airy character. The dining saloon is a large apartment and is arranged to allow full complement of cabin passengers to dine at the same time. The framing is of a simple but pleasing character, having a teak and pitch pine dado with panelling above painted white. Every care has been taken to secure good ventilation and steam heating has been arranged all around the sides and ends of the saloon.

The music room walls are tastefully panelled and finished white with hardwood dado. This apartment is situated on the shade deck. The smoking room, which is on the boat deck aft, is panelled and painted in white with hardwood dado.

The staterooms are situated in the deckhouse on the shade

P. and O. Steamer Baradine, Sister Ship of the S. S. Bendigo

deck and also on the upper deck, and are arranged on the well known tandem principle, which ensures natural light and ventilation.

Electrical Equipment

The electrical installation consists of four main generators and one vertical oil engine driving a dynamo situated well above the waterline. All the watertight doors, which are electrically operated, can be closed simultaneously from the bridge. The ship's whistle is automatically operated electrically from the bridge.

The electrically driven gear includes large forced draft fans for the boilers, also refrigerating fans and large ventilation fans. There are two hoists for the pantry, and the dough mixer, dish washer and potato peeler are also electrically driven. Loud speaking telephones have been installed to assist in navigation, and there are considerably over 1,000 lights and above 70 motors in the vessel.

Propelling Machinery

The *Bendigo* is propelled by twin screws, driven by two sets of quadruple expansion engines, balanced on the Yarrow, Schlick and Tweedy system, thereby eliminating vibration as far as possible. The condensers are of the largest design, independent air and circulating pumps being provided. Steam is generated in 5 large coal burning cylindrical boilers working under forced draft. The engine room auxiliaries are all independent of the main engines and are of the latest and most up-to-date type.

High Speed Wire Brush for Cleaning Metal Surfaces

THE increasing use of air-driven wire brushes for cleaning metal surfaces has demonstrated the need of high rotative speed. Especially has this been true on such cleaning work as the removing of paint, rust, dirt and scale from tanks, steel ships, structural steel forms, etc., where the area to be cleaned is large and a fast rate of work is required. It has been found that a wire brush turning at high speed cleans faster and also stands up to the severe service much better than if only revolving at 2,000 or 3,000 revolutions per minute.

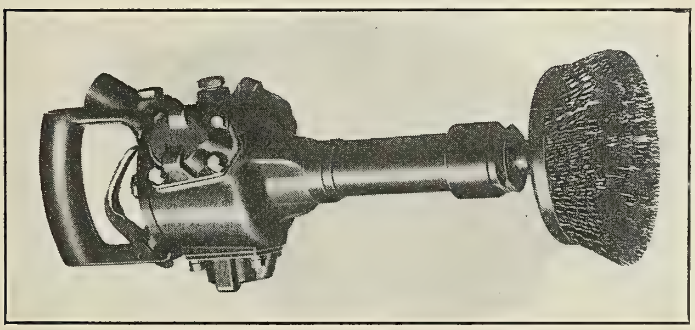


Fig. 1.—No. 601 Little David Wire Brush

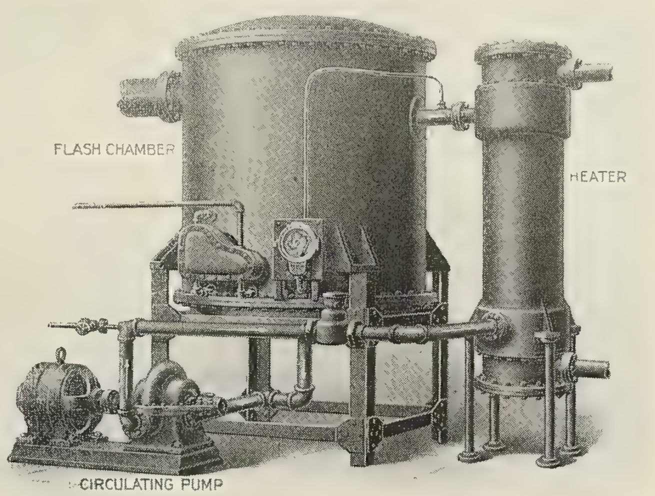
The Ingersoll-Rand Company, New York, has recently brought out a high speed cleaner (Fig. 1) known as the No. 601 Little David wire brush, which has a maximum speed of 4,200 revolutions per minute. This machine is said to be unusually successful in operation, effectively cleaning surfaces such as mentioned above and also iron and steel castings. It is designed to do a first-class cleaning job and effect a considerable saving of time and labor as well.

The air motor is of the three-cylinder type such as used in the Little David portable grinder which has been thoroughly tested out in the severe service to which pneumatic grinders are subjected. The machine is designed to be simple in construction, well balanced and operate without vibration. Light weight has been attained by using an aluminum casing reinforced with cast-in steel bushings. The weight of the complete machine is 14 pounds; the average free speed at 90 pound air pressure, 4,200 revolutions per minute; the length overall, 17½ inches and the diameter of the wire brush, 6 inches.

Non-Scaling Flash Evaporator for Producing Pure Feed Water

A FLASH evaporator having non-scaling features has been developed by the Schutte and Koerting Company, Philadelphia, Pa., for the production of pure boiler feed water. The equipment consists essentially of a tubular heater, an evaporator proper or flash chamber maintained under vacuum and a circulating pump. A distilling condenser is also used, if the vapor does not pass directly from the flash chamber to the main condenser—otherwise no distiller is required.

The raw water is heated in the tubular heater to a temperature that is both below the boiling point at atmospheric pressure and also below the temperature at which the impurities in the water are deposited as scale. This temperature is, however, higher than the temperature corresponding to the vacuum maintained in the evaporator. The circulating pump maintains the water in the heater under pressure and, as this heated water enters the evaporator, it flashes into vapor due to the vacuum existing therein.



Complete Flash Evaporator Unit

The flash evaporator is adapted for small, as well as large installations. Practically pure water is produced. It is claimed that even when salt water is used as evaporator feed the salt content of the distillate is less than 6 parts of salt in 100,000 parts of water.

The formation of scale in the heater and the precipitation and accumulation of other solid impurities are eliminated, the scale-forming impurities and other salts remaining in solution during the entire evaporation process, because of the low temperature at which evaporation takes place. This is also due to the fact that no evaporation can occur on the heating surface of the water heater. The system can be operated continuously.

The internal structure of the flash chamber is so arranged as to divide the incoming water into a multitude of thin films. This splitting of the water into slices or films is one of the outstanding characteristics of the flash evaporator and is one of the features wherein this type of evaporator differs from apparatus in which the raw water is ordinarily boiled in a large mass.

Diesel Engine Revolutions and Propeller Efficiency

Propeller Calculations for Single and Twin Screw Installations with Variable Revolutions and Fixed Speed of Ship and Also with Fixed Revolutions and Variable Speed of Ship

By A. J. C. Robertson*

ENGINEERS and shipbuilders are generally aware that low propeller revolutions are necessary to securing high propeller efficiencies, but how low these revolutions should be and what gain in efficiency can be obtained by dropping the revolutions are facts which it is very difficult to determine.

When the revolutions of the propeller are approximately the same as those of which experience has already been obtained in steamships, it is comparatively easy to forecast what the propulsive efficiency of the ship will be but, owing to the enormous weight of a slow speed Diesel engine, it has been the general practice of Diesel engineers to design their engines for higher revolutions per minute than is the case with reciprocating steam engines at present used in steamships.

It, therefore, becomes necessary, if any investigation is made of propeller efficiencies, to rely upon the data secured by model test experiments and published by Taylor, Froude, Durand, Luke, Rota and others.

*Naval architect, Munson Steamship Line, New York.

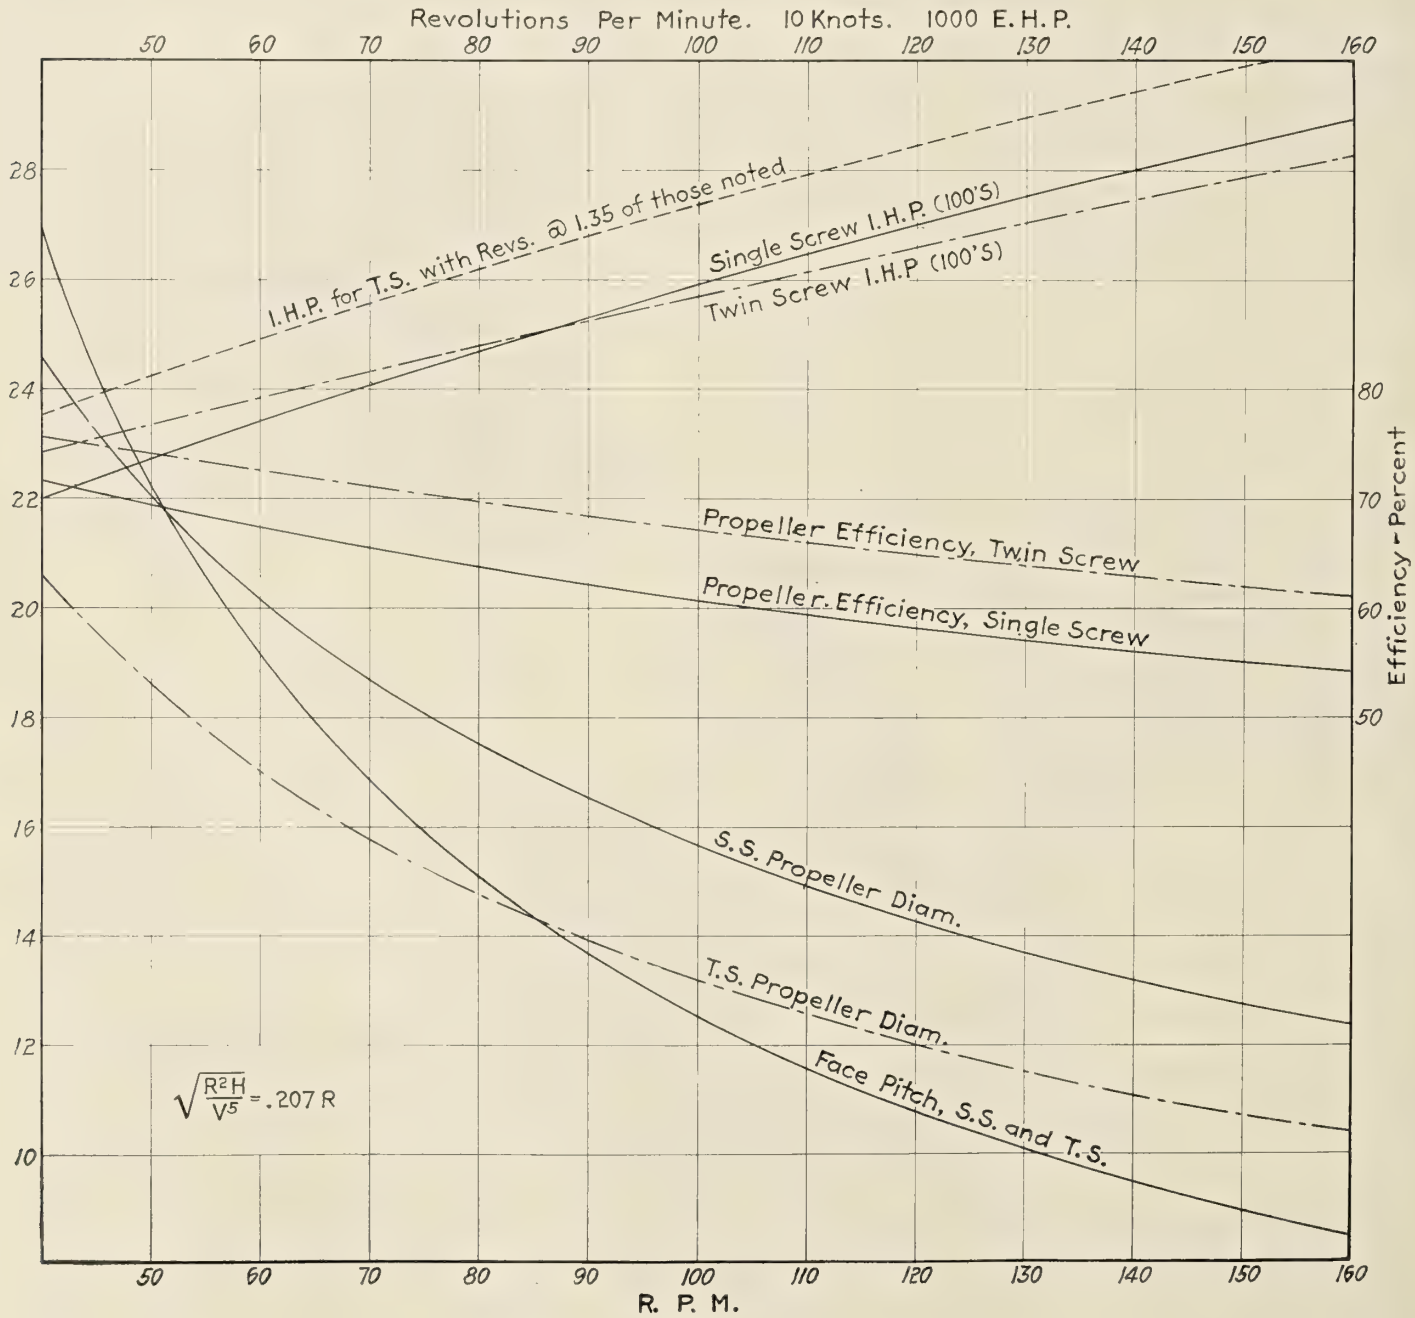


Fig. 1

Unfortunately the above data have been presented to the public in a large number of different forms, which render it inaccessible to those who have not the time to make an exhaustive study of the matter. Admiral Taylor has, however, presented a large number of his experiments in a form which is comparatively easy to apply to ship calculations, but even here the diagrams seldom extend to as high revolutions as are necessary to form a proper opinion on the subject.

R. E. Froude's classical paper on propellers presented to the British Institution of Naval Architects in 1908 is not so well known on this side of the Atlantic, but in some ways is even more useful for analysis purposes and can be plotted in the same way as Admiral Taylor's data. In the following notes the writer has made large use of Froude's as well as Taylor's model tests.

To illustrate the influence of revolutions upon propeller efficiency, the writer has assumed that it is desired to drive a ship of ten to twelve thousand tons deadweight at ten knots, and to do this it is assumed that one thousand effective horsepower is indicated by the model tests.

Estimate of Wake

When calculating the diameter and pitch of a propeller to absorb 1,000 horsepower at ten knots, the first thing necessary is to know what wake to anticipate in order to arrive at the speed at which the propeller advances in still water. This wake depends to a certain extent upon the diameter and location of the propeller, and to a very material extent on the fullness of the after lines of the vessel, such fullness being measured by the block coefficient, or more accurately by the prismatic coefficient of the after body.

I have been guided by Luke's experiments in assuming a wake fraction of 0.253 for this vessel with single screw and 0.190 for twin screw, these figures being the fraction of the speed of the ship. This gives us a speed of advance for the propeller of 7.47 knots for the single screw vessel and 8.10 knots for the twin screw vessel.

In addition we must remember that 1,000 shaft horsepower is the power required in a ship without propeller bossing, and for the twin screw vessel an allowance of 10 percent has been added to cover the resistance of the propeller bossings. It may be noted that this figure varies somewhat with the form of bossing on the ship, and to a certain extent with the amount of bossing, which is a function of the prismatic coefficient of the after lines, but 10 percent is a fair allowance to cover average practice for propeller bossings or struts.

A ship hull efficiency of unity has also been assumed.

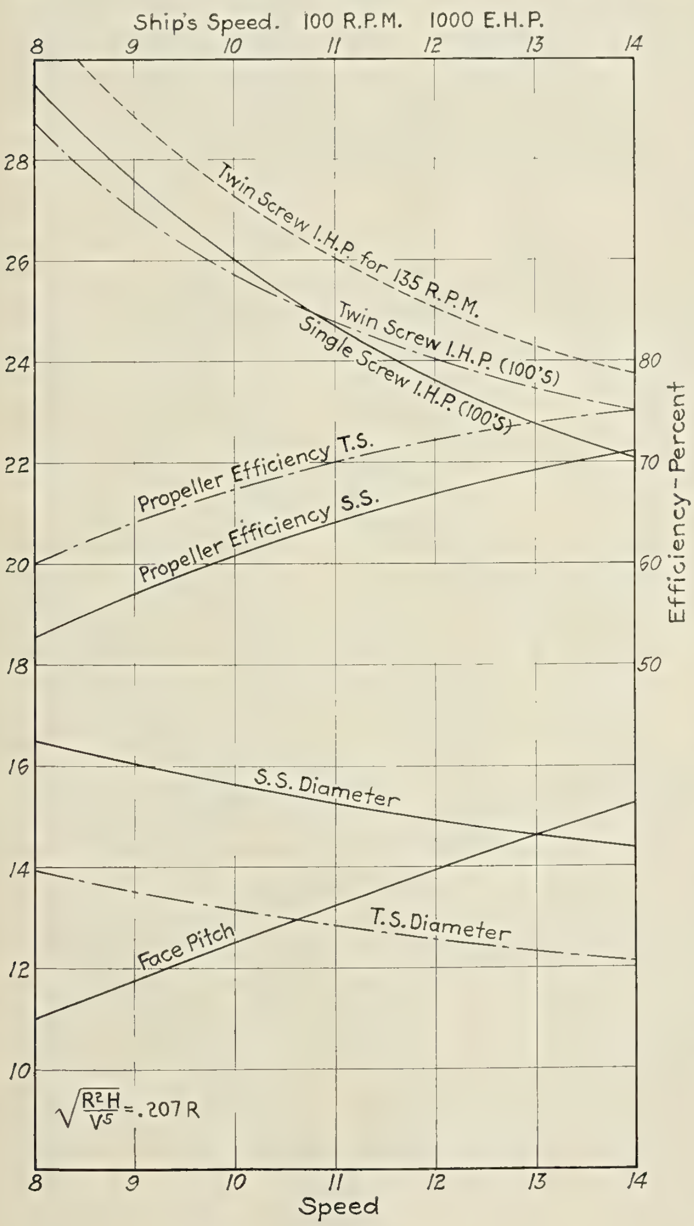

Fig. 2

Propeller Calculations for Variable Revolutions and Fixed Speed of Ship

For the above conditions propellers have been calculated with revolutions per minute of from 40 to 160, both for single and twin screw vessels, and the propeller diameters and pitches have been plotted on the diagram shown in Fig. 1.

This calculation assumes that three- or four-blade propellers of a mean breadth ratio of about 0.30, or a disk area ratio of 0.45, would be used; the blade thrust coefficient is taken as 92½ percent of Froude's coefficient for model propellers, in line with the full size thrust experiments of Holt. From these assumptions a calculation has been made of the slip ratio showing highest efficiency for the chosen revolutions and the pitch ratio and efficiencies thereby obtained. The diagrams therefore give propeller diameter, pitch and efficiency where the efficiency is highest, and it is interesting to note that the curves of pitch for the single screw and twin screw propellers are identical, though the condition of working as to load per square inch of propeller area is naturally very different.

On this diagram I have also plotted the propeller efficiencies as taken from Taylor's experiments and the corresponding indicated horsepower of the Diesel engines, assuming a rotative efficiency of 85 percent and a mechanical efficiency of 75 percent. This figure is possibly a little bit high, though higher figures are claimed for certain engines under certain conditions.

Power of Single and Twin Screws Equal at 88 Revolutions per Minute

From this diagram it will be noticed that at 88 revolutions the engine power is equal for single and twin screws, and that thereafter the twin screw engine shows a higher efficiency than the single screw installation. At 102 revolutions the power required on a single screw would be 2,600 indicated horsepower but, if put into twin screws, the revolutions would probably be, say, 130 and at that figure these engines would require to be of 1,350 horsepower each. Other comparisons are easily made from the diagram.

It will also be noted that as between 80 and 120 revolutions per minute, the excess power is 237 indicated horsepower, which would represent an additional fuel consumption per annum of approximately 150 tons. From such data it is possible to figure out whether the additional weight of the 80 revolution engine is worth accepting, or whether the addi-

tional deadweight capacity with the higher speed engine would not more than pay for the higher fuel consumption.

It is very interesting to note that the difference in diameter of the single screw and twin screw propeller is only 15 percent.

As against the higher efficiency of the single screw for this vessel it should be noted that the ratio of the disk area of the propeller to the mid-section area of the ship for the twin screw ship is better by 40 percent than the single screw ship, at equal revolutions, and this will affect the maintaining of speed at sea and the maneuvering ability of the ship. The pressure per square inch on the propeller surface, also, in a single screw ship will be higher to the extent of about 25 percent but, as this figure does not exceed five pounds per square inch for 140 revolutions, it is not a serious matter except when the vessel is pitching heavily.

Speeds at Which Single and Twin Screws Are Equally Efficient at Various Revolutions

It has been noted that the curves of the indicated horsepower for the single screw and twin screw vessel intersect at 88 revolutions per minute. A calculation has, therefore, been made to discover at what speed of the twin screw vessel the efficiency will be equal to that of the single screw vessel at 10 knots and various revolutions.

The figures are as follows:

Revolutions	60	80	100	120	140	160
Speed in knots	10.71	10.14	9.91	9.79	9.64	9.43

the twin screw being more efficient above these figures.

Case of Fixed Revolutions and Variable Ship's Speed

In addition to examining this problem for a fixed speed of ship and a series of different revolutions, I have also examined it from the other point of view of fixed revolutions and variable ship's speed, and a diagram giving these results is presented in Fig. 2.

The revolutions per minute assumed were 100 and the wake fraction for single and twin screw ships was assumed as before so that the results are an interesting demonstration of how the speed of the ship at given revolutions affects efficiency. It will be noted from this diagram that on fixed revolutions the single screw vessel shows up better at the higher speeds.

The revolutions of the twin screw engines at various speeds to give efficiencies equal to the single screw engine at 100 revolutions per minute are as follows:

Speed in knots	8	9	10	11	12	13
Revolutions per minute	115.3	111.2	105.6	94.3	89.5	77.0

Both of these comparisons assume that the engine revolutions at 1,000 horsepower and 550 horsepower would be alike, but this is not the case; in general service it is found that the revolutions vary inversely with the square root of the horsepower which would make the revolutions for the smaller engine 135 compared with 100 for the larger. On this basis the indicated horsepower for the twin screw engines has been calculated for both diagrams, and is shown in dotted lines; it will be noticed that the power of the twin screw machinery is approximately 5 percent higher than the single screw through the range of our calculations. I believe this fairly represents the difference in propeller efficiency between the two methods of propulsion, but, as already pointed out, a choice of revolutions per minute cannot be made solely on the question of lowest indicated horsepower because, in reducing revolutions, weight, first cost, cost per deadweight ton, and interest charges go up, and deadweight carrying capacity drops as well as fuel consumption, and it is a question of ship economy as to what revolutions should be accepted.

The utility of these diagrams can be very much increased when it is remembered that the pitch ratio and propeller efficiency is constant for the same revolutions squared, multiplied by horsepower and divided by speed of advance to the fifth power $\left[\frac{R^2 \times H}{V^5}\right]$, and propeller diameters vary with the speed of advance divided by the revolutions.

Examples

One or two examples of the use of this diagram may be given:

(1) Assuming a speed of 10 knots and 1,000 effective horsepower, at what revolutions would a single screw electrically driven engine require to run in order to give efficiencies equal to a pair of twin screw Diesel engines running at 130 revolutions per minute, the efficiency of the electric drive being taken as 90 percent? From diagram I the twin screw outfit consumes 2,700 indicated horsepower, therefore the equivalent power for the single screw Diesel drive will be 2,700 multiplied by 0.90, equal to 2,430 indicated horsepower, and from the diagram the electric motors will have to run at a speed of 74 revolutions per minute, the respective propeller diameters being 11 feet 6 inches and 18 feet 2 inches.

(2) Apply diagram (1) to a ship of 8½ knots and requiring 420 effective horsepower (bare model) and ascertain whether a single screw at 140 revolutions per minute or twin screws at 175 revolutions per minute would be more economical in power.

As $\sqrt{\frac{R^2\,H}{V^5}}$ is constant for equal efficiencies the revolutions on the diagram should be increased in the ratio $\sqrt{\frac{420}{1000}} \times \left(\frac{10 \times .747}{8.5 \times .747}\right)^{2.5}$ i.e. by 1.0277.

Then read revolutions $140 \times 1.0277 = 144 = 2{,}820$ indicated horsepower and $175 \times 1.0277 = 180$ revolutions per minute and by exterpolation we read 2,915 indicated horsepower for twin screws, or correcting these figures for this proposal $\frac{420}{1000} \times \begin{cases} 2820 = 1184 \\ 2915 = 1224 \end{cases}$ and the twin screw

$$\underline{} \; +40$$

ship would require 40 more indicated horsepower than the single screw ship equal to, say, 30 tons of oil fuel per annum.

At 140 revolutions per minute of engines = 14.4 on diagram, diameter = 13.0 feet.

Pitch = 9.25 feet and, as these vary as $\frac{V}{R}$, the new diameter and pitch would be—

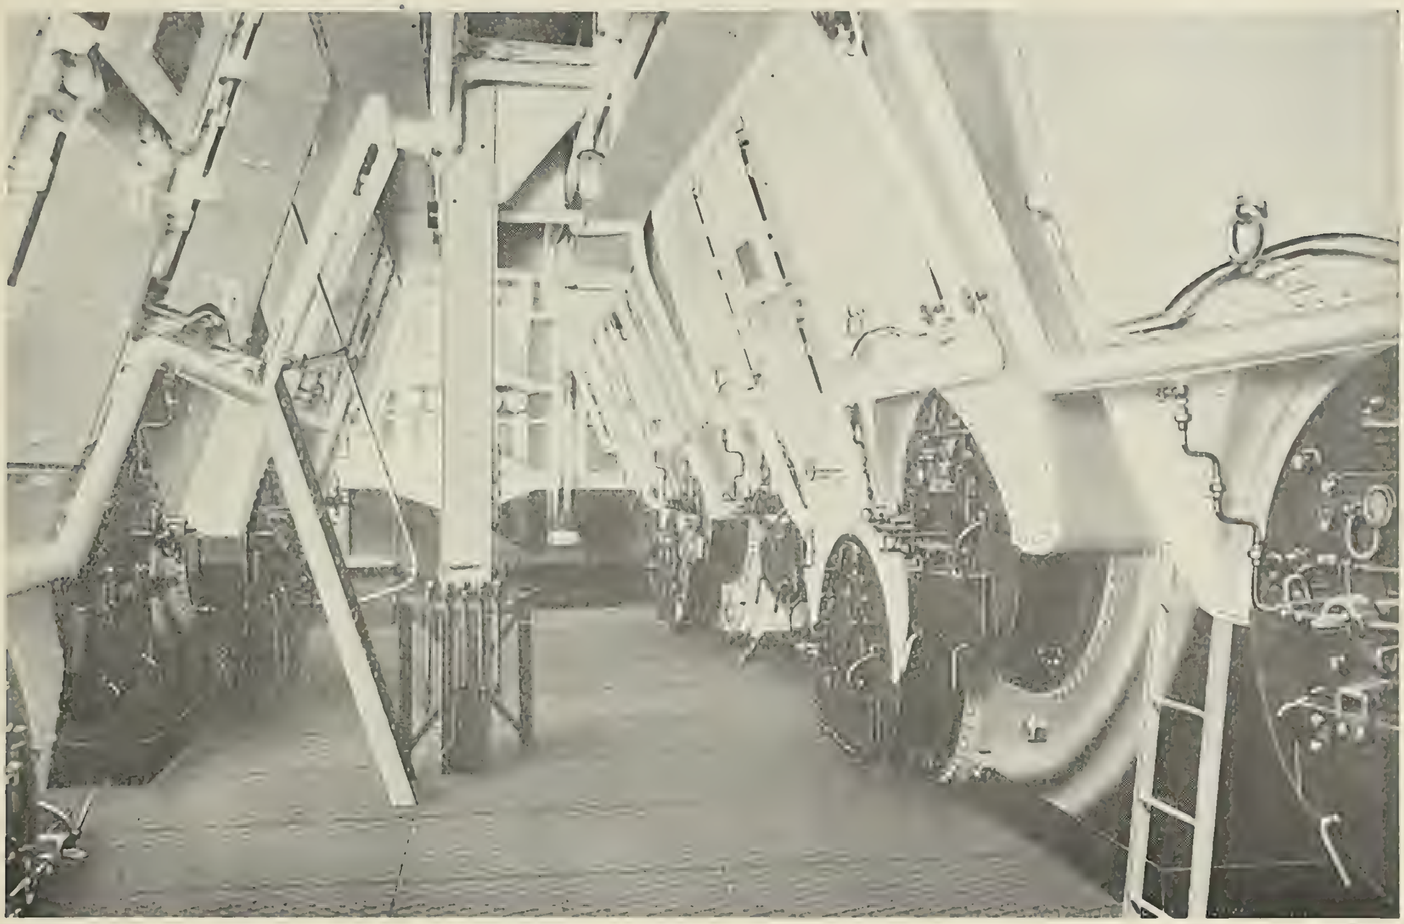
$$\text{Diameter} = 13 \times \left\{ \frac{8.5}{10.0} \times \frac{144}{140} = .8742 \right\} = 11.36 \text{ feet.}$$

$$\text{Pitch} = 9.25 \times .8742 = 8.08 \text{ feet.}$$

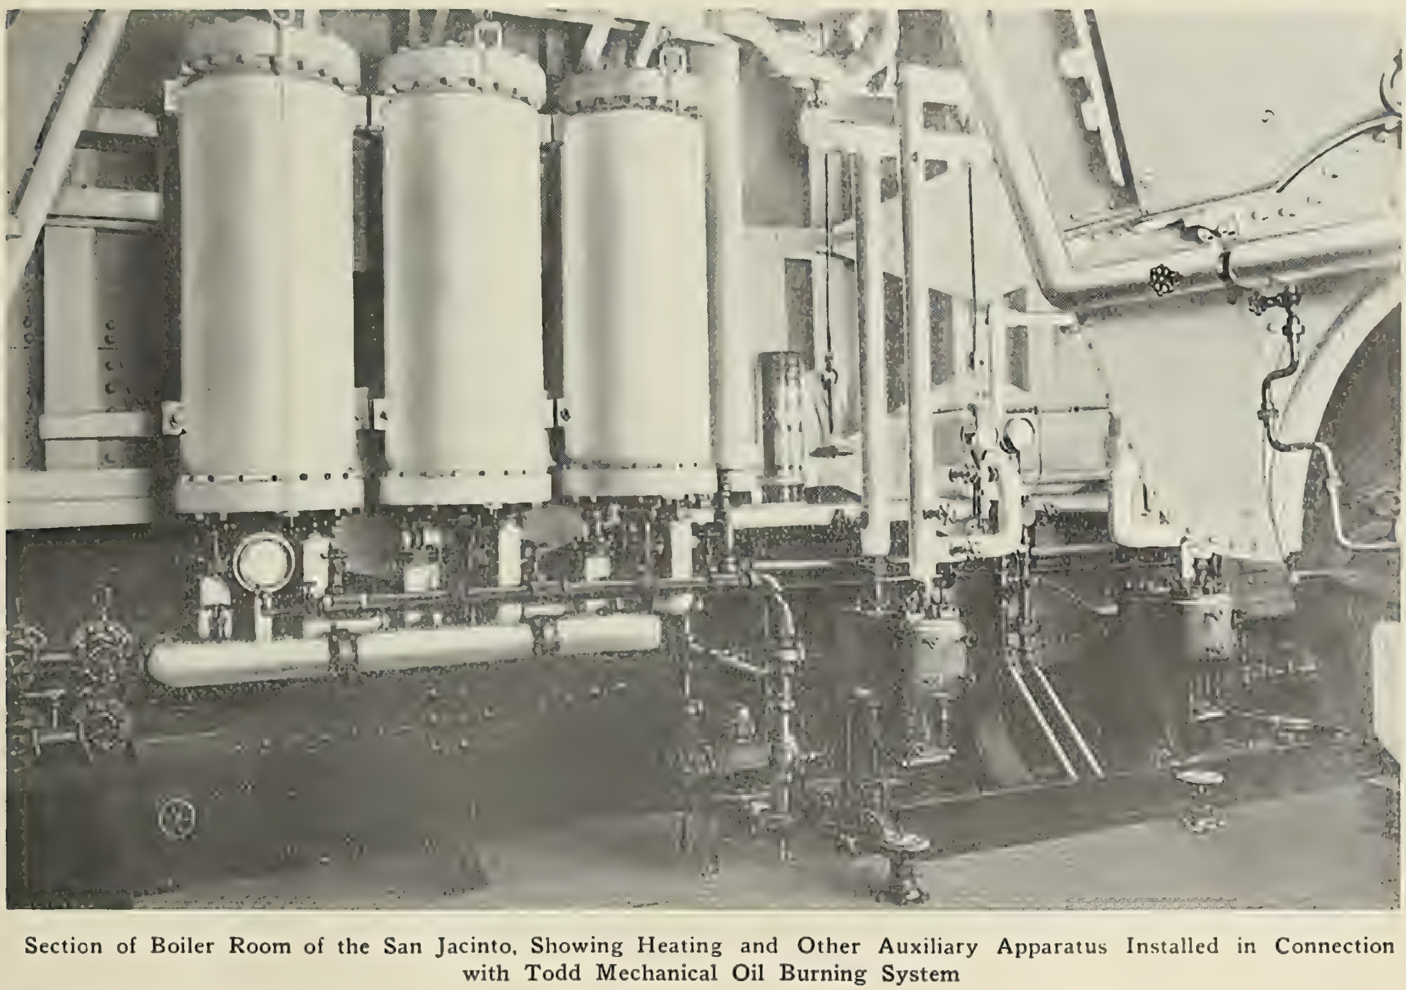
Todd Oil Burning Equipment to be Installed on Passenger and Freight Vessels

Contracts for the installation of mechanical fuel oil burners in twelve passenger and freight vessels have recently been awarded to the Todd Shipyards Corporation. These vessels, totaling 78,100 indicated horsepower, include the *Empress of Scotland* of the Canadian-Pacific Steamships, Ltd.; the *Calamares, Pastores, Limon, Esparta* and *San Jose* of the United Fruit Company, the *El Cid, El Siglo, El Dia* and *El Rio* of the Southern Pacific Company and the *City of Jacksonville* of the Mallory Line.

The work on the five fruit steamers and the Red Star liner *Kroonland,* which is being fitted with Todd mechanical



Boiler Room of Mallory Line Steamship San Jacinto, Showing Installation of Todd Mechanical Oil Burners



Section of Boiler Room of the San Jacinto, Showing Heating and Other Auxiliary Apparatus Installed in Connection with Todd Mechanical Oil Burning System

oil burners in place of an older type system that was installed some time ago, is being carried out at the plant of the Robins Dry Dock and Repair Company in Brooklyn. The remaining vessels of the United Fruit Company and the *City of Jacksonville* are being converted at the plant of the Tietjen and Lang Dry Dock Company in Hoboken.

The accompanying illustrations show the firing aisle and fuel feed tanks of the *San Jacinto* which was recently completed. An excellent idea of the appearance of the oil burning equipment in a finished installation may be gained from the work on the *San Jacinto*.

The *Empress of Scotland* will be fitted with Todd burners on her next arrival at an English port by Todd Oil Burners, Ltd. of London. She was formerly the Hamburg-American liner *Kaiserin Auguste Victoria* of 24,581 gross tons. There are fifty-one furnaces in this vessel and the decision of her owners to replace her oil burners with Todd mechanical equipment followed the successful performance of the Canadian Pacific Steamships, Ltd., new liner *Montclare*. This vessel was equipped with this type burner before she left the yards of her builders, the John Brown Company at Clydebank, Scotland.

Newport News Yard Has Plant for Producing Navy Standard Paint

FOR a number of years the Newport News Shipbuilding and Dry Dock Company has been manufacturing Navy standard bottom paint according to Navy specifications for use on all Government vessels built at the plant. The plant in which the manufacture of paint is carried on consists of the manufacturing shop in which are installed stone and iron mills and agitators. This shop has a capacity of 800 to 1,000 gallons of paint per day. Adjacent to the paint shop is an oil storage building where the various mixing oils are stored. A third section contains the marking and storage departments in which the finished products are handled. Here also is located the shipping department from which paint sold to outside firms is distributed. This section completes the paint plant.

Mixing Department of Paint Plant

During the past year the Newport News Shipbuilding and Dry Dock Company was awarded the United States Shipping Board paint contract for all ports from Newport News, Va., to Galveston, Texas. The specifications for this paint were identical to the Navy standard formula. In addition to the other products of this plant, the company has put a marine bottom paint on the market for which the producers claim high quality, durability and reliability at a moderate price to shipowners and operators. This paint, known as Newport News Shipbuilding and Dry Dock Company's composition, is marketed at all ports along the South Atlantic and Gulf coasts.

A great deal of the paint being used in connection with the reconditioning of the *Leviathan* has been manufactured at the paint plant of the shipyard.

In addition to the production of marine bottom paints, the Newport News paint plant also manufactures a variety of other marine paints, including topside paints, copper paints and hold paints.

H. M. S. **Ark Royal**, the British Navy's latest seaplane carrier, photographed at Weymouth. On the forecastle can be seen two cranes (lowered), which are used to hoist the machines when they alight at sea.

Recent Developments in Marine Insurance

Modified Hague Rules Endorsed—Possible War Blockade Causing Insurers Anxiety—Protection Clause Against Bootlegging Operations

By "Bordereaux"

IT is, perhaps, well to understand the exact attitude of American marine underwriters with respect to carriage of goods by sea, as represented in the recommendations by them to the American conferees at the recent international meetings at London and Brussels. In this country the Hague Rules became much more acceptable to insurance men when disguised by the amendments made by the Imperial Shipping Committee, and the American Institute of Marine Underwriters unanimously voted the amended proposals as "a substantial improvement upon the rules as formerly drawn, and that those rules, as so amended, represent a desirable improvement upon existing law." But the Institute felt that our conferees should urge a few additional changes, the substance of which was as follows:

1. That the rules be extended to include "on deck" cargoes.
2. That the rules should be made to apply to cargo so long as it is in the custody of the carrier and not merely while waterborne.
3. That the notice clause should be amended so any notation of loss or damage on receipt given to carriers should be deemed sufficient notice of claim.
4. That the carriers should be exempted from losses occasioned by fire only when such fire is not caused by design or neglect of the carrier.

With respect to the third proposed amendment it should be borne in mind that our courts have held that notation of damage on receipt given by consignees to carriers does not constitute an actual notice of claim, and there seemed to be no serious objection to the amendment as suggested by the Institute.

There is no doubt that if these rules are to be useful they should be made mandatory. The Institute's thought is that ultimately treaties will be entered into by the various maritime countries, and such treaties will have the effect of making these rules mandatory in the case of all bills of lading issued in such countries.

War Risk Conditions

WAR risk coverage is again to the fore, owing to the serious disturbance in the Near East and a reasonable apprehension that it may develop into something more widespread and grave. Underwriters are quoting war rates to Greek ports at ½ percent, and to Constantinople at 2 percent, subject to forty-eight hours' acceptance. Greek and Turkish vessels are excluded from these rates. War risk, in the New York market, is placed under a form of cover which limits the protection to "waterborne only," and underwriters are reluctant to extend this form to cover property while on shore. The risk of strikes, riots and civil commotions is, of course, covered on shore, but this protection does not include damage or destruction from the acts of organized warfare.

The possibility of a blockade is causing insurers anxiety because this would oblige vessels to discharge at other than the port of destination; and this involves expense of a nature that underwriters do not feel liable for under the war risk clauses, but nevertheless one that they frequently defrayed during the recent war.

The language of the war clause employed by the great majority of American underwriters reads as follows: "Excluding claims for delay, deterioration and/or loss of market, and warranted not to abandon in case of capture, seizure or detention, until after condemnation of the property insured, nor until sixty days after notice of said condemnation is given to these insurers. Also warranted not to abandon in case of blockade, and free from any claim for loss or expense in consequence of blockade, or of any attempt to evade blockade, but in event of blockade to be at liberty to proceed to an open port and there end the voyage."

The frustration clause is another thorn in the side of the underwriter. A large number of banks are declining to accept policies covering war risks, if this clause is included. The argument of the banks is that one of the really serious elements of the situation is the possibility of our Government refusing to permit vessels to sail for the war zone. Subsequent to the *Sanday* decision by the British courts this clause came into general use, despite the fact that that case did not directly involve underwriters. The position of the insurers is that whereas they are willing to cover against the acts of belligerents they do not care to assume liability for losses arising out of the imposition of a government embargo against the sailing of vessels to the Near East. They feel that the banks are already abundantly protected through their rights against the cargo.

Still another source of apprehension is the possibility of shippers making use of a route via Trieste with subsequent transshipments by rail from that port. This involves extra hazards and the likelihood of additional claims and is a situation not contemplated in the original undertaking.

In this connection it is interesting to note that a number of underwriters are making use of an altered war clause that conforms to the requirements of a recent British court decision with respect to liability for seizures of the property of the assured by de facto governments, the latter not being governments in the meaning of the clause. The recent changes are here given in italics: "Including direct loss and/or damage caused by strikers, locked-out workmen or persons taking part in labor disturbances, riots, civil commotions or explosions, the result of unlawful acts, but, notwithstanding anything to the contrary, either expressed or implied herein, or in the policy to which this endorsement is attached, this insurance does not cover and is hereby warranted to exclude claims for delay, deterioration or loss of market, or for confiscation or destruction by the Government, *and/or de facto Government,* of or within the country in which the property is situate and/or the Government, *and/or de facto Government of seceding or revolting States.*"

Portuguese Revolution Coverage

REQUESTS have been coming in to underwriting offices for insurance against the hazards of revolution in Portugal, and they have chiefly arisen through the insistence of certain banks for protection of this character. Inquiries among steamship lines operating to Portugal and an interview with the Portuguese consul have failed to elicit any information as to why this sudden demand should be made, but shippers must secure the coverage their banks demand. There is a general lack of confidence in the stability of the present Portuguese Government and this is

somewhat accentuated by the continued depression of Portuguese currency and the recent passage of a very stringent tax law. The insured should bear in mind that the strike and riot clauses most commonly in use in this market do not include the risk of revolutions unless the latter is specially inserted. Underwriters feel that it would be a mistake to include in their general strike and riot clause the risk of revolutions, this being a hazard of much more serious nature than either strikes or riots, and ought to be dealt with separately. The ordinary war clause does not cover on shore, and that is where most damage from a revolution would most likely occur; nor is it certain that damage on sea by revolutionists would be covered inasmuch as such acts would not be committed "in prosecution of hostilities between belligerent nations." Current quotations for insurance against the results of revolutions in Portugal, as applied to shipments, vary from an eighth to a quarter percent.

Bootlegging Hazards

In these days of wholesale bootlegging and rum-running underwriters are obliged to give careful consideration to hazards thus involved. Suspicion attaches to the surprisingly numerous applications for coverage on yachts and other vessels operating to and from the West Indies. It is believed by underwriters that the warranty as regards illicit and prohibited trade is sufficient to relieve them in the case of most vessels, and that they are further protected against confiscation by the warranty applicable to seizure, arrest, restraint, etc. In the case of yachts, which are so frequently mediums of bootlegging, the restriction that they are to be used for pleasure purposes only, it is felt, is a sufficient protection to the insurer. The illicit trade warranty reads as follows: "It is also agreed that the property be warranted by the assured free from any charge, damage or loss, which may arise in consequence of a seizure or detention, for, or on account of any illicit or prohibited trade, or any trade in articles contraband of war."

W. D. Winter, in his work on "Marine Insurance," says, in this connection:

"It would also appear that there must be read into this clause 'loss—which may arise—for, or on account of any—trade in *the goods hereby insured,*' otherwise an innocent shipper might be prejudiced by the seizure and detention of his goods merely because they happened to be in the same vessel with other goods liable for seizure or detention on account of illicit, prohibited or contraband trade."

Carriers' Liability in Italy

The Merchants' Association of Genoa recently entered into an arrangement with a number of Italian steamship companies with regard to shortweight in shipments of coffee from Brazil to that port. The arrangement is as follows:

1. Damaged and undamaged bags weighing at least 58,500 kilograms do not call for any claim. If the bags weigh less than 58,500 kilograms a shortweight indemnification will be admitted.

2. For bags showing shortweight the difference in weight will be calculated on the basis of 59,000 kilograms. On the same basis there will also be calculated the difference existing between the weight ascertained when goods are shipped and the weight at the time of discharge.

3. For shortweight thus ascertained steamship companies surrender to consignees as indemnification the net remainder of the loose quantity on board.

4. In case the loose quantity in question is not equal to the entire shortness, the steamship company pays 50 percent of difference in weight according to invoiced original price.

5. Steamship companies, as well as consignees, are engaged to provide the necessary supervision so that all the loose coffee on board and in the lighters is gathered, weighed and delivered to the warehouse of the freeport.

6. The weight of bags with shortweight has to be ascertained within eight days after completion of discharging, for shipments up to 6,000 bags; this period will be extended by one day for every full or commenced lot of 1,500 bags more.

7. This arrangement is in force until revoked and has retrospective effect for steamers which have entered Genoa on or after October 1, 1922.

Insurance of License Suspension

They are doing a land-office business in England in the insurance of British sea-going officers against the risk of a suspension of their licenses. This is a new proposition. Policies are being issued by the Navigators and General Insurance Company. For an annual premium of 12s. 6d. the company guarantees the assured during suspension the payment of a monthly sum equaling his monthly salary, and also a full allowance for food, accommodation and attendance of a nature identical with that provided the policyholder at the time of his suspension. The maximum monthly payment is £50.

British Hull Market Active

There is a revival of activity in hull coverage in England at this time. Renewals are coming in briskly and, what is of more significance, vessels are being freely written whose insurance does not expire for several months. This is taken as indicating that owners regard prevailing conditions as advantageous for placing their risks. It would appear to suggest either that an impression is at large that rates are likely to advance with the end of the year, or that the market has reached its bottom and that nothing is to be gained by further delay. Underwriters welcome the business, both because it places them on a sounder basis and because it is taken as indicating that shipowners have faith in their ability to keep their vessels employed.

The Sold Wooden Ships

It has been a matter of gratification to underwriters that the contract under which the 226 wooden Shipping Board vessels were sold requires "that they are not to be used for transportation purposes as steamships, and that they will be promptly dismantled within a reasonable time, after the legal documents have been executed." There is rejoicing in underwriting offices that at last the hour is at hand when insurance companies are no longer to be threatened with extinction for their unwillingness to insure these undesirable risks. By the contract of sale they may be used as barges, but past experience has demonstrated that in most instances the hulls are too heavy for that purpose.

Hazards in Use of Extra Ports

If additional evidence is required to sustain the position of underwriters that serious extra hazards are involved in the use of additional ports in the passage it is at hand in the case of a steamer that recently sailed from New York for Batavia and deviated via Jacksonville, Fla. On coming out of Jacksonville, she grounded, necessitating her being sent to Newport News for repairs, thus entailing substantial extra expense upon her underwriters in addition to opening the average warranties. Following the heavy losses sustained by underwriters in the deviations made by the steamers *Welsh Prince* and *Jethon,* it is felt that every justification exists for additional charges for the use of ports on the passage.

Line Shafts for Marine Internal Combustion Engines

By Joseph Hecking*

This article is an analysis made in connection with the revision of the rules of the American Bureau of Shipping for line shafts of internal combustion engines. It will be found of special interest in cases of contemplated conversion from steam to oil engine drive as it shows the flywheel effect and the cylinder sizes and arrangement suitable for retaining existing shafting. In this connection the reader is also referred to Mr. Hecking's article on "Diesel Engine Crankshafts," published in our February, 1921 issue.

THE turning efforts of reciprocating oil engines are subject to wide variations during the period of a cycle. The variations or the ratio of maximum to minimum turning effort is greatest for one-cylinder engines and decreases with the increase in number of cylinders. In order to bring the cranks over the dead centers and over the period when no positive turning effort is produced the fitting of flywheels becomes a necessity. Without a flywheel and without the flywheel effect of the rotating engine parts, engines would come to a sudden stop at the point of the stroke corresponding to the intersection of the resultant turning effort curve with the zero torque line. Where the resultant torque line does not intersect the zero line the fluctuations in speed would be too great for practical purposes, excepting engines with a large number of cylinders.

It is the function of the flywheel to absorb effort when the turning efforts are above the mean and to surrender the absorbed effort when the turning efforts are below the mean, thus tending to equalize the effects of the irregular turning efforts in their transition to perform work. This theory presupposes that the resistance is uniform during the whole cycle, i.e., that the power developed during the power stroke is uniformly absorbed by the propeller. This is, however, not exactly true, as actual torque diagrams taken from various engines have fully demonstrated. There are a number of other considerations such as misfiring, pre-ignition, torsional vibrations, etc., which make it advisable to calculate flywheels with an ample margin of safety.

Excess turning efforts cause an increase in the velocity of the crankpin, and vice versa. The excess over the mean turning effort causes a maximum velocity near the end of the power stroke, representing the accumulation of the excesses at all the momentary crank angles during this stroke, and the deficiency of turning effort causes a minimum velocity near the beginning of the power stroke. Inasmuch as the power generated is equal to the resistance, the increase in the velocity at the end of the power stroke represents the excess of power E developed during this stroke and is equal to the kinetic energy of the flywheel.

Energy Stored in Flywheel

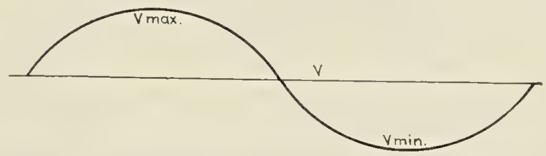
The kinetic energy in foot-pounds stored in a flywheel is approximately:

$$E = \frac{W V^2}{2g} \qquad (1)$$

wherein, W = Weight of flywheel rim in pounds.
V = Velocity in feet per second of the wheel's periphery
g = Acceleration = 32.16

By taking the weight of the rim only and the velocity of the outside diameter in place of the center of gravity the kinetic energy of the wheel is somewhat overrated; but the hub and arms of the wheel, as also the rotating masses of the engine proper, produce kinetic energy which is generally ignored in flywheel calculations. As an additional margin of safety the indicated power has been taken as the basis of calculations, ignoring the friction losses in cylinders and bearings and also the power absorbed by attached auxiliaries. The power delivered to the lineshaft, i.e., the shaft horsepower, is from 70 to 80 percent of the indicated horsepower and the flywheel effect based on rim weight and peripheral velocity is considered to safely cover all conditions.

The fluctuation C above and below the normal velocity of the crankpin, due to the irregular turning efforts, is indicated in Sketch 1. It is evident that the greater the fluctuation the smaller the flywheel effect and the greater the irregularity of the effect of the turning efforts. The kinetic energy to be stored in a flywheel for a predetermined fluctuation depends on the difference in the extreme velocities squared or $V\ max.^2 - V\ min.^2$ This fluctuation C is best expressed in terms of the mean velocity V and may be determined as follows:



Sketch 1.—Showing Fluctuations in Velocity of Crank Pin

$$C = \frac{V\ max. - V\ min.}{V}\ ;\ \text{or}\ V\ max. - V\ min. = C\ V$$

$$\frac{V\ max. + V\ min.}{2} = V;\ \text{or}\ V\ max. + V\ min. = 2\ V$$

$$(V\ max. - V\ min.)\ (V\ max. + V\ min.) = C\ V \times 2\ V$$
$$V\ max.^2 - V\ min.^2 = 2\ C\ V^2$$

Inserting this value in formula (1) the required flywheel effect to produce a required kinetic energy E under a predetermined speed fluctuation C, is

$$E = \frac{W\ 2\ C\ V^2}{2\ g} = \frac{W\ C\ V^2}{g} \qquad (2)$$

If R = Revolutions of engine per minute and
F = Outside diameter of flywheel in feet,

$$\text{Then } V^2 = \left(\frac{F \pi R}{60}\right)^2 = \frac{F^2 \pi^2 R^2}{60^2} = \frac{F^2 R^2}{365}\ ;$$

Inserted in equation (2).

$$E = \frac{W\ C\ F^2\ R^2}{32.16 \times 365}\ ;$$

If W = weight of the flywheel in thousands of pounds

$$E = \frac{1{,}000\ W\ C\ F^2\ R^2}{32.16 \times 365} = \frac{W\ C\ F^2\ R^2}{11.75}$$

E is expressed in foot-pounds, but the diameter and stroke of engines (functions of E) are always expressed in inches. With E in inch-pounds

$$E = \frac{W\ C\ F^2\ R^2 \times 12}{11.75} = W\ C\ F^2\ R^2\ \text{(nearly)} \qquad (3)$$

*Engineer Surveyor, American Bureau of Shipping, New York.

Determination of E for Diesel Engines

The curve of the turning efforts is determined from the indicator card with due consideration of the inertia forces of the reciprocating engine parts. Turning effort diagrams of theoretical or prospective engines are subject to the errors of assumptions and the laying-out of the same requires, therefore, experience and good judgment. Diagrams for general application can only be based on average values and should be checked for each design, especially in cases of material departure from the basic assumption.

Ordinary Diesel engines run normally with a mean indicated pressure of about 100 pounds per square inch piston area, the back or compression pressure considered, and this pressure may be taken as the basis of flywheel calculations. The slight variation in pressures during the exhaust and suction strokes of four cycle engines may be ignored. Based on a maximum working pressure, P, of 500 pounds the mean indicated pressure (m.i.p.) is, therefore, 0.2 the maximum pressure or $0.2\,P$. Assuming that the resistance is uniform, the power developed during the power stroke is uniformly consumed during one cycle, which consists of two revolutions for four cycle engines and one revolution for two cycle engines.

If m represents the mean crank pin pressure per square inch of cylinder area and r length of crank in feet, then $2r =$ stroke S of engine and

$$.2P \times 2r = m \times 2r\pi \times 2$$
$$m = .0318\ P \text{ (4 cycle 1 cylinder)}$$
$$.2P \times 2r = m \times 2r\pi;$$
$$m = .0636\,P \text{ (2 cycle 1 cylinder)}.$$

The mean turning force relative to the crank circle is

$$.0318\,P \times .7854\ D^2 = .025\ D^2P \text{ (4 cycle 1 cylinder)}$$
$$.0636\,P \times .7854\ D^2 = .050\ D^2P \text{ (2 cycle 1 cylinder)}$$

wherein $D =$ diameter of cylinder in inches.

The above mean indicated cylinder pressure is based on the net output of the cylinder. The work done during the power stroke covers, in addition to the uniform propeller resistance, the resistance of the compression stroke. The mean indicated pressure of the latter varies between 40 and 50 pounds per square inch of cylinder area. Taking an average of 45 pounds, the total mean indicated pressure of the power stroke is $100 + 45 = 145$ pounds and the equivalent mean crankpin pressure m during this stroke $145 \times 2r = m \times r\pi$;

$$m = 290/\pi = 92.35 \text{ pounds} = .185\,P.$$

The mean turning force of the power stroke is

$.185\,P \times .7854\,D^2 = .145\ D^2P$ for 4 and 2 cycle engines and the total work done during this stroke based on the crank path

$\left(r\pi = \frac{S}{2}\pi\right)$ is $.145\,D^2P \times \pi S/2 = .228\,D^2PS$.

The uniform resistance of $.025\,D^2P$ (4 cycle) covers a mean length of $.965$ of the power stroke area or $.965\,\pi S/2$ and its work is

$$.025\,D^2P \times .965\,\pi\,S/2 = .038\,D^2PS$$

leaving an excess power

$$E = (.228 - .038)\,D^2PS = .190\,D^2PS \text{ (4 cycle 1 cylinder)} \quad (4).$$

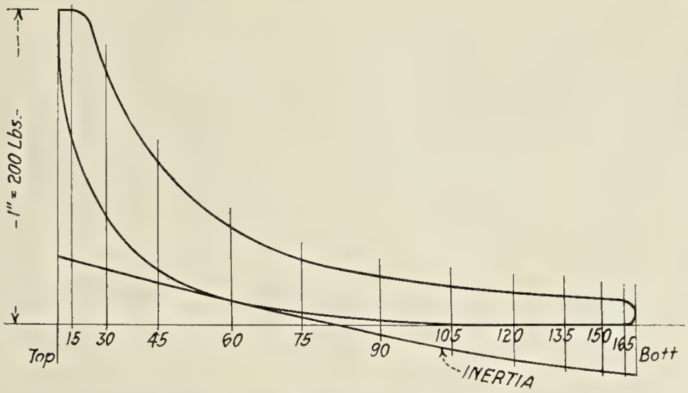

Fig. 3.—Maximum Initial Pressure, 300 Pounds=P; Mean dicated Pressure, 100 Pounds; Mean Compression Pressure, 45 Pounds

The uniform resistance of $.050\,D^2P$ (2 cycle) covers a mean length of $.935$ of the power stroke arca or $.935\,\pi S/2$ and its work is

$$.050\,D^2P \times .935\,\pi\,S/2 = .073\,D^2PS$$

leaving an excess power

$$E = (.228 - .073)\,D^2PS = .155\,D^2PS \text{ (2 cycle 1 cylinder)} \quad (5).$$

E DETERMINED FROM TORQUE DIAGRAMS FOR DIESEL ENGINES

In multi-cylinder engines the work performed by each cylinder is of equal magnitude and the above noted mean

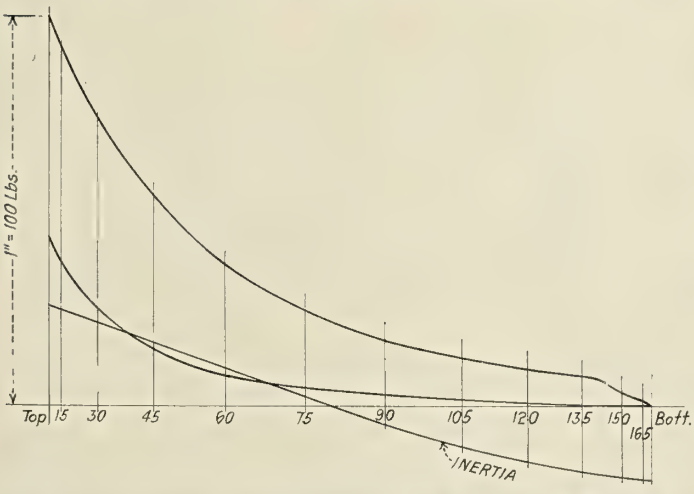

Fig. 2.—Maximum Initial Pressure, 350 Pounds=P; Mean Indicated Pressure, 75 Pounds; Mean Compression Pressure, 25 Pounds

turning efforts of one cylinder may be multiplied by the number of cylinders in order to obtain the combined mean turning effort. It is, however, much easier to determine the excess power by planimetering the excess power area of torque diagrams.

The indicator card in Fig. 1 has the mean pressures above referred to as basic assumptions and the various readings of this card are tabulated in Table I. The torque arm (sixth column) has been determined by the graphical method, described in the author's article in MARINE ENGINEERING AND SHIPPING AGE of April, 1922. The connecting rod/crank length ratio of 4.5 has been used in this analysis as representing the average practice. The seventh column contains the turning moments, being the product of the piston load and the torque arm at the respective crank angle. The last column contains the turning force, i.e., the turning moment divided by the crank length, r. The accuracy of the measurements of the card may be checked by summing the values in the last column and dividing by the total number of crank positions. For a four cycle engine (1 cylinder) the average of the 4 strokes should be $.025\,P\,D^2$ and for the two cycle engine (1 cylinder) $.050\,P\,D^2$ in accordance with the results arrived at above mathematically.

The turning effort diagrams of 4 and 2 cycle engines are shown on Charts 1 and 2 as noted. The abscissæ represent the crank angles for one complete cycle, 2 revolutions for the 4 cycle engine and one revolution for the 2 cycle engine, having one cylinder. The ordinates represent the turning forces at the various crank angles, as given in the last column of Table I. For multi-cylinder engines one complete cycle is covered by the crankpath of $720/n$ degrees in

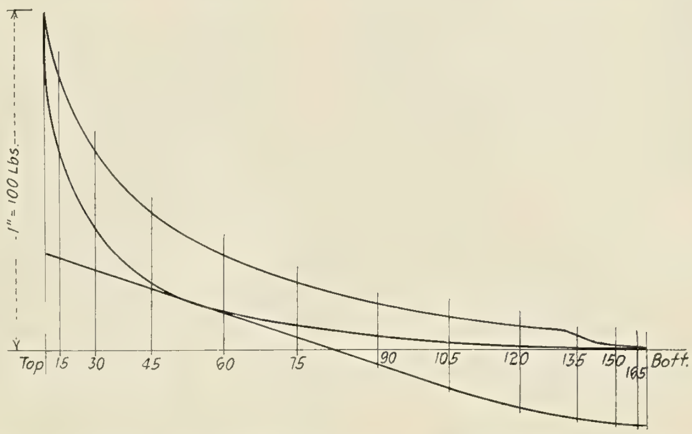

Fig. 3.—Maximum Initial Pressure, 300 Pounds=P; Mean Indicated Pressure, 35 Pounds; Mean Compression Pressure, 32 Pounds

the case of 4 cycle engines and by $360/n$ in the case of 2 cycle engines where n = number of cylinders. Thus a complete diagram of a 6 cylinder 4 cycle engine may be shown on a diagram of $720/6 = 120$ degrees; the turning forces in PD^2 (column 8 Table I) of the various cranks must be combined in their proper relation; i.e., the efforts of 30—150—270—30—150—270 will fall on the same abscissa, marked 30.

The mean turning force line divides the curve into two equal parts, the areas above the mean line are equal to the areas below. Its height above the zero torque line, represents the force in terms of D^2P. Multiplied by the length in terms of $\pi S/2$ gives the work done during one cycle. Thus $.025\,D^2P \times 2r\pi \times 2 = .157\,D^2PS$ is the work of one cycle of a 4 cycle one cylinder engine, and $.050\,D^2P \times 2r\pi = .157\,D^2PS$ is the work of one cycle of a 2 cycle one cylinder engine.

In order to avoid confusion, the curves of the turning efforts of the individual cylinders have been omitted on the diagrams for engines with a large number of cylinders and the resultant curves, shown in heavy lines, have been obtained by adding the proper values in the last column of Table I. The excess energy of the power stroke is the shaded area marked E above the mean turning force line. Its area has been determined by multiplying the mean height

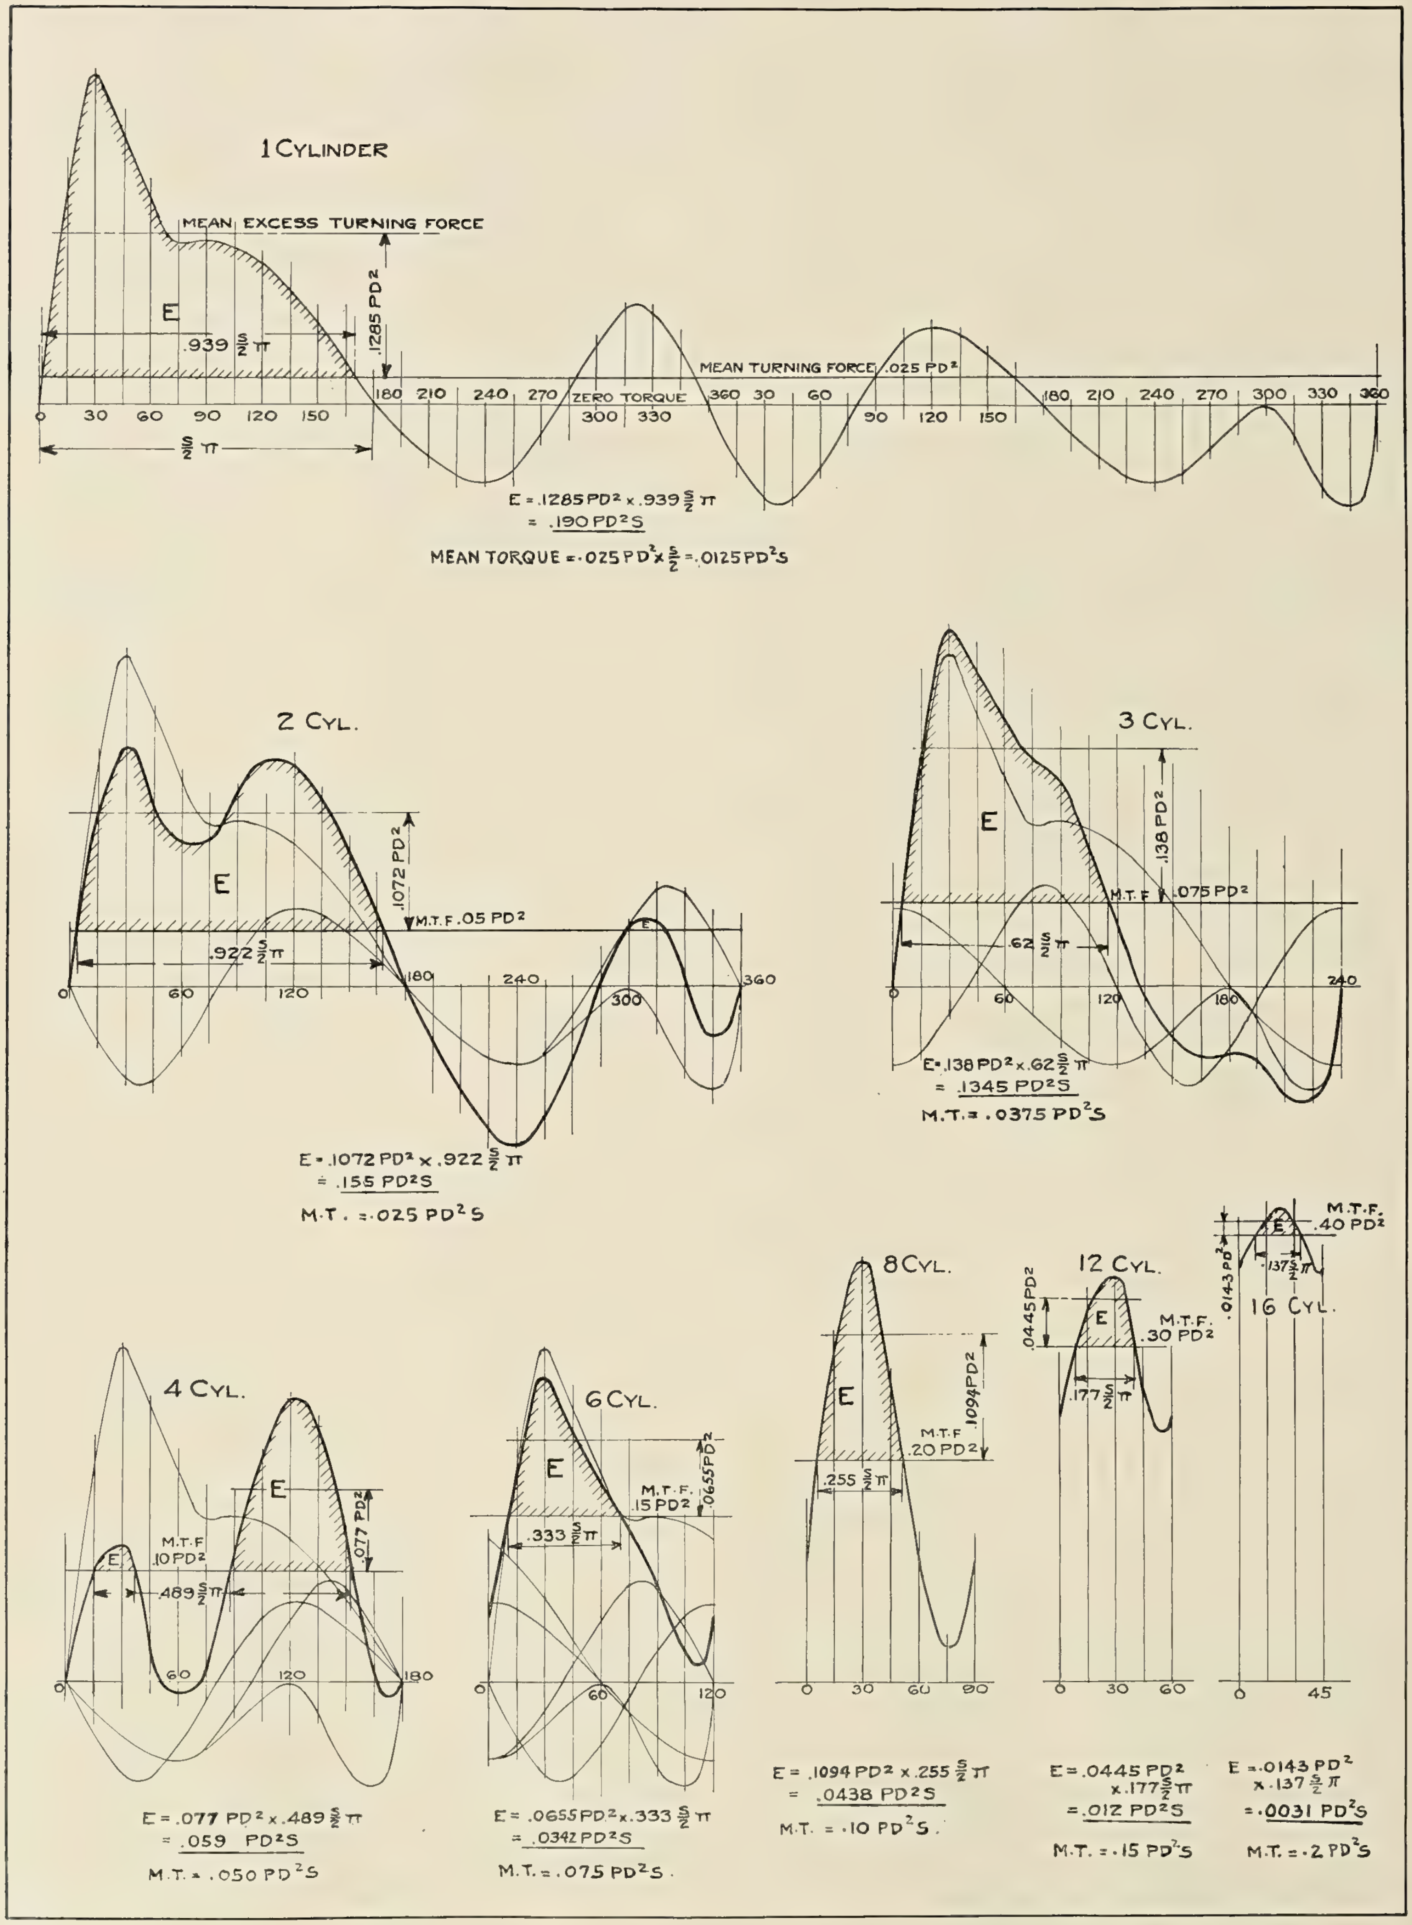

Chart 1.—Turning Effort Diagrams. Four Cycle Diesel Engines

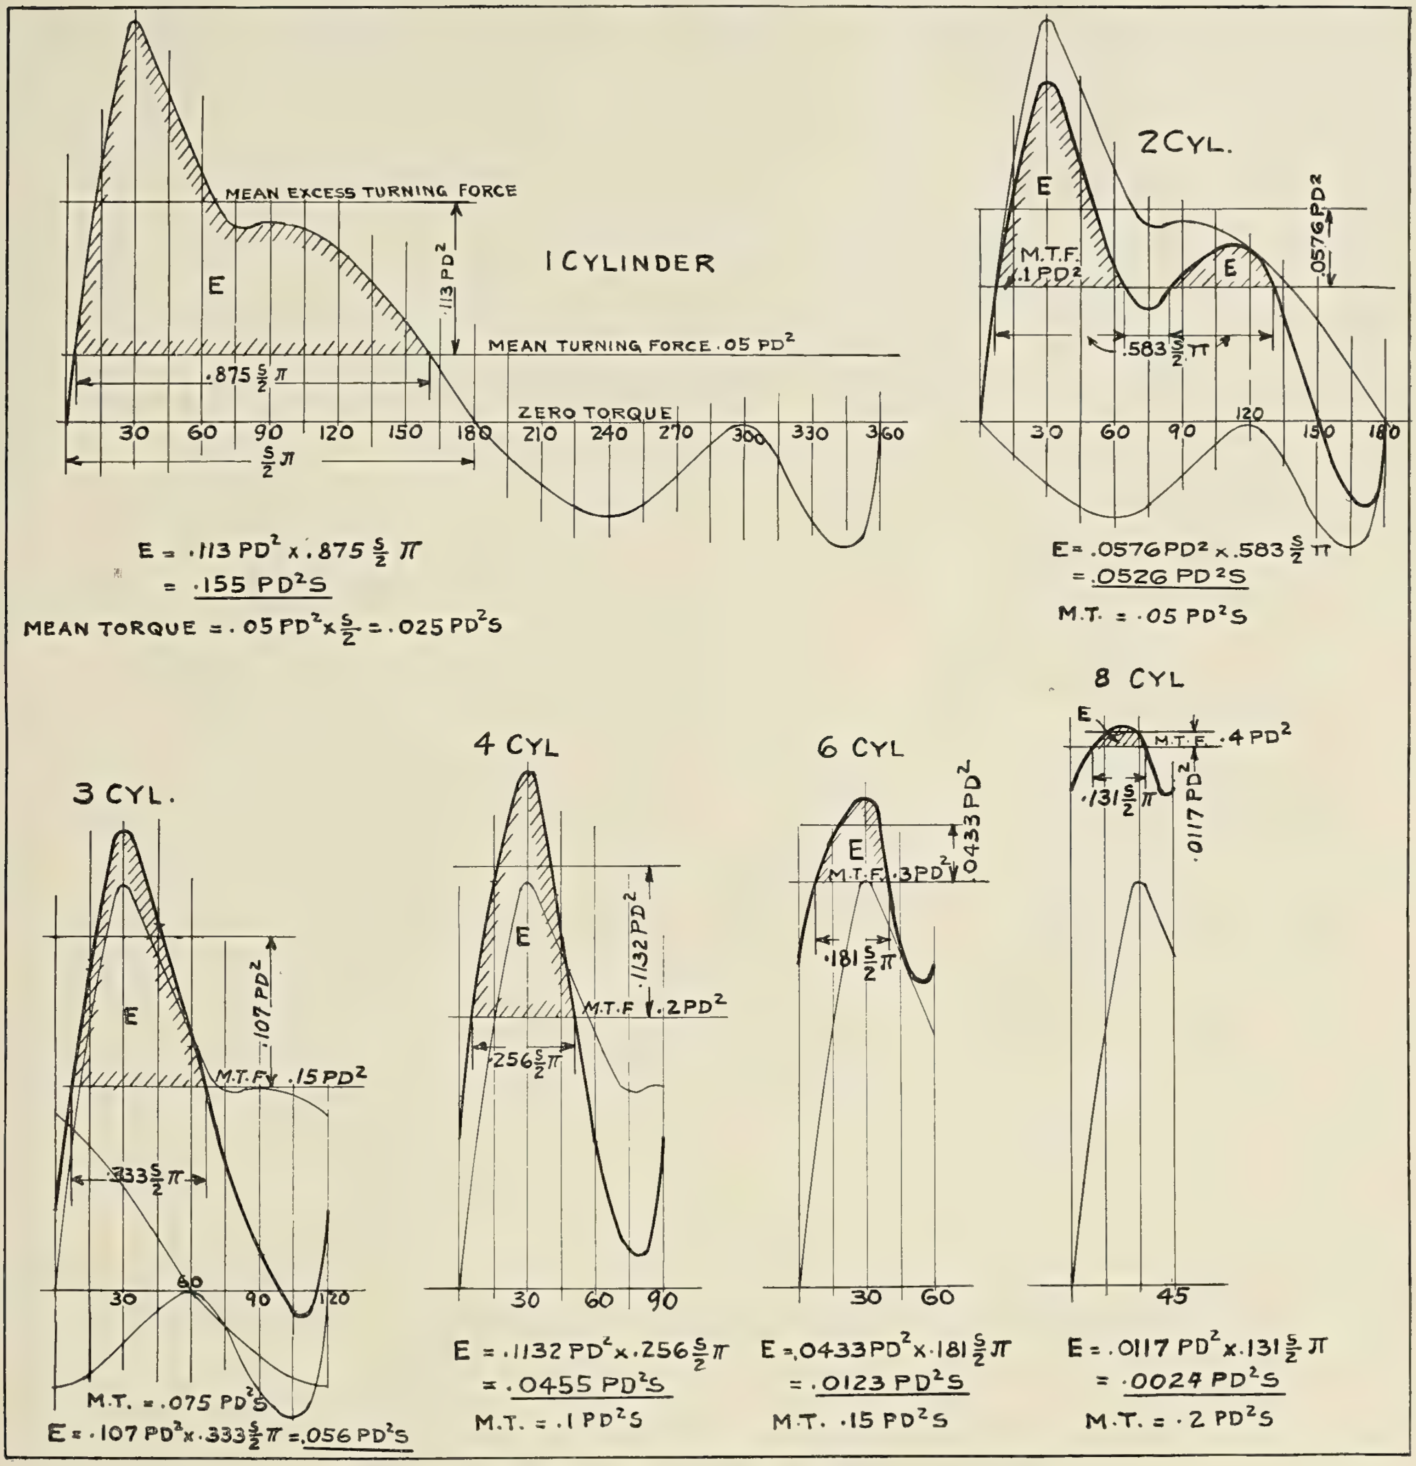

Chart 2.—Turning Effort Diagrams. Two Cycle Diesel Engines

in terms of the piston load PD^2 by the length in terms of the crankpath $S/2\pi$, the product being a percentage of D^2PS or KD^2PS. For general application refinement in the use of the excess area values E is out of order in view of the fact that varying compression and inertia may change the same to a minor degree and the values of K given in the following table may be considered a fair average, being the actual values noted on the charts rounded upwardly, i.e., on the safe side.

Values of K for Diesel Engines

No. of Cylinders	1	2	3	4	6	8	12	16
4 cycle	.190	.155	.135	.060	.040	.045	.015	.005
2 cycle	.155	.055	.055	.045	.015	.005	....	....

By substituting KD^2PS for E in formula 3 the main formula for flywheel effect is obtained

$$KD^2PS = W\ C\ F^2\ R^2 \quad (6)$$

from which the fluctuation C for any existing flywheel or the diameter and weight ($W\ F$) of the flywheel for a desired fluctuation may be determined for any Diesel engine.

Determination of E for Explosive Combustion Engines

The mean indicated and the mean compression pressures for engines other than Diesel type cover a much wider range than those for Diesel engines. The considerable difference is plainly shown by the two indicator cards, Fig. 2 and Fig. 3, the former having a mean indicated pressure of 75 pounds and the latter of 35 pounds, which pressures are not the extreme limits. It is not the scope of this article to discuss the causes and effects of this wide difference in the design of explosive combustion engines. For the purpose of establishing the values of E for the required flywheel effect it is considered advisable to use Fig. 2, which gives

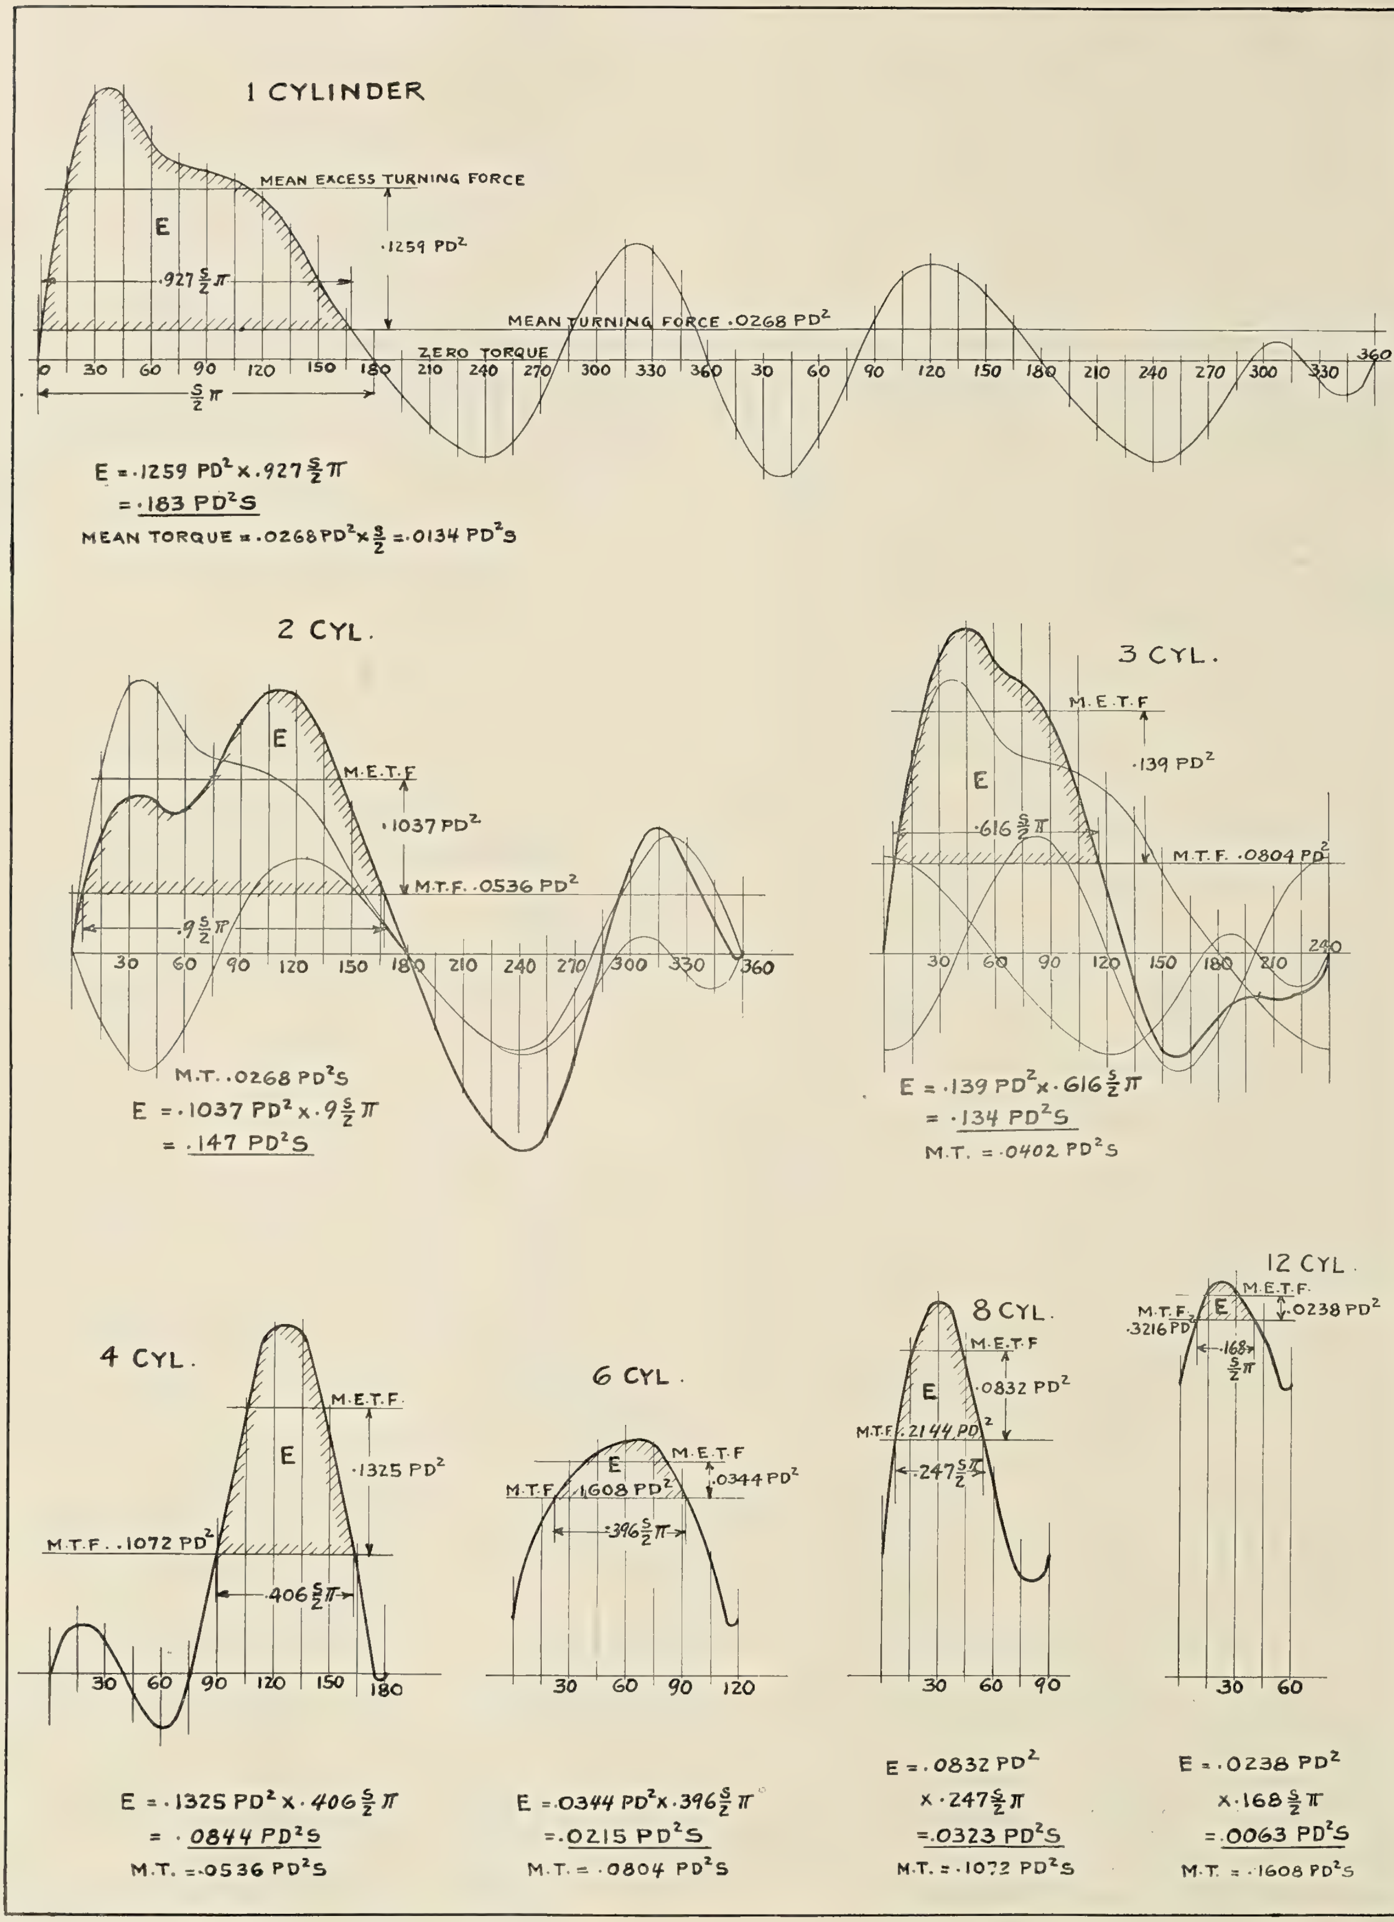

Chart 3.—Turning Effort Diagrams. Four Cycle Explosive Combustion Engines

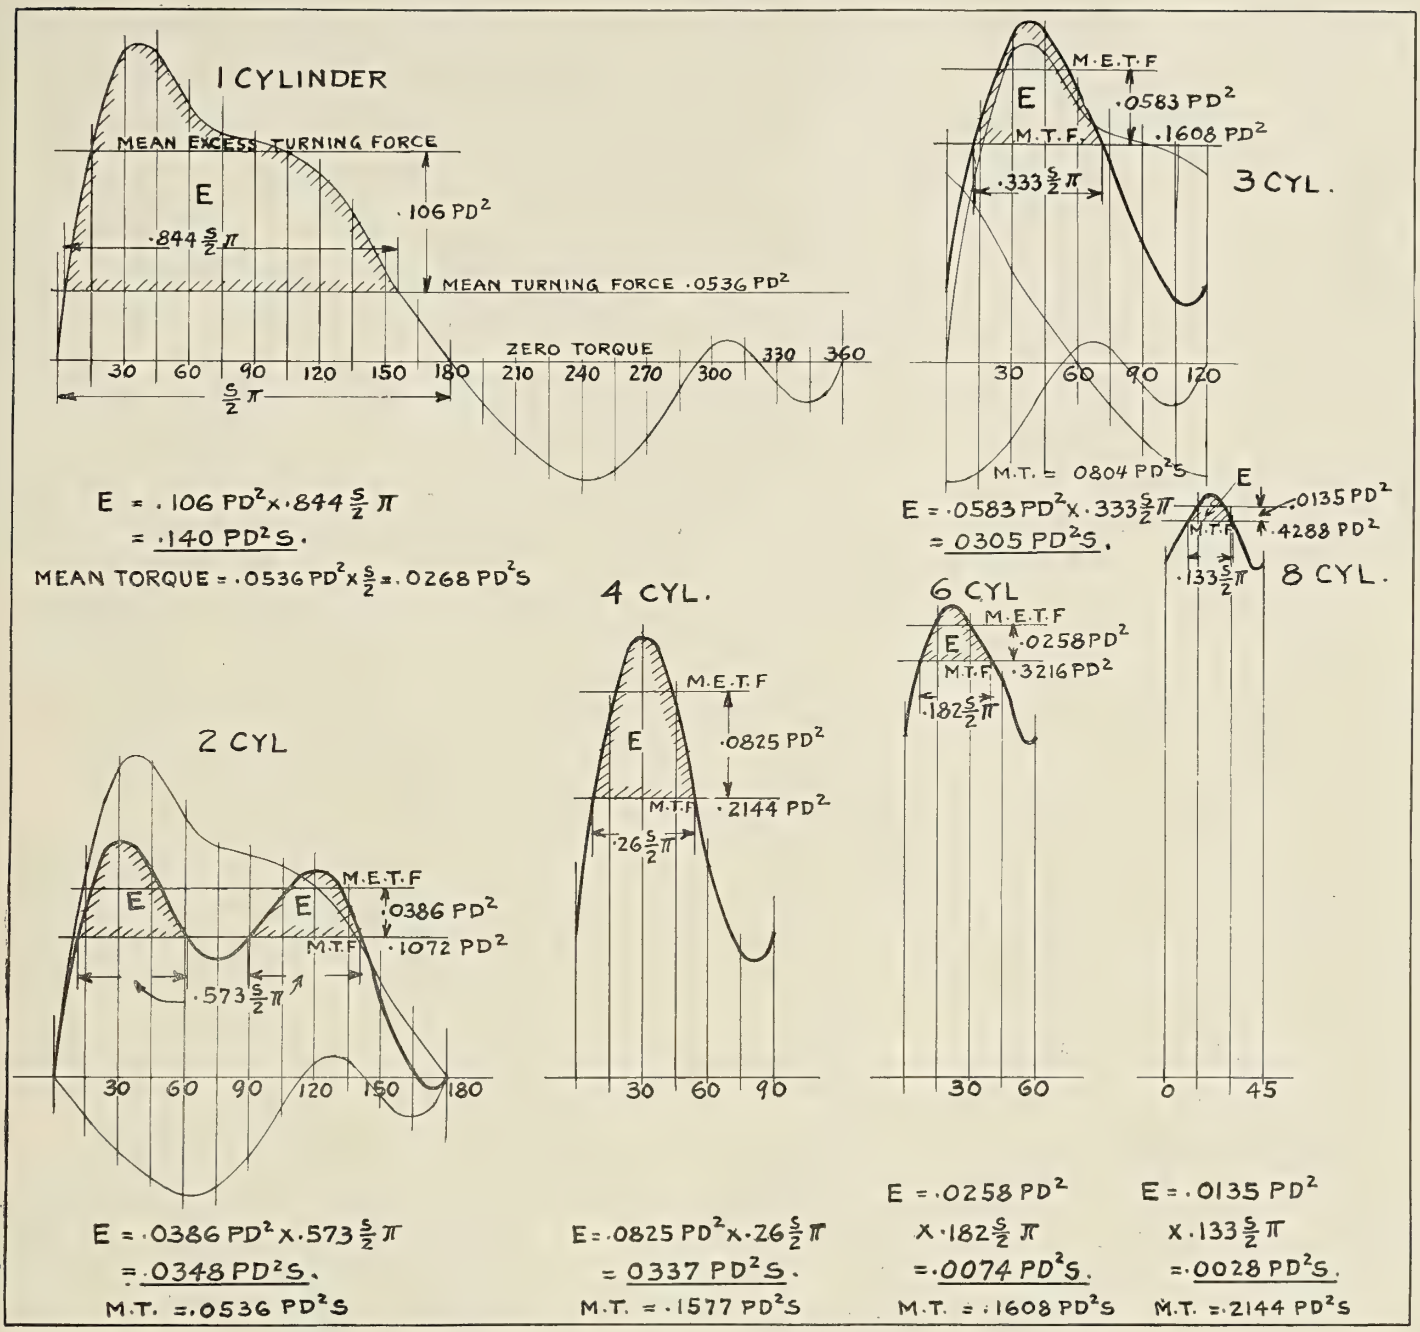

Chart 4.—Turning Effort Diagrams. Two Cycle Explosive Combustion Engine

somewhat larger values. Using the data given in Table II and Fig. 2 the excess area E for one cylinder engines are here briefly analyzed.

Maximum initial pressure P = 350 pounds.
Mean indicated pressure 75 pounds.
Mean compression pressure 25 pounds.
Mean power stroke pressure 75 + 25 = 100 pounds.
Mean crankpin pressure =

$$\frac{75 \times 2r}{2 \times 2r\pi} = 11.94 \text{ pounds} = .0341\ P \text{ (4 cycle)}$$

Mean crankpin pressure =

$$\frac{75 \times 2r}{2r\pi} = 23.88 \text{ pounds} = .0682\ P \text{ (2 cycle)}$$

Mean turning force =

$$.0341\ P \times .7854\ D^2 = .0268\ PD^2 \text{ (2 cycle)}$$

Mean turning force =

$$.0682\ P \times .7854\ D^2 = .0536\ PD^2 \text{ (2 cycle)}$$

Mean crankpin pressure during power stroke =

$$\frac{100 \times 2r}{r\pi} = 63.7 \text{ pounds} = .182\ P$$

Mean turning force during power stroke =

$$.182\ P \times .7854\ D^2 = .1427\ PD^2$$

The excess work of the power stroke =

$$(.1427 - .0268)\ PD^2 \times \frac{S}{2}\pi = .183\ D^2PS \text{ (4 cycle)} \qquad (7)$$

$$(.1427 - .0536)\ PD^2 \times \frac{S}{2}\pi = .140\ D^2PS \text{ (2 cycle)} \qquad (8)$$

E Determined from Torque Diagrams for Explosive Combustion Engines

In the same manner as described under Diesel engines the turning efforts of the indicator card Fig. 2 and Table II, are shown on Charts 3 and 4, for four cycle and two cycle engines. The following table gives the round figures for values of K which may safely be used to calculate the flywheel effect in connection with formula 6.

Values of K for Explosive Combustion Engines

No. of Cylinders	1	2	3	4	6	8	12
4 cycle	.180	.150	.135	.090	.030	.035	.010
2 cycle	.150	.045	.035	.035	.010	.003	....

Effect of Varying Fluctuation on Diameter of Line Shafting

It has been previously stated that the power developed during the power stroke is uniformly absorbed by the propeller. Were it possible for an engine to have a flywheel of sufficient size and weight to absorb all the excess power of the power stroke the fluctuation would be zero and the shaft would be designed for uniform torque. But a glimpse at formula 6 will show the impossibility inasmuch as a zero torque will require a flywheel of an infinite diameter $\times$ weight. The uniform torque may, however, be used as a starting point from which shaft diameters for varying fluctuations can be calculated and the basic formula for this condition is

Shaft torque modulus $\times$ fibre stress = uniform (mean) torque. If d = diameter of shaft and the fibre stress = 5,000 pounds per square inch, $.196\ d^3 \times 5{,}000$ = *uniform torque.*

The uniform torque is the mean turning force noted on the diagrams multiplied by the length of the crank $S/2$. Thus for a 3 cylinder 4 cycle Diesel engine

$$.196\ d^3 \times 5{,}000 = .075\ PD^2 \times S/2 = .0375\ PD^2S$$

$$d = \sqrt[3]{\frac{.0375\ PD^2S}{.196 \times 5{,}000}} \qquad (9)$$

But uniform torque T implies uniform velocity. Energy, however, increases as the increase in velocity squared. The increase in velocity is equal to one-half the fluctuation C as noted in the section on speed fluctuation. If the velocity for uniform torque T is unity, the total torque T_1 for any increase in velocity $= T\ (1 + C/2)^2$. For example, $C = .1$, $T_1 = T\ (1 + .05)^2 = 1.1T$ (nearly). Within the practical limits of C, $(1 + C/2)^2$ is nearly equal to $(1 + C)$ and it will be sufficiently correct to make $T_1 = T(1 + C)$.

Continuing the example of formula (9) for a fluctuation $C = .1$ the torque $.375\ P D^2S$ is increased to $1.1 \times .0375\ P D^2S = .0413\ P D^2S$ and

$$d = \sqrt[3]{\frac{.0413\ P\ D^2S}{.196 \times 5{,}000}} = .595\ \sqrt[3]{\frac{D^2PS}{5{,}000}} \qquad (10)$$

The value under the cube root sign is a constant applicable to engines with any number of cylinders and the numerical value before the root sign a variable depending on the number of cylinders, the cycle, and the fluctuation. It is advisable to retain the fibre stress = 5,000 in the formula in order to permit the ready insertion of a higher or lower stress, depending whether a material of a better or of an inferior quality than the ordinary marine steel of 60,000 pounds minimum tensile strength is used. For material having a minimum tensile strength of 70,000 pounds 5,300 may be used in the place of 5,000. Denoting the variable factor as "b" the formula takes the general form of

$$d = b\ \sqrt[3]{\frac{D^2PS}{5{,}000}}$$

The value "b" may be tabulated as shown in Table IV.

Table IV

Values of b for Diesel Engines

No. of cylinders									
4 cycle	1	2	3	4	6	8	12	16	..
2 cycle	..	1	..	2	3	4	6	8	12
$C = 0$; $T_1 = T$......	.399	.503	.576	.635	.726	.799	.915	1.007	1.153
$C = .05$; $T_1 = 1.05\ T$	.406	.512	.586	.645	.738	.812	.930	1.023	1.172
$C = .1$; $T_1 = 1.1T$...	.412	.520	.595	.655	.750	.825	.944	1.038	1.191
$C = .15$; $T_1 = 1.15\ T$	.419	.528	.604	.665	.761	.837	.958	1.053	1.208

For values of b for intermediate fluctuations it will be sufficiently correct to interpolate between the values given, but it will be more accurate to determine T_1 and solve for b in accordance with formula 10.

In a similar manner tables of b values may be calculated for explosive combustion engines, but on account of the wide difference in the mean indicated pressures, which would necessitate a number of tables for engines of different characteristics another method of calculating shaft diameters applicable to all engines is given in the following—

General Formula for Determination of Line Shaft Diameters

p = Mean indicated pressure (from indicator card or by design).
p_c = Mean turning pressure (crankpin).
r = Length of crank in inches; stroke $S = 2r$.
D = Diameter of cylinders in inches.

$$p \times 2r = p_c \times 2r\pi \times 2$$
$$p_c = .16p \text{ (4 cycle)}$$
$$p \times 2r = p_c \times 2r\pi$$
$$p_c = .32p \text{ (2 cycle)}$$

Mean turning force =
$$.16\ p \times .7854\ D^2 = .125\ p\ D^2 \text{ (4 cycle)}$$
Mean turning force =
$$.32\ p \times .7854\ D^2 = .25\ p\ D^2 \text{ (2 cycle)}$$
Mean turning moment =
$$.125\ p\ D^2 \times S/2 = .0625\ p\ D^2S \text{ (4 cycle)}$$
Mean turning moment =
$$.25\ p\ D^2 \times S/2 = .125\ p\ D^2S \text{ (2 cycle)}$$

Torsional resistance of shaft with fibre stress of 5,000 pounds per square inch =
$$.196\ d^3 \times 5{,}000$$

For 1 cylinder 4 cycle
$$.196\ d^3 \times 5{,}000 = .0625\ p\ D^2S.$$
$$d = \sqrt[3]{\frac{.0625\ p\ D^2S}{.196 \times 5{,}000}} = .683\ \sqrt[3]{\frac{p\ D^2S}{5{,}000}}$$

For 1 cylinder 2 cycle
$$d = \sqrt[3]{\frac{.125\ p\ D^2S}{.196 \times 5{,}000}} = .861\ \sqrt[3]{\frac{pD^2S}{5{,}000}}$$

The torque produced by each cylinder of multi-cylinder engines is of equal magnitude and the value under the cube root may be multiplied by the number of cylinders, N, in order to obtain the combined mean torque;

Thus for 4 cycle engines
$$d = .683\ \sqrt[3]{\frac{pD^2SN}{5{,}000}}$$

The torque varies as the square of the speed. Shafts are designed for maximum torque and the increase in torque T due to the speed fluctuation above normal is

$$T \times \left(\frac{C}{2}\right)^2$$

and the total torque T_1 for any fluctuation $= T(1 + C/2)^2$.

For example: For $C = .1$ the excess speed $= .05$ and the corresponding torque $T_1 = T \times 1.05^2 = 1.1\ T$ (nearly).

Within the customary limits of speed fluctuations C it will suffice to multiply the mean torque value under the cube root sign by $(1 + C)$ in order to obtain the maximum torque T_1.

The final formula will then read:—

For 4 cycle engines
$$d = .683\ \sqrt[3]{\frac{p\ D^2\ S\ N}{5{,}000}} \qquad (11)$$

For 2 cycle engines
$$d = .861\ \sqrt[3]{\frac{p\ D^2\ S\ N}{5{,}000}} \qquad (12)$$

It will be noted that p is based on the indicated power and not on the brake power. In view of the many extraordinary conditions which may occur in the operation of internal combustion engines it is considered advisable to retain this margin of safety. For engines designed for considerable overload a liberal percentage of the overload mean indicated pressure should be considered in the calculations for shaft sizes.

Shafts calculated by these formulæ are considered subject to torque only, such as line shafts. Shafts subject to bending stress in addition to torque, such as for generators, pumps, etc., should be calculated for the equivalent bending moment by the well known formula

$$M e = .35\ B + .65\ \sqrt{B^2 + T^2}$$

Wherein

Me = Equivalent bending moment.
B = Bending moment = $WL/6$.
L = Distance in inches between centers of bearings.
W = Weight, carried by shaft in pounds.
T = Twisting moment, (or T_1) derived as shown above.

The modulus of resistance for bending is $.098\ d^3 \times 5{,}000$.

$$.098\ d^3 \times 5{,}000 = .35\ B + .65\ \sqrt{B^2 + T^2}$$

and

$$d = \sqrt[3]{\frac{.35\ B + .65\ \sqrt{B^2 + T^2}}{.098 \times 5{,}000}}$$

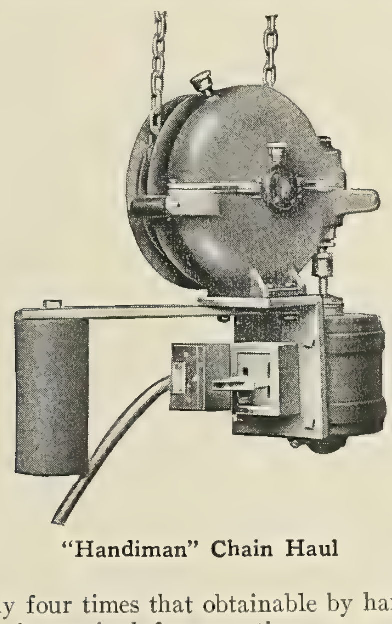
$$= .128\ \sqrt[3]{.35\ B + .65\ \sqrt{B^2 + T^2}} \quad (13)$$

The fibre stress of 5,000 pounds per square inch represents the regular marine steel of 60,000 pounds tensile strength; where material of 70,000 pounds tensile strength is used, 5,300 may be substituted for 5,000.

The author takes this opportunity to express his appreciation for the kind cooperation of the engine builders, notably Worthington Company, McIntosh-Seymour, Standard Motor Construction Company and others to a lesser degree, by placing valuable data at his disposal.

Electric Chain Haul for Hand Hoists

AN electric machine now manufactured by the New Jersey Foundry and Machine Company, 90 West street, New York, will be of interest to users of hand power hoists of 5 tons and larger capacity. This machine may be suspended in the bight of the operating chain and will overhaul 128 feet of hand chain per minute and give a chain a pull of 130 pounds. This permits a load lifting speed of approximately four times that obtainable by hand power and but one man is required for operating.



"Handiman" Chain Haul

Current is supplied to the unit by a flexible conductor attached to convenient sockets or it may be suspended from the hoist if it is more desirable to bring the feeders to that point. The machine is self-balancing, weighs about 160 pounds and can be furnished for operation on either alternating or direct current. Hardened gears are used throughout running in an oil bath.

Public Health Service Requirements for a Sanitary System of Drinking, Cooking and Ablutionary Water Supplies on Vessels

ALL vessels engaged in interstate traffic or handling passengers traveling interstate, or freight which is being transported interstate, are subject to the Interstate Quarantine Regulations of the United States. Special requirements have been prepared for the supervision of the water supplies used for drinking and culinary purposes on such vessels, subject to these regulations. In order that unnecessary and expensive changes, often requiring delay of vessels from their regular business, may be avoided, the following information is herewith prepared for the guidance of naval architects and the managing officials and designing engineers of shipbuilding and repairing companies.

1. If water for drinking and culinary purposes is to be taken by the vessel en route from overboard, it will be necessary that a system of purification be provided, which is satisfactory to the United States Public Health Service. Your attention is invited to page 25, Interstate Quarantine Regulations of the United States, relating to this matter.

2. The storage of water on the vessel for drinking and culinary purposes, either when purified aboard or taken from approved supplies ashore, shall be in tanks of adequate capacity for the needs of the passengers and crew; all tanks shall be of such design that they can be readily and completely drained and flushed, and that the water contained therein will be kept free from exposure to contamination. All possible points where leakage may occur shall be eliminated or designed so as to reasonably minimize the possibility of leakage. The covers of all openings into the tanks shall be watertight.

3. The filling arrangement to such tanks should be so installed as to make it unnecessary that large manholes and other openings be kept uncovered. A small filling pipe provided with a cap should be provided for the purpose of filling the tanks.

4. There shall be no physical connection whatever between the drinking water tanks, pipes, pumps or any part of the system and any other water system on the vessel, or to the sea-cock, bilge pump, fire pump or boiler feed supply (if other than the drinking water is ever used for this latter purpose).

5. The use of storage tanks, containing drinking or culinary water, built in the fore and aft parts of a vessel by placing a bulkhead across the ship and allowing the hull to form part of the tank is strongly discouraged, because such tanks are difficult of access and in case of leakage are subject to potential contamination.

6. In no case shall soil pipes from water closets or drainage pipes of any kind pass through storage tanks containing water for drinking and culinary purposes.

7. There should be no water connections in the kitchens whereby it may be possible to draw water from any but the drinking and culinary water supply.

8. All spigots, faucets or connections whereby it is conveniently available to draw water from other than the regular drinking water supply on board the vessel shall be posted with permanent signs warning that the water is not safe for drinking.

9. Arrangements should be made for the cooling of drinking water on the vessel so that there can be no contact between the water and the cooling ice. This can be most conveniently accomplished by the use of coils in the ice chest.

10. The use of lead pipe in connection with the drinking water system on board the vessel is prohibited.

A. W. MELLON, *Secretary.*

Packing and Gaskets for Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

ON account of the variety of materials and combinations of materials that are made up into packings and gaskets of various kinds and also because of the fact that in most cases packings and gaskets are selected as a result of their past performance rather than on account of the materials of which they are made, the principal value of any article on this subject is the presentation of certain fundamental rules governing the selection of such products.

For past performance, which is so important a factor, the shipbuilder, operator or designer has resort to a number of channels of test and experience in addition to his own accumulated knowledge. One of the most valuable of these is the United States Navy Department, which has lists of approved packings for all of the most important uses. These are subject to change from time to time as new products are tested out and found to be up to standard requirements.

Packings and gaskets are one and the same thing from the point of view of the materials of which they are made and the purpose for which they are used. As purchased, they are all packing except when ordered made up to size and shape for making tight joints between stationary parts, in which case they are called gaskets. As used, the strips or forms of material, cut from sheet packing or otherwise, are called gaskets, except when inserted in stuffing boxes and similar packing spaces in way of moving parts, in which case they are called packing. There are metallic, semi-metallic and "soft" or fabric packings and gaskets and their nature and use can be best shown by dealing with them under the headings of Packing of Moving Parts, Packing of Stationary Parts, Boiler Gaskets and Miscellaneous Packings.

Packing of Moving Parts—Packings

Assembled Metallic Packing

An assembled packing consisting of a container which fits into or against the stuffing box, metal wearing rings, springs to keep the rings against the rod and any other necessary parts, is usually designated merely as metallic packing and is assumed to be required where "metallic packing" is specified on shipboard. Such a packing is the standard for high pressure piston rods and valve rods of reciprocating steam engines. On account of its flexibility it is especially desirable where there is a lack of alinement throughout the length of the stroke. The packing rings are of cast iron or bearing metal, or a combination of both. When properly cared for, the rods are not subject to as much friction and wear as with the so-called soft packings, and the metallic packing is less expensive in the long run.

This packing is particularly desirable for the main engines, the steam end piston rod of main and auxiliary boiler feed pumps, and the piston rod of circulating pump and independent air pump engines. Representative packings of this kind are the Cook, France, Holmes, Katzenstein, Martel, Mitchell, United States and Watson packings.

The writer knows of no assembled metallic packing that will hold water or ammonia without the use of a ring or two of soft packing.

Metallic Packing, Miscellaneous

There are various metallic packings on the market which consist of rings of bearing metal of various shapes and cut in various ways so as to break the joints. They are cheap substitutes for the assembled metallic packing and are of no value for severe duty. They are of value in some cases on small rods and have less friction and cause less wear on the rods than some of the soft packings. They generally require one or more rings of soft packing to make a tight joint and such combinations are proposed for certain services by their manufacturers.

Semi-Metallic Packing

Such packings are usually of bearing metal or lead braided, shredded or in the form of shot. In some cases graphite is mixed with the metal, and in other cases the lead and graphite are made plastic by the addition of bismuth. From their nature they might be called metallic packing, but it is safer to class them as semi-metallic.

They are generally found to be unsatisfactory when used for either rods or slip joints. They melt into a hard, solid mass, frequently leak and are difficult to remove when it becomes necessary to renew them or replace them with some other form of packing.

These packings require one or more rings of soft packing when used to hold water, air or ammonia.

Some of the manufacturers of soft packings produce products which contain bearing metal in combination with other materials, and this is another type of semi-metallic packing. They also produce a braided soft copper wire packing, to be used in combination with fibrous packings for high pressure work.

Soft Packing

Non-metallic packings for the service now under consideration are called soft packing. Their name is legion and their composition and construction very diverse. There are however certain fundamental considerations from a materials point of view which are of value in making a proper selection for any particular service. The packing should be resilient and flexible and retain these qualities under the service conditions, and it should not be of a construction that will allow pieces of it to get loose and work away. Asbestos is the premier material for high heat and is a valuable packing material generally; but it is deficient in elasticity. Rubber gives resiliency but dry heat and oil destroy it. Hemp is too coarse. Cotton is soft and elastic but will not stand heat. Flax is very flexible, but expensive, and will not stand heat.

The most satisfactory soft packings for severe high heat steam service or air service consist of combinations of carefully treated long fiber asbestos which is lubricated with graphite and various compounds, with a rubber cushion that is usually near the back of the packing. Some of these packings which have been found to give good service on shipboard are:

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

Anchor Packing Company	Ankorite Superheat No. 205
Belmont Packing & Rubber Company	Belmont No. 50
Consolidated Packing & Supply Company	Consolidated No. 306
Crandall Packing Company	Helios No. 303
Garlock Packing Company	Garlock No. 150
H. W. Johns-Manville Company	Kearsarge No. 165

For medium or low pressure steam service the cotton duck and rubber packings are satisfactory.

For packing around the stems of valves and similar service braided or twisted asbestos rope packings are satisfactory, but such packings have only a short life around high pressure rods or in steam line slip joints.

Ammonia rods require a specially expansive and resilient packing and in some cases pure rubber rings are used in combination with other packings. For expander and compressor rods some lubricated combinations of rubber and duck have been found satisfactory, such as

Belmont Packing & Rubber Company	Belmont No. 103
Goodyear Tire & Rubber Company	Lubricated Ammonia

This kind of packing will give trouble in case of overheating.

For gas, gasoline and oil, braided asbestos lubricated packings are suitable. Woven flax packings are also satisfactory for cold oil. For inside packed oil pistons the special hydraulic packing referred to under the head of water packings is used.

For cold water and brine service such as pump plungers and rods, stern tube and pipe line stuffing boxes, etc., flax packings are the best. Tucks packing, which is the name for a cotton duck and rubber combination made by a number of the manufacturers, is also good for pump plungers and rods. Alternate rings of square flax and round Tucks packing have been found to give long service in feed pump plungers.

For hot water service the duck and rubber packings as used for medium and low pressure steam are suitable.

Inside packed pistons call for a specially hard durable packing that will not swell from absorption of water, and for this service a packing made of layers of closely woven duck held together with a fine grade of white rubber has been found most suitable. It goes by the name of "hydraulic packing."

For centrifugal pump stuffing boxes and other revolving shaft work, a braided asbestos lubricated packing such as "Palmetto" made by Greene, Tweed & Company has been found to give very good results.

Cotton lamp wicking is of value for cold water service around valve stems.

Packing of Stationary Parts—Gaskets

Gaskets cut from sheet packing are required mainly for cylinder covers and in pipe lines and valve bonnets. They generally range from 1/32 inch to 1/16 inch thick. For steam up to 125 pounds pressure and for water of all pressures 1/32 inch will usually suffice. For steam from 125 to 250 pounds and for oil 1/16 inch is a good thickness. In some cases such as fuel oil suction and oil filling lines gaskets for oil tight work are made ⅛ inch thick of compressed cardboard. Good practice for the gaskets between component parts of pumps, condensers and feed water heaters is to specify a thickness of not less than 1/32 inch nor more than 1/16 inch, and for evaporators and distillers, a thickness of not less than 1/16 inch nor more than ⅛ inch.

Metallic

The metallic gaskets most frequently met with on shipboard are the sheet lead gaskets used about the refrigerating plant installation. Soft copper or lead wire rings are required between the stuffing box and the gland with certain types of assembled metallic packing. The copper is preferable

Compressed Asbestos Fiber

Gaskets of this material are the best for all high heat service including cylinder head joints of steam and internal combustion engines. The asbestos fiber is compressed under great pressure with bonding materials. In some cases one side of the packing is graphited or otherwise treated so that it will not adhere to the joint surface, and the other treated so that it will adhere, thus preventing destruction of the gasket when the joint is taken apart. This results in the two sides being of different colors.

Examples of these sheet packings, or gasket materials, which have given good satisfaction on shipboard are:

Anchor Packing Company	Ankorite No. 425 and Tauril
Consolidated Packing & Supply Company	Consolco No. 500
Crandall Packing Company	Rex Style No. 1920
Durabla Manufacturing Company	Durabla
Garlock Packing Company	No. 900
Goodrich Company	Special Black
Goodyear Tire & Rubber Company	Goodyearite
H. W. Johns-Manville Company	Service Sheet
Johns-Pratt Company	"Red Fibre"
New York Belting & Packing Company	Firo

Woven Asbestos Cloth

This packing is an asbestos fabric with fine brass wire interwoven and impregnated with a special compound. It is an expensive high heat sheet packing that is not as efficient as the compressed asbestos fiber packing. It is necessary where the joint surfaces are rough and uneven. It is particularly suitable for such service as exhaust pipe header flanges. The Johns-Manville Company's "Mobilene" is an example of this kind of packing.

Rubber

Rubber is the ideal gasket material for watertight work about the hull, in watertight doors, manholes, etc., and for washers generally. It cannot, however, be used where oil or gasoline might come in contact with it; so is not suitable for manholes of double bottoms that may carry oil and similar service.

Pure rubber rings are also the approved gaskets between the tail shaft liner and the propeller hub to keep water out of the propeller cavity.

Rubber gaskets are also used in ammonia joint work.

Rubber Compositions

These are of particular value where the leakage of water or brine is to be prevented. They can be obtained plain or with cloth or wire insertion, which add to the life and strength of the packing. Like pure rubber, such packings will not in general stand exposure to heat, oil or gasoline.

The cloth insertion packing is usually furnished in two grades. Grade No. 1 is expensive and is intended for use only in joints which may be expected to last for years. Grade No. 2 is a high-grade packing costing about one-third as much as Grade No. 1 and should be used for all ordinary purposes.

The wire insertion packing should be limited to hot water and low pressure steam joints. High pressure steam gradually burns it out. It is very expensive and in most cases some other type of packing should be used. It is customary on hot water pumps to have the same kind of gaskets on both the steam and water ends.

Examples of rubber composition packing, which have been found satisfactory are:

U. S. Rubber Company	"Rainbow"
B. F. Goodrich Company	"Akron Red Sheet"

Some packings of this character soon crack and deteriorate in a store room.

Wood Fiber

Wood fiber sheet packings are made to resist oil, gasoline and water. They contain no rubber or rubber substitutes

that are soluble in oil or gasoline. Tough oiled paper is an example of thin packing of this kind. Cardboard cut to shape without joint and soaked in a mixture of 10 parts varnish and 20 parts wax makes good gaskets for oil tank manholes. Proprietary packings that have given good service on shipboard are:

Endura Manufacturing Company	Endura
Fibre Finishing Company	Vellumoid
Garlock Packing Company	Garlock No. 680
H. W. Johns-Manville Company	Seigelite

Boiler Gaskets

Boiler gaskets for manholes and handholes or for the tube caps, tube plates and headers of watertube boilers are ordered of the desired thickness made up from templates and are only made from sheet packing or gasket tape in case of emergency. The material is usually the best long fiber woven asbestos cloth, with bronze or brass wire insertion, the layers of cloth being firmly held together by a high grade cement or binder. They should not be loaded with a lot of white lead or other filler. Some special combinations of metal and asbestos have been found satisfactory.

An emergency gasket may be cut from woven asbestos cloth brass wire insertion sheet, but it will not last long and should not be used where exposed to water.

Old boilers cannot use rigid type gaskets and may require thicker gaskets than new boilers.

Gaskets for handholes should be made without joints. Manhole gaskets may have joints covered with tape.

The following list names some of the gaskets which have been found to give good service:

	Handhole	*Manhole*
Asbestos Textile Company		Navy
Belmont Packing & Rubber Company	Belmont High-Pressure	Belmont High-Pressure
Philip Carey Company		No. 751
Crandall Packing Company	Helios	Helios
Danubil Company	Hudsonil	
Durabla Manufacturing Company	Durabla	
Flexitallic Gasket Company		Flexitallic
Johns-Manville Company	Kearsarge (seamless)	Kearsarge (best)
Keasbey & Mattison Company	Battleship	Battleship
Vulcan Asbestos Mfg. Company	Vulcan	Vulcan

Miscellaneous Packings

Canvas

No. 6 canvas painted with red lead on the condenser side and with graphite on the cover side makes a good jointing for main and auxiliary condenser head covers.

Corset Lacing

This is the approved packing for making tight joints around the ends of condenser tubes.

Tar Felt

This is used between sea chest flanges and the shell plating, and similar service. The material is described in the article on "Calking Materials."

Cup Leather

Cup leather packings are sometimes required for the reversing engine and other special service, and are obtainable from the packing manufacturers.

Paste Jointings

Red lead, white lead and other substances in paste form are sometimes used to make tight joints, either alone or when mixed into fibrous materials.

One of the best of these paste jointings is an imported proprietary substance called manganesite. It has been found very satisfactory for turbine casing joints. This material with wire gauze is used between the flanges of boiler mountings and the boiler shell.

The following is a good list of engineer's consumable stores of packing for one ship:

Steam Packing—Quantity

High pressure steam packing, square, spiral, for Main engine piston and valve rods, sizes as needed	2 sets of each
High pressure steam packing, square, spiral, for Piston rods for pumps and deck machinery, ⅜, ½, ⅝, ¾ inch and above, if required	1 box of each
Valve stem packing, asbestos, braided, ⅛, ¼, ⅜, ½ inch	1 box of each
Asbestos tape, 1½ by ⅛ inch	10 pounds
Asbestos tape, 1 by ⅛ inch	10 pounds

Water Packing

Flax or Tuck's, square, for pump rods and plungers, ⅜, ½, ⅝, ¾ inch and above, if needed	1 box of each
Stern tube gland, size as needed	1 box
Cotton lamp wicking, for cold water, in 100 yard balls	5 balls
Corset lacing, for condenser tubes, in 100 yard balls	2 balls

Sheet Packing (Standard Size Sheets)—Quantity

Asbestos fiber compressed, high pressure steam joints, 1-16 inch thick, for—	
Reciprocating engines	10 square yards
Turbines	5 square yards
Compressed wood fiber, for oil joints, 1-32 inch thick	5 square yards
Rubber, wire insertion, for hot water or exhaust steam, 3-32 inch	5 square yards
Rubber, cloth insertion, cold water, 1-16 inch	10 square yards

Special Packing and Gaskets

Asbestos or cup leather, for reversing engine cylinder, as needed	2 sets
Ice machine compressor's rods, as needed	2 sets
Rope, asbestos, twisted, for boxheaders, watertube boilers, ⅜ inch, if needed	1 ball
Gaskets, manhole, boilers, as needed	1 dozen
Gaskets, handhole, for watertube boilers, as needed	100 percent
Manganesite, for turbine joints	10 pounds

Tests of New Pumping Equipment on New York City Fire Boat "James Duane"

TESTS lasting six hours were recently run on the new pumping equipment of the New York city fire boat *James Duane* at the Clinton plant of the Todd Shipyards Corporation.

The tests were under the supervision of the fire commissioner Thomas Drennan and other officials from the fire department and the National Board of Underwriters. The results indicate that the boat will be one of the most efficient fire fighters afloat, having a discharge capacity of 9,800 gallons per minute against a nozzle pressure of 150 pounds.

The new pumps are of the Lea-Courtney centrifugal, single stage, double suction type driven by Westinghouse steam turbines. The tests included the pumping capacity against 175 pounds' nozzle pressure, at which pressure the pumps delivered 7,900 gallons per minute; against a pressure of 300 pounds the capacity was 4,850 gallons per minute. The guarantee called for 9,000 gallons of water against a nozzle pressure of 150 pounds; 7,500 gallons against a pressure of 175 pounds and 3,000 gallons of water against a nozzle pressure of 300 pounds; all of which requirements were exceeded in the trials. In case of necessity in flooding the hold of a ship, the pumps will be able to deliver about 12,000 gallons of water per minute against a nozzle pressure of 90 pounds.

Special Requirements in Design of Marine Machinery

Reliability—Weight and Space—Accessibility—Resistance to Corrosion—Stresses Induced by Movement of Vessel and Vibration—Spare Parts

By Lieutenant Commander C. S. Gillette, U. S. N.*

IT is a matter of common observation that many designs of mechanical and electrical equipment, based on ideas fundamentally sound, and proven by practical experience in shore establishments, fail deplorably when an attempt is made to adapt them to marine installations. It appears certain that a large percentage of such failures could be avoided, if due consideration were given to the special requirements of marine and naval service and an effort made to modify the design to meet such requirements before the marine market is approached.

Of course great merit in any new design will eventually win out and after a sometimes long and painful process of evolution the equipment will finally arrive at a stage of complete suitability for marine or naval use. But the process of evolution could be much shortened and time and money saved by both user and producer, if even a partial realization of the conditions to be met were possible before the original trial on board a vessel.

Why Marine Practice is Conservative

Marine practice is always conservative and it has good reason to be. Naval practice is perhaps somewhat less so because of the need of being strictly up to date in all that pertains to fighting efficiency so that experimentation is more readily accepted. Fighting efficiency is and must always be the primary consideration of the Navy and first cost and operating expense the secondary, except where the latter may directly or indirectly affect the former.

Conservatism in marine practice is more than mere caution induced by past experience with careless designs. No matter how excellent the design of mechanical or electrical equipment may be it is absolutely dependent on the ability of the personnel available for operation and upkeep. The training of personnel on new equipment is an expensive process, and nowhere more so than in the marine and naval service, where efficient personnel is the product of long experience and the number available very limited. Strong prejudice always exists to a more or less extent among such personnel, against innovations, and unless a design has been well thought out originally and the special marine requirements given weight it will be in danger of quick condemnation on the first minor indication of deficiency even though basically the idea may be sound. Particularly is this true of the many small items of auxiliary equipment and apparatus designed to give increased economy, convenience, safety or add in some other way to operating efficiency.

The Case of the Scotch Boiler

As an example of this conservatism the old cylindrical Scotch type boiler still remains the standard in the commercial marine service despite the many attempts to displace it. It has of course certain fundamental characteristics which make it especially valuable for this service such as the large amount of water contained, the volume of the steam space and the relatively smaller amount of attention required in operation and upkeep. But its long record of satisfactory operation and the complete familiarity of the personnel with all the details of the design have much to do with its permanence as a standard in this field. It holds its own in spite of the passing of its companion the reciprocating engine although even the latter has held on longer than was justified by its many un-economical features. This latter was reliable and the personnel were familiar with it which fact, added to the reliability of the design, has made it a favorite until the keenness of competition in ocean freight rates gradually is forcing it out.

It is at once obvious that marine and naval requirements cannot be exactly specified in an absolute sense. However, it seems that it would be of some value to point out certain of the most outstanding features of this service as it differs from conditions on shore.

Manufacturers Too Often Unfamiliar With Seagoing Conditions

The seagoing man often takes for granted a knowledge of conditions existing at sea among landsmen which to the former scarcely seem worth mentioning because they are so obvious. Among manufacturers in general, however, who have not had an opportunity to see for themselves at first hand just what these conditions are it is not believed that they are quite so obvious. Certainly, if their products may be considered as evidence of such knowledge, it is apparent that it is often decidedly lacking or dependence is placed on the failure of marine and naval purchasing agents to discover the defects. The failure of purchasing agents to reject, however, does not prevent a mechanism from failing in service and this soon reacts seriously on the manufacturer and may mean his being more or less completely cut off from the marine or naval market. Among sea going engineers news of failures of material travels swiftly and aided sometimes by competitors' agents it reaches the ears of those far removed from the scene of the original failure and the manufacturer may find himself shut off from supplying materials of entirely different nature than those on which failure occurred and which might be entirely suitable.

It will be understood of course that all the desirable characteristics as to economy, etc., included in a design for land installations are equally important at sea. In addition thereto certain of these must be of a higher standard for sea service and a few included which land service does not require. However, it has been the experience of at least a few manufacturers that, in developing their product to meet marine demands, the same development was quite advantageous and equally applicable in improving their products for land service.

Special Requirements of Commercial Marine Service

The special requirements of commercial marine service are about as follows:

a—Maximum reliability.

b—Minimum space and weight factors.

c—Maximum accessibility for inspection, cleanliness and repair.

d—Maximum resistance to corrosion.

e—Satisfactory operation on a moving platform and in planes inclined to the horizontal from 15 to 20 degrees with special attention to lubrication under these conditions which occur on a ship in service.

f—Ability to withstand large and uneven stresses induced by the laboring of a vessel in a heavy sea way and the variable propeller load.

*Laboratory officer, New York Navy Yard, Brooklyn, N. Y.

g—Satisfactory operation under vibrations of the mounting at fairly high frequencies.

h—Adequate spare parts but no more than is actually necessary, exactly fitted to their place and arranged for easy installation and stowage.

j—Suitable marking of all equipment and parts for ease of identification and accurate requisitioning from distant parts of the world.

The special requirements for the naval service include all of the above with a somewhat higher standard of performance especially in regard to the first four. In addition it demands the following characteristic:

a—Satisfactory and continuous performance under heavy shock, as that induced by the discharge of the vessel's own guns of fairly well known and constant amount, or by the striking of enemy's shells and explosion of mines or torpedoes at almost any point of the ship's structure and of more or less unknown amount. The design must always take into account the maximum possible effect.

Another point of difference between the marine and naval services is that the latter usually is supplied with sufficient personnel for inspection, upkeep and repair—a personnel better organized and under better control. Thus material on naval vessels receives more attention and care and can be kept in better condition than that of the merchant marine. However, on a naval vessel there is a much greater quantity of apparatus and equipment of a more delicate nature so that in spite of the additional personnel available the design must take into account and consider all of the factors set forth.

Reliability

Taking up individually the above enumerated requirements for discussion it appears that reliability is the most important and essential of all. Many of the others that follow in the enumeration more or less directly affect this fundamental characteristic. Reliability of course is important in land practice but to a relatively much less degree. Failure in a land plant rarely causes more than inconvenience and some financial loss. Nearly always spare machines are available or an auxiliary power source can be utilized with little difficulty. Further, unlimited technical assistance and repair facilities are quite usually at hand or can be quickly obtained. First cost only limits the number of spares that can be kept on hand and often nothing of consequence is strictly essential because of the proximity to the source of supply.

In contrast to this consider the position of a vessel at sea when break down occurs. If it takes place in stress of weather, as is often the case, the conditions are infinitely worse. Anyone who has ever attempted important repairs on a ship which is rolling and pitching violently in a heavy seaway will not be very approachable on the subject of the purchase for a vessel of an apparatus whose reliability is not absolutely proven. At such a time too the name of a manufacturer who has thoughtfully anticipated such conditions and planned for ready lifting and handling and easy installation of spares will be blessed. Particularly is this true when spares fit properly without the slightest alteration.

Repairs at Sea

The number of spares that can be carried is very limited. A vessel is built to carry cargo—not a multitude of spares—and in the case of a naval vessel to make high speed for fighting and all unnecessary weight must be cut down. To make the necessary repairs a vessel can draw only upon her own resources and the ship's engineers must furnish all the technical assistance that is needed. The lives of the crew and passengers and the value of the ship and cargo may be and often are dependent upon their unaided skill. The facilities available are never more than a meager supply of machine and hand tools, the knowledge of the ship's engineers and the skill of their own hands.

As a rule there is always sufficient floor space available in land installations or it can easily be obtained, while weight is seldom if ever an installation factor, other than a problem of handling. On ship board, however, there is never entirely adequate space. In order not to defeat the object for which the ship is built it becomes one of the greatest problems of marine construction to arrange her necessary equipment in the smallest possible space, consistent with safe operation. The same is true of weight. The capacity and floatability of a vessel are the factors which justify her existence as a ship and anything that detracts from either the one or the other reduces in the same proportion her value for the purpose for which she was constructed.

Accessibility

Considering the necessarily restricted space it is at once obvious why special attention must be given to accessibility. When cleaning and repairs must be executed in an extremely confined space, a design with conveniently accessible units will necessarily be considered the most successful. The troubles of the operating engineer at sea are sufficiently great under the handicap of confined working space without adding to them by the installation of a poorly thought out assembly which would be difficult to take care of even under normal conditions of illumination, floor space and handling facilities. The personnel on board ship usually does its work in cramped locations, with poor lighting and high temperature conditions and on an often violently moving platform. Careful thought must be given to any heavy weights that must be handled and facilities provided for taking care of them under rolling and pitching conditions on a vessel. To lose control of a heavy weight under the latter condition endangers life and limb and even possibly the ship itself. Easy inspection is also essential in order to promote reliability. Any apparatus, the careful inspection of which is difficult, will naturally receive less attention and break downs of serious nature, which might be prevented by timely steps to repair worn parts, will occur.

Corrosion

Sea air is highly corrosive and parts not properly protected or of easily corrodible material will disintegrate with the greatest rapidity, far exceeding that of any ordinary land practice. Even in fittings designed to be strictly watertight, the structure "breathes" during changes of temperature and air saturated with moisture will enter and corrodible materails will be quickly attacked. Increase of temperature forces air out and a drop will draw air in. A further drop will precipitate moisture from the saturated sea air and corrosion commences. Below decks there is leakage from pipes and condensation of vapor of steam and oil added to sea air from the ventilating blowers and usually high temperature—in general, about the best conditions to promote active corrosion possible to obtain. To this may be added the ever present danger of galvanic action between the many dissimilar metals of a ship's structure and water with varying degrees of acidity or alkalinity. It is not possible for a design to go too far in an effort to resist corrosion. It is the ever present foe of steel ships and their fittings and the landsman designing for marine installations must appreciate the danger to the full or his design must inevitably fail.

Marine machinery operates on a moving platform. Any apparatus that employs the force of gravity to function properly will be at a serious disadvantage in the marine field even if it would work at all, as this force will be received through constantly changing angles. One of the most common difficulties experienced is interference with the lubrication through the changing of the amount of the bearing pressures and the introduction of stresses and strains through the working of the flexible ship's structure which forces change of alinement of bearings and varies the bearing clearances.

FLEXIBILITY OF SHIP'S STRUCTURE AND VIBRATION

Further, due to this flexibility of the ship's structure, stresses are uneven and the design must have a rigidity and strength to withstand them, entirely uncalled for in land practice. The laboring of a ship in a sea way, the variable propeller load and differences in the loading all contribute toward making even the lightest duty relatively difficult under such varying conditions. The tunnel bearings of the propeller line shafting of a vessel give a good illustration of this as the temperature of these bearings is constantly changing as the loading or the weather conditions change. A bearing running cold today will be hot and require constant attention the following day if the loading is changed or the weather conditions vary.

Vibrations are more or less a source of difficulty. However, in this respect conditions on land are often nearly as bad. In every part of the ship's structure, however, they are present. With modern vessels they are less a problem. They affect instruments mainly and the more delicate of the ship's equipment and in such classes of apparatus they must always be considered.

SPARE PARTS

The question of spare parts has been discussed under the requirement of reliability. The number must be limited not only because of cost but because of lack of stowage space. Those that are furnished must be accurately fitted, arranged for stowage, handling and ease of installation. A modern naval vessel particularly is a veritable maze of intricate machinery for each item of which more or less spare parts must be carried. Convenient stowage is difficult and parts must be properly protected and arranged for easy identification, particularly for naval vessels. Interchangeability is a great advantage not only for parts carried but for parts that may be ordered in distant parts of the world. Proper arrangements for identification of parts in ordering must be arranged for in order to avoid confusion and delay when the need may be urgent and the factory distant.

The Navy, as previously stated, adds to the above the requirement that the apparatus shall be proof against shock. It is readily appreciated that, in a naval engagement, shock of discharge of a vessel's own guns and the impact of the enemy's shells, torpedoes and mines on the vessel's structure may seriously derange vital mechanisms even though no direct hit on the mechanism itself were made. The effect of discharge of a vessel's own guns is a measurable quantity, but the effect of the striking of enemy' shells, etc., is a very uncertain affair. However, these things must be always taken into account in a design and allowed for in the mounting and in the relations of the various parts to each other. Such equipment as circuit breakers, for example, form a good illustration of equipment easily deranged by shock. It would appear at first thought that this demand could not always be satisfactorily met but it must be met, if a naval vessel is to fulfill its mission as an efficient fighting unit, and experience has shown that by careful consideration much can be accomplished as in the case of the illustration given above, viz. naval circuit breakers.

Much more could be said along these same lines but it is hoped that enough has been given to bring out some of the most important of the difficulties to be overcome in successful marine design as opposed to land practice.

Chamber of Shipping Gives Rules to Prevent Pilferage

Claims Twenty Times as Large as Before War Have Been Paid for Pilferage by Shipowners Since Armistice

THE Council of the British Chamber of Shipping appointed a committee in 1920 to study the subject of pilferage and to prepare a set of recommendations for the prevention of theft which has increased to an alarming extent since the war. This committee has formulated rules which it is hoped will be found applicable to the ports of all nations, and particularly to those ports where shipowners are suffering from excessive claims on cargo.

Three reasons are given for the increase of the pilferage evil, namely: (1) The general increase in values which augmented the pre-war claims about threefold. (2) Chaotic conditions occasioned by the war, especially interference in and control of trading facilities by Government departments and the congestion resulting from a trade boom immediately succeeding the war. (3) By far the most important factor, however, was the increase in the general debasement of the standard of common honesty which was a legacy of the war.

While the following rules are necessarily general in character in order that they may cover all ports and while some ports have organizations which are effective in the prevention of pilferage, it is recommended that the rules be accepted by shipowners, particularly where pilferage is common.

1. TALLIES AND WATCHING

"Tallies should be taken both in and out of ship. It is specially important that this should be done when discharging on to open quays, or into lighters, or on to the quays of docks and warehouses not under control of the shipowner.

"The absence of tallies should be permissible only when the quay is absolutely under the sole control of the shipowner; but even where shipping companies use their own wharves the Committee consider it is desirable that these tallies should be taken in order to locate the individual responsibility of each man handling the goods. Without such precaution it is impossible to investigate satisfactorily each stage in the process of discharge and loading and thus fix the exact spot where the error, loss or damage arose.

"Generally, the Committee desire to emphasize that it is impossible for officers to perform their duties adequately unless a legible and clear tally of the cargo is received at the port of shipment More care is required on the part of all tally clerks to ensure that their tallies, including carbon copies, are complete and distinct. If these particulars are not accurate and distinct, it leads to much confusion on discharge and in such cases the officers who supervise the disharging are seriously hampered in their duties.

2. OFFICERS

"An officer or his representative should be appointed to each hold.

"Where sufficient officers are not available to supervise at each hold, substitutes should be appointed from among the petty officers, apprentices, wireless operators and other reliable members of the crew.

"Wireless operators and watchers should be regularly employed in addition to officers in connection with the work of supervising the tallying and watching of cargo, and it is desirable that steps should now be taken to constitute them part of the ship's personnel for performing cargo duties in port, under the orders of the master. This is a reform which will yield the wireless operators some much-needed occupation in port, and the deck officers some relief at busy times.

3. ALPHABETICAL TALLY BOOKS

"The Committee recommend the extended use of the aphabetical system (with which most shipowning organizations are familiar) by those tallying on behalf of ship, which prevents collusion with those using continuous sheets tallying against the ship. If the tally into the ship is not taken alphabetically, the continuous sheets should show the number of the hatch into which cargo is being worked. The officers during the voyage should prepare from these

loading sheets a separate alphabetical tally book for the cargo for each port of destination in each hatch and, in addition, a second set of such alphabetical books may be prepared for use by ship's tally clerks in discharging. This will be found most advantageous. This second set should show the marks only, and the numbers should be added by the ship's tally clerk in discharging. On ceasing work each day these tally clerks should hand their books or tally sheets to the officers to check them off with their own complete tally books and thereby be able to follow closely the accurate outturn and take prompt steps to trace any deficiencies and to have 'bad order' goods assessed for damage by ship's surveyor before leaving port. The books with marks prepared save many errors through speed of discharge leading to inaccurate record of marks.

4. Precautionary Measures on Board Ship

"(a) There should be only one entrance to cargo holds, viz., down the hatchway.

"(b) All ventilators should be protected in order to prevent access to holds through them.

"(c) All hatches should be fitted with bars and locks capable of being quickly and easily manipulated and kept closed and locked during the passage between coastal ports.

"(d) In insulated steamers when holds are loaded with general cargo the doors leading from the engine room, &c., to the air trunks and holds should be locked and the key kept always by a responsible cargo officer.

"(e) During meal hours, the deck should never be left without an officer in charge, and when contractors are working in the holds during the stevedores' meal hours a special watchman should be stationed in the hold to watch these men.

5. Pilferage at Sea

"If, during the course of a voyage, tampering with the cargo or pilferage thereof has been discovered by the officers, the Commitee recommend the master of the ship to communicate with the agents by wireless requesting them to send detectives on board the ship before the vessel is moored alongside the quay; so that a proper search may be instituted and the thieves discovered and prosecuted.

6. Dock and Harbor Aurhorities and Ships' Passes

"Where goods are tallied by the ship within sight of the ship's rail, dock and harbor authorities receiving the cargo should always give receipts for same.

"The authorities should be more strict in the scrutiny of persons allowed to enter and leave dock and harbor premises.

"A system of triplicate passes should be adopted in all ports for any goods taken out of docks under the ship's pass (called 'Goods Passes'), one to be retained in the pass book of ship, and two to be handed to the person in charge of the goods, both of which should be given up at the dock gates. The dock authority should retain one of these two for their purposes and send the other to the ship's agent. Where this procedure has been adopted it has been of great benefit.

"There should be stricter examination of conveyances by road and water (carts, lighters, &c.) by those who are charged with this duty.

"The Committee recommend that port authorities should accept full responsibility for all cargo not removed from transit sheds within seventy-two hours from final landing of the goods. The Committee consider similar conditions should even apply at ports of the world where the legal limit of seventy-two hours is not imposed, particularly where, as is frequently the case, the port authority is the constituted agent of the consignee for taking delivery. This practice should be recognized in cases where steamship owners rent a quay with sheds for the discharge of their steamers' cargoes. It is obvious where sheds are rented merely as transit sheds the receiving authority should be responsible for the safe-keeping of the goods in such sheds, after the usual seventy-two hours.

7. Damaged Packages

"When, during the discharge, packages are discovered which have been tampered with, or damaged in any way, the Committee recommend the following system should be adopted:

"(1) Such packages should be retained on board the ship under the officers' supervision until they can be discharged and their condition certified, or

"(2) Immediately on landing placed in a special cage, lock-up or other safe depository.

"(3) As a precautionary measure such packages should immediately be weighed and the ascertained weight indelibly marked on the package; they should also be securely fastened.

"(4) Goods of this description should be thoroughly examined and the condition of them agreed with the officers before the ship leaves the port.

"Customs authorities should be urged to support officers and agents in this procedure.

8. Pilferage Reports to Owners

"Shipowners should bring claims at all ports under the scrutiny of a well-equipped department at head office. The results are calculated well to repay the expenditure. Reports should be sent direct to such claims department promptly at the time when the pilferage is discovered, and should show specifically which claims arise from pilferage. These reports should contain precise particulars to enable the department to trace the goods in question.

9. Legal and Magisterial Action

"Shipowners should prosecute every detected case of pilferage. There is a certain reluctance to institute legal proceedings, but such proceedings are imperative if pilferage is to be stopped.

"Magistrates should be urged to impose imprisonment on persons convicted of pilfering. Fines are generally inadequate and moreover are usually paid by the delinquents' mates or associates.

"The magistrates' powers of dealing with persons convicted of unlawful possession should be enlarged and the maximum fine in this country should be increased from £5 to £20.

10. Bills of Lading, Mate's Receipts and Indemnities

"The Committee strongly deprecate the custom of issuing Bills of Lading for goods 'Received for Shipment' except where the circumstances make no other form appropriate; such a system gives scope for pilferage. In no case should shipowners, however great the pressure from merchants, issue a 'Shipped' Bill of Lading until the goods are actually on board the steamer, as the difficulties of protecting the steamer against claims for pilferage which may have happened before shipment are thereby greatly increased.

"Mate's receipts should not be claused indiscriminately with words used as 'more or less frail.' The actual condition of the goods should at all times be accurately noted in detail on the receipt and also on the Bill of Lading. Many shippers desire shipowners to accept indemnities in lieu of clausing Bills of Lading in accordance with the facts; this practice should be discouraged to the utmost. Courts of Law condemn the practice of giving such indemnities, by which bankers and other holders of Bills of Lading are undoubtedly misled.

11. Insufficient or Frail Packages

"Shipowners should reserve their right to reject goods appearing to be insufficiently packed and also their right to plead insufficiency of packing, at whatever part of the voyage it comes to light.

12. Special Goods, Specially Addressed Packages and Returned Packages

"These goods should always be carried in lock-ups securely fastened with two locks. The master should retain the key of one lock and the principal cargo officer the other. The cage or chamber should never be opened unless an officer is present.

13. Customs Examination

"Customs officials should mark with an official stamp or seal all cases and casks from which samples have been extracted.

14. Instructions to Masters and Officers

"The Committee suggest that shipowners should revise their standing instructions to masters and officers in reference to the care and handling of cargo with the object of bringing them up to date and giving this aspect of their officers' duty its due prominence.

"It has been said that the Committee's proposals are not likely to secure the active co-operation of the ship's officers. In reply to this evidence is forthcoming to show that officers are realizing their duties and are giving the most loyal assistance wherever the proposals are being adopted. In some cases further improvements in practice are suggested by the officers, which shows not only that the right lines are being recommended, but that the interest of officers has been aroused. The Committee suggest that Liner Cargo Superintendents should be requested to encourage the officers to take an interest in cargo as being the connecting link between the cargo departments at the respective ports.

15. Department of Overseas Trade

"Finally, the Committee desire to bring to the notice of shipowners this Department which is responsible to the Foreign Office and the Board of Trade for commercial matters in the hands of British Government representatives abroad. Each British Ambassador and Minister has on his staff a Commercial Secretary who is responsible for co-ordinating the work of the Consuls. Some of the Commercial Secretaries during their leave in this country have visited the Chamber of Shipping, and the Committee had the privilege of meeting them. They appear to have been excellently chosen for their combined knowledge of British commercial matters and the conditions of the country to which they are accredited. In the Committee's view, shipowners would be well advised to keep in touch with these gentlemen.

British Regulations Against the Discharge of Oil Into Navigable Waters*

OIL in Navigable Waters Act, 1922. Chapter 39. An Act to make provision against the discharge or escape of oil into navigable waters. (4th August 1922).

Be it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

Penalty for Discharge of Oil in Navigable Waters

1.—(1) If any oil is discharged, or allowed to escape whether directly or indirectly, into any waters to which this Act applies from any vessel or from any place on land or from any apparatus used for the purpose of transferring oil from or to any vessel to or from any other vessel (whether a vessel to which this Act applies or not) or to or from any place, the owner or master of the vessel, from which the oil is discharged or allowed to escape, the occupier of the land, or the person having charge of the apparatus, as the case may be, shall be guilty of an offence and shall, in respect of each such offence, be liable on summary conviction to a fine not exceeding one hundred pounds:

Provided that it shall be a good defence to proceedings for an offence under this section to prove—

(a) if the proceedings are against the owner or master of a vessel, that the escape of the oil was due to, or that it was necessary to discharge the oil by reason of, the vessel being in collision or the happening to the vessel of some damage or accident, and also, if the proceedings are in respect of an escape of oil, that all reasonable means were taken by the master to prevent the escape; and

(b) if the proceedings are against any other person and are in respect of an escape of oil, that all reasonable means were taken by that person to prevent the escape.

(2) It shall be lawful for a harbour authority to appoint a place within their jurisdiction at which the ballast water of vessels in which a cargo of petroleum spirit has been carried may be discharged, and where a place is so appointed any such ballast water may, notwithstanding anything in this section, be discharged at that place, but only at such times and subject to such conditions as the harbour authority may from time to time determine:

Provided that the foregoing provision shall not apply to ballast water containing oil other than petroleum spirit.

For the purposes of this subsection, the expression "petroleum spirit" means refined petroleum which is subject to rapid evaporation and which, when tested in the manner prescribed by the Petroleum Act, 1879, or any enactment amending that Act, gives off an inflammable vapour at a temperature of less than 73 degrees of Fahrenheit's thermometer.

Prohibition of Transfer of Oil at Night

2.—(1) It shall not be lawful during the hours between sunset and sunrise to transfer any oil to or from any vessel lying in any harbour unless notice of intention so to do has been given in accordance with the provisions of this section.

(2) If any oil is transferred to or from any vessel in contravention of the provisions of this section, the master of the vessel and, if the oil is transferred from or to premises on land, the occupier of the premises shall, in respect of each offence, be liable on summary conviction to a fine not exceeding twenty pounds.

(3) A notice for the purpose of this section must be given to the harbour master of the harbour in which the vessel is lying and shall be of no effect unless given at least three hours and not more than ninety-six hours before the time at which the operation of transferring the oil commences:

Provided that, in the case of an operation to be performed at a place where such operations are frequently and regularly carried on, or in the case of a transfer of oil for fire brigade purposes, the notice may, instead of being a notice given to the harbour master within the time hereinbefore provided, be a general notice given to the harbour master to the effect that such operations will during such a period not exceeding twelve months from the date of notice, as may be specified therein, be carried on between sunset and sunrise.

Keeping of Records with Respect to Transfer of Oil

3.—(1) There shall be kept in the case of every vessel a record, in such form as the Board of Trade may prescribe, of all operations in connection with the transfer of oil to and from the vessel.

(2) The record required to be kept under this section shall, in the case of a barge, be kept, so far as relates to the transfer of oil to the barge, by the person supplying the oil, and, so far as relates to the transfer of oil from the barge by the person to whom the oil is delivered, and shall, in every other case, be kept by the master of the vessel.

(3) Every record kept under this section may at all reasonable times be inspected by the harbour master of the harbour in which the vessel is or, in the case of a barge, was at the time of transfer or by any person duly authorised in that behalf by the Board of Trade, the Minister of Agriculture and Fisheries, the Fishery Board for Scotland, or the Ministry of Commerce for Northern Ireland.

(4) If any person required to keep a record under this section fails to keep such a record or to make proper entries therein, or to produce the record on a demand in that behalf made by any person authorised to inspect it, he shall, in respect of each offence, be liable on summary conviction to a fine not exceeding fifty pounds, and if any such person makes any entry in the record which is to his knowledge false or in any material particular misleading, or wilfully fails to make any entry in the record, he shall, in respect of each offence, be liable on summary conviction to a fine not exceeding one hundred pounds.

Liquid Contained in Spaces Used for Carriage

4.—(1) Where oil has been contained in any tanks or other spaces in a vessel, any liquid discharged or allowed to escape from those tanks or spaces shall, unless it is proved that the tanks or spaces have been cleaned of oil, or that the liquid has been freed from oil by means of a separating apparatus, be deemed to be oil within the meaning of this Act.

(2) In the case of proceedings against any person other than the master of a vessel, evidence of the matters aforesaid may be given by means of a certificate signed by the master, and, if the master of a vessel gives any certificate under this section which is to his knowledge false or in any material particular misleading, he shall, on summary conviction, be liable in respect of each offence to a fine not exceeding fifty pounds.

(3) In this section the expression "master of a vessel" means the person named as the master in the agreement with the crew.

*From the Transportation Division, Department of Commerce, Washington, D. C.

Application of Fines

5.—Where any person is convicted of the offence of having in contravention of the provisions of this Act discharged or allowed to escape any oil into any waters to which this Act applies, the court before which he is convicted may, on application of the prosecutor, order that the whole or any part of the fine imposed in respect of the offence shall be paid to such person as the court may direct for the purpose of being applied by him in or towards meeting any expenses incurred or to be incurred in the removal of the oil so discharged or allowed to escape.

Power to Inspect Premises and Vessels

6.—(1) The Board of Trade may, if they think fit, either at their own instance or at the instance of the Minister of Agriculture and Fisheries, the Fishery Board for Scotland, or the Ministry of Commerce for Northern Ireland, or of any local authority, appoint any officer of the Board of Trade or any other competent and independent person to inspect any vessel being in any waters to which this Act applies, and any person so appointed or the harbour master of the harbour in which the vessel is may at all reasonable times enter upon the vessel and examine the measures adopted to prevent the escape of oil.

(2) If it is represented to the Board of Trade, by the Minister of Agriculture and Fisheries, the Fishery Board of Scotland, or the Ministry of Commerce for Northern Ireland, or by any local or harbour authority, that there is reason to suspect that oil is escaping or has escaped, whether directly or indirectly, into waters to which this Act applies from premises adjacent to or in the neighbourhood of those waters, the Board of Trade may, if they think fit, appoint any officer of the Board or other competent and independent person to inspect the premises, and any officer or person so appointed may at all reasonable times enter upon and inspect the premises.

(3) If any person obstructs or interferes with any person authorised to enter on any premises or vessels under this section, he shall, on summary conviction, be liable in respect of each offence to a fine not exceeding ten pounds.

Legal Proceedings

7.—(1) Where an offence under this Act is alleged to have been committed by the master of a vessel who thereafter departs from Great Britain and Northern Ireland before the expiration of the period within which proceedings for the offence might have been instituted against him, proceedings for the offence may, notwithstanding any thing in the Summary Jurisdiction Acts, be instituted against him at any time within two months next after the date on which he first returns to Great Britain or Northern Ireland.

(2) For the purpose of any proceedings for an offence under this Act, the offence may be treated as having been committed either at the place at which it was actually committed or at any place in which the person charged with the offence may at any time be.

(3) Where a fine imposed by any court in proceedings against the owner or master of a vessel for an offence under this Act is not paid at the time and in manner ordered by the court, the court shall, without prejudice to any other powers of the court for enforcing payment, have power to direct the amount remaining unpaid to be levied by distress or poinding and sale of the vessel, her tackle, furniture and apparel.

(4) Proceedings for an offence under this Act shall not be instituted in the case of an offence committed in or in relation to the waters of a harbour except by the harbour authority, and in any other case except by a person authorised in that behalf by special or general directions of the Board of Trade, the Minister of Agriculture and Fisheries, or the Ministry of Commerce for Northern Ireland: Provided that nothing in this subsection shall apply to the institution of proceedings in Scotland.

Interpretation and Application

8.—(1) In this Act, unless the context otherwise requires—

The expression "oil" means oil of any description, and includes spirit produced from oil and oil mixed with water:

The expression "harbour" means any harbour whether natural or artificial, and includes any port, dock, estuary or arm of the sea, any river or canal navigable by sea-going vessels, and any waters in which sea-going vessels can obtain shelter or ship or unship goods or passengers:

The expression "harbour authority" includes all persons or bodies of persons, corporate or unincorporate, being proprietors of or entrusted with the duty or invested with the power of constructing, improving, managing, regulating or maintaining a harbour:

The expression "harbour master" includes any person appointed by a harbour authority for the purpose of enforcing the provisions of this Act:

The expression "master" when used in relation to any vessel means the person having the command or charge of the vessel for the time being:

The expression "vessel" has the same meaning as in the Merchant Shipping Act, 1894:

The expression "barge" includes lighter or like vessel:

The expression "transfer" in relation to oil means transfer in bulk:

The expression "local authority" means, in the application of this Act to England, the council of a county or county borough or urban or rural district or a port sanitary authority, in the application of this Act to Scotland the council of a county or burgh or a port local authority, and, in the application of this Act to Northern Ireland, the council of a county, county borough or county district, or a port sanitary authority.

(2) This Act shall apply to any vessel which is capable of carrying in bulk, whether for cargo or for bunker purposes, more than twenty-five tons of oil, or which, though not so capable is constructed or fitted to carry in bulk as aforesaid more than five tons of oil in any one space or container.

(3) The waters to which this Act applies are the territorial waters of Great Britain and Northern Ireland and the waters of harbours therein.

(4) For the purposes of section six of the Government of Ireland Act, 1920, this Act in its application to Northern Ireland shall be deemed to be an Act passed before the appointed day.

Short Title and Saving

9.—(1) This Act may be cited as the Oil in Navigable Waters Act, 1922.

(2) The provisions of this Act shall be in addition to and not in derogation of or substitution for any provisions for the protection of a harbour as defined in this Act contained in any existing Act or re-enactment thereof or in any order, rule, regulation, or bye-law made or to be made under such Act or any re-enactment thereof.

(3) This Act shall come into operation on the first day of January, nineteen hundred and twenty-three.

New York Electrically Driven Municipal Ferryboats

Propulsion by Squirrel Cage, Induction Motors Supplied With Current by Turbine-Driven Alternating Current Generators

By A. Kennedy, Jr.*

ELECTRIC ship propulsion which was fostered and largely developed through the effort of the General Electric Company has recently entered a new field of application, that is, the propelling of large double-ended ferryboats by means of turbine electric alternating current drive.

Few people, apparently, realized until recently the great advantage to be gained by propelling double-ended ferryboats electrically. For years it has been known that the ordinary bow propeller on double-ended ferryboats was extremely inefficient, but comparatively little has been done to improve the over-all efficiency of such boats.

Special propellers have been designed and built and they have, in certain cases, shown a material saving over the ordinary types of propellers used, but it was not until electric drive was applied to boats of this type that full advantage was taken of conditions known for years to exist in regard to propulsion of double-ended ferryboats.

Propelling Machinery

The three New York ferryboats being built by the Staten Island Shipbuilding Company will each be propelled by an 8-stage condensing Curtis marine type turbine, which has proven particularly well adapted for marine service. This fact is substantiated by the records of the Emergency Fleet Corporation, and also by the fact that approximately 90 percent of the turbine driven ships being built at the present time in England, which is the home of the Parson type turbine, are using the Curtis type of turbine.

Each ferryboat will be equipped with one General Electric turbine-driven alternating current generator, and this generator will in turn drive two marine type 2-speed induction motors having double squirrel cage rotors. In this connection, it is of interest to note that the induction motor rotors being used on the new New York City ferryboats are similar in design to those of the *New Mexico,* which was the first electrically driven battleship.

The relative speeds of the bow and stern propellers were determined by tank tests conducted for the City of New York, under the direction of M. G. Kindlund, naval architect.

The high speed winding will deliver 2,100 shaft horsepower at 176 revolutions per minute and the low speed will deliver 100 shaft horsepower at approximately 122 revolutions per minute.

The apparatus for controlling the motors and generator are of the dead front cell construction type. The general arrangement of the control panel is in brief as follows:

Control Panel

The bottom section includes a master control switch, watt-hour meter, generator rheostat handle, one electrical control lever, one turbine speed control switch and three manually operated levers. The electrical control lever controls the operation of the solenoid operated contactors. The turbine speed control switch controls the speed of the turbine from the control panel. The manual levers arranged from right to left are—the turbine throttle lever and two levers which are used in case of special emergency for operating the contactors.

The next section includes the various instruments and the top section the contactors.

After the turbine has been started and the hand operated throttle valve thrown wide open, the desired speed of approximately 25 percent of normal speed may be obtained by means of the turbine speed control switch which operates a long range governor. This governor may be operated, if desired, manually, by means of a hand wheel located on the turbine, or the speed controlled by the hand operated throttle valve lever located on the control panel.

Operation of the Electrical Lever

The operation of the electrical lever is as follows:

The first position in either direction will close the line contactors on the stern high speed motor winding. The second position will close the generator field contactors applying approximately double excitation. It should, therefore, be noted that the main line contactors for high speed propelling motor windings are closed on the dead circuits. The propelling motor having started and come in step with the generator, the electric lever will then be moved to the third position which reduces the excitation on the generator to normal. This is done by means of a transfer resistance so that generator field circuit is not opened during this transfer. The ship may then be brought up to the desired speed.

The fourth position of the electrical lever closes the bow slow speed motor contactors, this being the maximum efficiency running position. The slow speed motor winding is so designed that when this motor is operating on this winding it cannot take more than approximately 200 percent current and may, therefore, be easily thrown on the line with full voltage. The water acting on the bow propeller will tend to break the bow propeller loose and, therefore, this motor is not designed for the normal breaking away torque which would be required in case this motor was thrown on the line before the ship was under way.

To stop the ship, the electrical lever is thrown to the off position, there being a certain time interval between the opening of the generator field contactors and the opening of the main propelling motor contactors. This time interval is provided so that the generator field will die down and, therefore, there will be a minimum amount of arcing on the main propelling motor high speed winding contactors. At the same time that the electrical lever is thrown to the off position, the turbine speed will be reduced by means of the electric speed switch. The governor on the turbine is so designed that it will hold constant speed from 25 percent to 100 percent either with or without load.

Maneuvering

The ship may be maneuvered, as described above, either ahead or astern.

In maneuvering, all power is placed on the most efficient propeller for accomplishing the desired result; that is, in stopping the boat, all power will be placed on the bow high speed motor winding, the speed of the motor being controlled by the speed of the turbine.

To further increase the efficiency of these ferryboats, most of the engine room auxiliaries are motor driven, obtaining their power from a 125-kilowatt condensing turbine driven direct current generator.

*Marine Engineering Department, General Electric Company, Schenectady, N. Y.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Allowances for Scrap in Ship Construction

Q. (1172).—What do you consider reasonable allowances for scrap in the cases of some of the principal materials entering into ship construction?

A. (1172).—The following percentages may be taken as reasonable, although there is some variation due to differences in practice in different building yards:

	Scrap—Percent
Plates and shapes	15
Rivets	15
Steel and iron castings	10
Steel forgings	10
Iron forgings	15
Brass castings	10
Bronze	10
Zinc	10
Lead and copper	net
Rubber	10
Decking (white or yellow pine)	10
Tarred felt	net

Resistance Due to Foul Bottom

Q. (1173).—Can you give me any information as to the relation between time out of dock and resistance due to foul bottom?

A. (1173).—Only very general information can be given in answer to your question because the result in a given case depends upon the temperature and the degree of salinity of the water, the speed of the ship through the water when under way, and the proportion of the time out of dock which has been spent in actual steaming.

Admiral Taylor in "Speed and Power of Ships" states that in extreme cases of fouling a vessel's bottom may have a complete incrustation of shell fish and this may result in skin resistance four or five times that of the clean ship. He states further that, in practice, such fouling is permitted only under exceptional circumstances, vessels being docked at intervals. But even in cool waters when fouling usually goes on rather slowly a vessel three or four months out of dock is liable to have an increase of 20 percent or more in skin resistance, and in tropical waters the increase of resistance is greater.

In a certain case with which the writer is familiar a vessel divided her time about equally between cool and warm waters. She spent a short time in fresh but most of her time in salt water. She spent about twenty percent of the entire time in actual steaming at slow speeds. During her first six weeks out of dock her resistance increased about fifteen percent. Thereafter for about seven months the increase was gradual and quite uniform. At the end of the period of nine months out of dock the resistance had increased 30 to 40 percent over that on leaving dock.

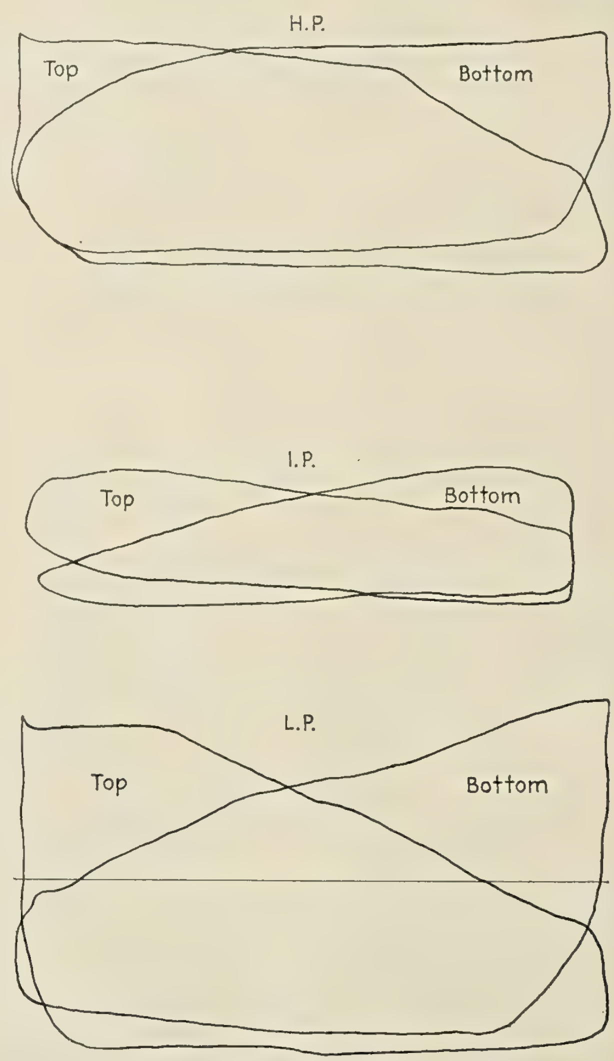
Valve Gear Setting

Q. (1170.)—What does the enclosed set of indicator cards indicate as to the valve gear setting and how should the valves be corrected? The engine cylinders are 27 inches, 44½ inches and 73 inches in diameter by 54 inches stroke. The steam pressure is 190 pounds per square inch.

A. (1170).—The comments which follow may be in error because of insufficient information and the faintness of the high pressure card. Certain assumptions had to be made, therefore, it does not seem safe to suggest changes either in the valve setting or to the valves.

High Pressure Cylinder.—Bottom release late as is also the bottom cut off.

Intermediate Pressure Cylinder.—Top card shows excessive compression and late admission. Bottom card shows late compression and early admission. The peculiar shape of the top right corner may be due to a leaky high pressure valve or a small receiver from the high pressure to the intermediate pressure steam chest, and the late high pressure



Set of Indicator Cards from Triple Expansion Engine

bottom release, steam coming to the intermediate pressure valve but little faster than it is being used, thus causing the horizontal steam line. Then the high pressure exhaust port begins to uncover more rapidly than the intermediate pressure steam port opens and pressure is built up in the receiver causing the steam line to rise.

Low Pressure Cylinder.—Both top and bottom cards show early compression and the bottom card late admission and release. The top card as a whole is not bad.

In order to study this problem for recommendations with any degree of assurance it would be necessary to know the order of the cranks and the side on which steam is taken for each valve, also the valve diagrams, if available.

Non-Shatterable Glass Introduced in the Marine Field

A NON-SHATTERABLE glass, manufactured by the Indestructo Lens and Windshield Company, Brooklyn, N. Y., which has found wide application in commercial service of various kinds, has been adapted to marine service. This glass is specially used for port lights where it is necessary to protect the ship against water damage. Wherever ordinary glass can be broken by wave action or other causes this indestructible glass may be utilized to advantage.

"Indestructo" glass is of laminated construction consisting of alternate layers of glass and pyralin welded into a solid homogeneous mass under pressure and intense heat. Vision is in no way impaired by the process and it is stated by the company that when the glass has been cracked through accident its structural strength is not materially decreased but can be continued in service indefinitely and afford protection against water damage. In tests conducted for Navy service the glass has been subjected to pressures up to 500 pounds per square inch without destroying the glass beyond usefulness. On naval vessels this glass is used almost exclusively; in merchant service it has been used for binnacle covers, gage glasses, battery boxes, glass doors and door windows, port lights, etc.

In reconditioning the *Leviathan* this glass is being used to replace the lights in 525 ports. "Indestructo" glass is being distributed by the Protective Appliance Company, 232 Vanderbilt avenue, Brooklyn, N. Y.

NEW BOOKS

The Welding Encyclopedia, Second Edition. Edited by L. B. Mackenzie and H. S. Card. A reference book on the theory, practice and application of the four autogenous welding processes. Size, 6 by 9 inches. Pages, 388. Illustrations, 550. Chicago, Ill., 1922: The Welding Engineer Publishing Company.

The first half of this book consists of a dictionary of all words, terms and trade names used in the welding industry. Included in this arrangement are instructions for welding operations on the most common types of repair work and production work, descriptions of the modern methods of testing welds, specifications for welding rods and wires for all classes of work, and descriptions of the application of welding to the various industries, such as automobile repairing, refrigerating machinery, structural steel, etc. Following the dictionary section are separate chapters on oxy-acetylene welding, electric arc welding, electric resistance welding and thermit welding. Complete descriptions of each one of these processes are given, followed by general operating instructions and special instructions for the application of each process to every metal which can be welded by it. Separate chapters are included on the subjects of boiler welding, tank welding, pipe welding and rail joint welding. Another section is devoted to the rules and regulations enforced by Federal and State authorities and insurance companies on the construction, installation and operation of welding equipment and on their application to various structures. A special chapter deals with the heat treatment of steel, one of the most important metals which the welder handles. A collection of charts and tables shows the variety of methods of preparing joints for welding, gives information on the characteristics of all the commoner metals, shows how to tell the temperature of metals by a color chart, and also shows a color chart explaining the proper adjustment of the oxy-acetylene flame. The catalogue section at the end of the book describes and illustrates the standard lines of welding equipment and apparatus.

Practical Guide for Diesel Engine Operators

Reviewed by A. J. C. Robertson*

Notes and Sketches on Marine Diesel Oil Engines. By J. W. M. Sothern, M.I.E.S., M.I.Mar.E. Size, 6 by 9¼ inches. Pages, 400. Illustrations, 230 (including many folding plates). New York, 1922: D. Van Nostrand Company.

Marine engineers generally are well acquainted with Mr. Sothern's previous books, "The Marine Steam Turbine," "Verbal Notes and Sketches for Marine Engineer Officers," etc., and this new volume is a welcome addition to this list.

In the new book Mr. Sothern covers practically all the phases of interest to the practical operating marine engineer who wishes to take up a study of Diesel engines with a view to being put in charge of these.

The book is divided into sections covering full descriptions of the various Diesel engines and their installation and practical operation, and also illustrating and explaining the various systems of starting gear in use, and the Diesel indicator diagrams and what they mean. Attention is also given in the book to the various auxiliaries in the engine room of a Diesel ship, and a number of questions and answers on Diesel oil engine practice are included which should prove of value to those taking examinations for certificates.

The section on indicator diagrams is particularly valuable as little information of this kind is at present available; the same might also be said of the article on fuel oil.

The book is splendidly illustrated by a large number of plans, sketches and large drawings, and is fully up to date, including such recent developments in Diesel engines as the Doxford and similar opposed piston engines, and the compound Still Diesel-steam engine.

In every way this book is a thoroughly satisfactory guide to a practical Diesel engine operator and should be in the hands of all those who contemplate taking charge of such machinery.

Very wisely the author has left out of his book the large and somewhat complicated question of heat stresses and the general questions of design such as propeller efficiency and revolutions and weights of the various types of engines as these are influenced by length of stroke, etc., and has confined himself to the information especially desired by those for whom the volume is prepared.

The Lloyd Sabaudo's new liner *Conte Verde*, sister ship of the *Conte Rosso*, was successfully launched at Glasgow, Scotland, on October 21. The Lloyd Sabaudo will place the *Conte Verde* in the New York-Mediterranean run beginning in the spring of next year.

*Naval architect, Munson Steamship Line, New York.

Captain William Lyons Made Commodore of American Hawaiian Fleet

Captain William Lyons was recently assigned to the command of the motorship *Californian*, at which time he was made commodore of the American-Hawaiian Steamship Company's fleet of twenty-one vessels. Captain Lyons became first officer of the American-Hawaiian steamship

Commodore William Lyons

Hawaiian in 1900 and has served continuously under the house flag of this company up to date. He was master of the steamers *Missourian* and *Montanan* when they were sunk by submarines during the late war. Under his command the *Californian* recently completed her maiden voyage of 21,000 miles from New York to the Pacific coast thence to Europe and return.

OBITUARY

Henry F. Miller, Philadelphia manager for Henry A. Kissel Company, dealer in ship supplies, recently died in that city following an operation. Mr. Miller was a member of the Maritime Exchange for many years representing S. P. Blackburn & Company and subsequently entered the employ of Kissel Company.

John R. Binning, manager for Canada and Newfoundland of Furness, Withy and Company, Ltd., recently died at Montreal at the age of fifty-six years. He was born at Hamilton, Scotland, and, after completing his education, was employed for a short time in the ship business in Scotland. He entered the service of the Canadian Pacific Railway in 1888 and ten years later became assistant manager of Furness, Withy and Company, Ltd., which position he held until 1903 when he was made general manager with headquarters in Montreal. In recognition of the service he rendered during the war, Mr. Binning in 1920 was appointed to the office of manager for Canada and Newfoundland.

PERSONAL MENTION

O. L. Smith, Jr., formerly manager of the Black Diamond Steamship Corporation's Baltimore office, has been promoted to the position of general manager of the Black Diamond Steamship Corporation at the head office in New York.

Arthur A. Grant, who resigned as vice-president and southern resident director of the Sinclair Refining Company with headquarters at New Orleans, has been appointed general manager of the Jahncke Dry Docks, Inc., of the same port.

Frederick I. Thompson, commissioner of the United States Shipping Board, representing the interests of the Gulf section, will retire from the Board within a short time. Mr. Thompson has recently become owner of the *Birmingham Herald*, which has made it necessary to give up his duties on the Shipping Board.

Captain R. L. Martin recently retired from the Robert Dollar Line after fifteen years' service, the last few years of which he served as marine superintendent at Vancouver. It is stated that he will organize a new shipping firm in association with Melville Dollar who has also retired from the Robert Dollar Company.

William Simmons, of the Simmons Transportation Company, the Jarvis Lighterage Company, Lee and Simmons, Inc., and a former president of the Maritime Exchange, was elected a commissioner of pilots at a special meeting of the Chamber of Commerce of the State of New York to serve for three years in place of Arthur M. Smith who died recently.

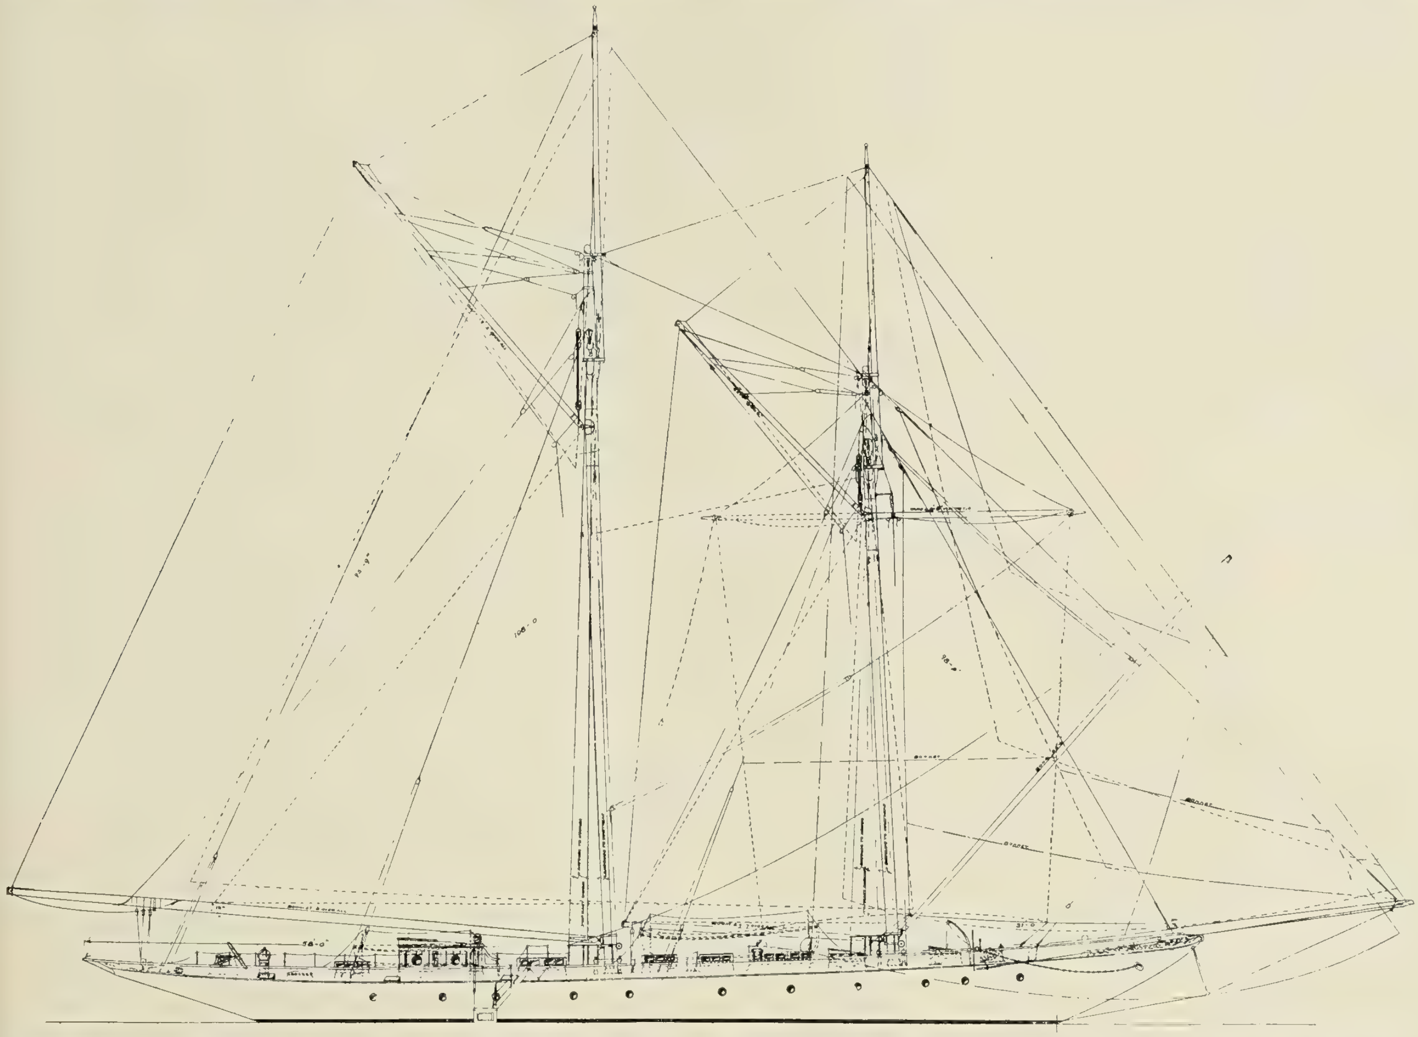
Hugo P. Frear, naval architect of the Bethlehem Shipbuilding Corporation, Bethlehem, Pa., and Ernest H. Rigg, naval architect of the New York Shipbuilding Corporation, Camden, N. J., have been appointed delegates to represent the American Marine Association at an informal conference on standardization called by Secretary Hoover of the Department of Commerce and to be held in the auditorium of the Grand Central Palace, New York, on Friday, November 10.

F. P. Guthrie, head of the radio division operating department of the United States Shipping Board Emergency Fleet Corporation, has been designated by Chairman Lasker as the representative of the Shipping Board and Emergency Fleet Corporation to serve as a member of the inter-departmental committee on electrical communications. Mr. Guthrie was a delegate to the Inter-Allied Communication Conference at Paris last summer. He has been with the Emergency Fleet Corporation since May, 1919.

R. Stanley Dollar, one of the largest stockholders of the Pacific Steamship Company (the Admiral Line) but who has not been active in its affairs, has been induced to take up his residence in Seattle, Wash., and to form a new company to be known as the Admiral-Oriental Line to which the Shipping Board allocated its ships running out of Seattle. Mr. Dollar, who is one of the most experienced operators in the Far Eastern trade, will hold the position of president of the new line devoting his entire time to the enterprise. A. F. Haines, who formerly managed the government ships for the Pacific Steamship Company, has been made vice-president of the new company. Mr. Dollar retains his interest in the Pacific Steamship Company, the present arrangement merely bringing all the government ships under the control of a company that will devote its entire time to their operation.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry



OUTBOARD profile of two-masted steel auxiliary schooner designed by Theodore E. Ferris, naval architect and marine engineer, New York City, for William P. Adams, Esq., of Chicago, Ill. Vessel will be 125 feet over all, driven by oil engines, and bids for construction have been asked. She will cost about $100,000.

Contract for Another 12,000-Ton Steel Bulk Freighter Awarded Great Lakes Engineering Works

THE placing of another contract for the construction of a 12,000-ton steamer, as an addition to the bulk freight fleet, is the latest announcement from the Great Lakes district. The Great Lakes Engineering Works, of Detroit, Mich., is given as the successful shipyard, the new vessel to be built for the Cleveland-Cliffs Iron Company. Although official figures were not given, it is understood that the cost of the ship will be close to $800,000.

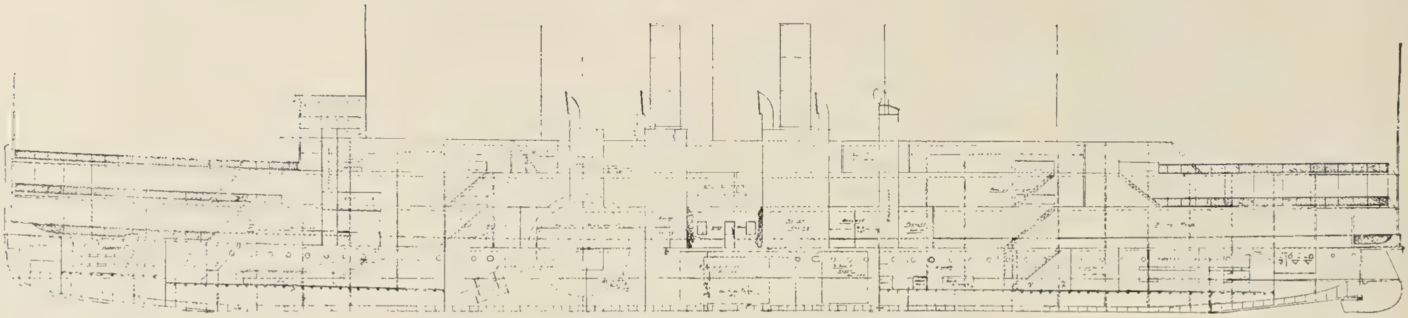
The new vessel will be a duplicate of the steamer *Pontiac,* of the iron company's fleet, being 600 feet over all length, 580 feet keel, 60 feet beam and 32 feet deep. She will be driven by a triple expansion engine, steam being furnished by three Scotch boilers.

This contract makes eight steamers of the 600-foot class that have been ordered since last May. Two of the boats will be built by the Great Lakes Engineering Works, five by the American Shipbuilding Company and one by the Toledo Shipbuilding Company. All the new boats will be operated in Cleveland. All the big freighters are for 1923 delivery except the steamer *James McNaughton,* which is building for the Wilson Transit Company by the Great Lakes Engineering Works.

Contract Reported Placed for the Red "D" Line Steamers

A PERSISTENT report in marine circles, credits the New York Shipbuilding Corporation with having been awarded the contract for the construction of one and possibly two new steel passenger and cargo ships for the Red "D" Line. While official information was withheld, there was a strong impression that the award has been made, the cost of each ship being unofficially estimated as in the neighborhood of $700,000. It is understood that propulsion will be by turbine engines.

The vessel will have an over all length of 320 feet, according to specifications issued recently, and will be of the two-deck shelter deck type, driven by twin screws.



Inboard Elevation of Proposed New Steamer

Specifications Prepared for Oil Burning, Side Wheeler to Be Added to Hudson Day Line Fleet

Vessel Will Have Length of 338 Feet, Propelled by Triple Expansion Steam Engines—Is to Have Two Single and Two Double Ended Scotch Boilers

PLANS and specifications were prepared by J. W. Millard & Brother, naval architects, 17 State street, New York City, for the construction of a new paddle wheel steel steamer for the Hudson River Day Line, bids having been received on October 20. The principal dimensions of the proposed steamer are length over all 338 feet, extreme breadth 76 feet, depth molded to main deck at side guard 13 feet 8 inches. The vessel will be propelled by a diagonal inclined triple expansion steam engine and she will be of a type equal to the steamer *Robert Fulton.*

Hull

The hull is to be built of steel on the transverse system and there will be two keelsons on each side of the middle line worked over the floors amidships. Tanks for the storage of oil fuel are to be built in the hull on each side in the forward boiler room.

There are to be five cylindrical fresh water tanks built of No. 12 B. W. G. steel plates, galvanized with single riveted seams and double riveted butt straps calked and made watertight.

Equipment

Chocks, cleats and fairleads are to be of cast steel of approved pattern similar to those on the steamer *Washington Irving.* There will be provided and fitted ready for use four pairs of davits for 22-foot lifeboats made of 3½-inch double extra thick steel pipe. The anchor davit of 3½-inch double extra thick steel pipe is to be complete with all fittings similar to that on the steamer *Robert Fulton.*

There is to be an American Engineering Company or other approved combination hand and steam power capstan located on the main deck forward. The capstan is to be fitted with a wildcat for 1-inch diameter anchor chain and to be large enough to handle the anchor and 7-inch lines.

Two approved hand deck pumps of brass of suitable size for the steamer, with their necessary sea and bilge valves and pipes, are to be fitted complete, as required by law.

The steamer is to have four metallic lifeboats of approximately 20 feet by 6 feet by 2 feet 5 inches; also one working boat 14 feet by 4 feet 6 inches by 1 foot 9 inches.

One 1,200-pound stockless anchor and one 600-pound stockless anchor with 60 fathoms, of 1-inch diameter, galvanized crane chain with proper shackles, etc., are to be supplied.

Machinery

The vessel will be propelled by paddle wheels of the feathering type, driven by an engine of the diagonally inclined, triple expansion, surface condensing type. The high pressure cylinder is to be in the center with one intermediate pressure cylinder on one side and one low pressure cylinder on the other. The general design of the engine and the character of workmanship and finish of all the machinery is to be like that of the steamer *Washington Irving.* The engine, in all its parts, is to be proportioned for a working boiler pressure of 180 pounds per square inch and 40 revolutions per minute. The paddle wheels are to be about 22 feet 5 inches in diameter, each having nine paddles about 12 feet 6 inches long by 3 feet 9 inches wide.

The main condenser will be separate from the main engine, built of wrought steel plate and will have about 5,800 square feet of cooling surface.

There will be one centrifugal circulating pump, worked by a vertical steam engine; a complete set of independent air, feed, sanitary, fire and trim tank pumps, electric light plant, steam steering engine, feed water heater, steam fan blowers for forced draft and ventilation, oil heaters and pumps, and such other supplementary machinery, instruments, etc., as may be necessary to make the installation complete.

Boilers

There will be two single ended and two double ended cylindrical, horizontal, Scotch type boilers to be allowed a working pressure of 180 pounds. Each boiler is to be 12 feet 1 inch inside diameter and 11 feet 4 inches length over top head for the single ended boilers and 22 feet over the top head for the double ended boilers.

Each single ended boiler is to have about 2,100 square feet of heating surface and each double ended boiled about 4,200 square feet of heating surface.

Each single ended boiler will have two furnaces and each double ended boiler four furnaces, 42 inches least inside diameter, and arranged to be taken out and revised without disturbing the boilers.

Fuel Oil Burning System

The steamer is to be furnished and fitted complete with the White Fuel Oil Engineering Corporation mechanical fuel oil burning system and there will be installed in the engine or boiler room two fuel oil pumps, three fuel oil heaters, duplex suction and discharge strainers, with all usual fittings.

Contract for New Steamer Awarded Bath Iron Works

A CONTRACT for the construction of a new passenger vessel for the New Bedford, Martha's Vineyard and Nantucket Steamboat Company, a subsidiary of the New England Steamship Company, has been awarded to Bath Iron Works, of Bath, Me. The new vessel will be a single-screw boat 200 feet in length, driven by a triple expansion steam engine.

Half A Million May Be Cost of Three-Ship Job

A HALF million dollar ship conversion job, involving three unfinished ships at Pascagoula, Miss., will be undertaken in the near future, according to latest reports from that city. The ships involved are hulls of steel construction, about 385 feet in length, built by the International Shipbuilding Company, of Pascagoula. They were originally intended for steam propulsion, one ship being so far completed that she will be finished as intended, the other two hulls, which are only partially completed, are to be equipped with Diesel engines.

Plans and specifications for the reconditioning work were prepared by Whittelsey & Whittelsey, naval architects, of 17 Battery Place, New York, tenders being received on Monday, October 16.

It is understood that the three hulls have been launched and were designed as cargo ships.

Steamer Covedale Will Be Converted to Oil Engines

BIDS have been received by the Munson Line for the conversion of the steamship *Covedale.* One of the two Scotch boilers now in the ship will be retained, as will most of the steam auxiliaries. New foundations for the engine and a number of new auxiliaries will be installed, the new propulsion to consist of one 900-brake horsepower McIntosh & Seymour Diesel engine, which was purchased by the Munson Line from the Shipping Board.

Tenders submitted October 5 were:

Tebo, $56,860, 58 working days.

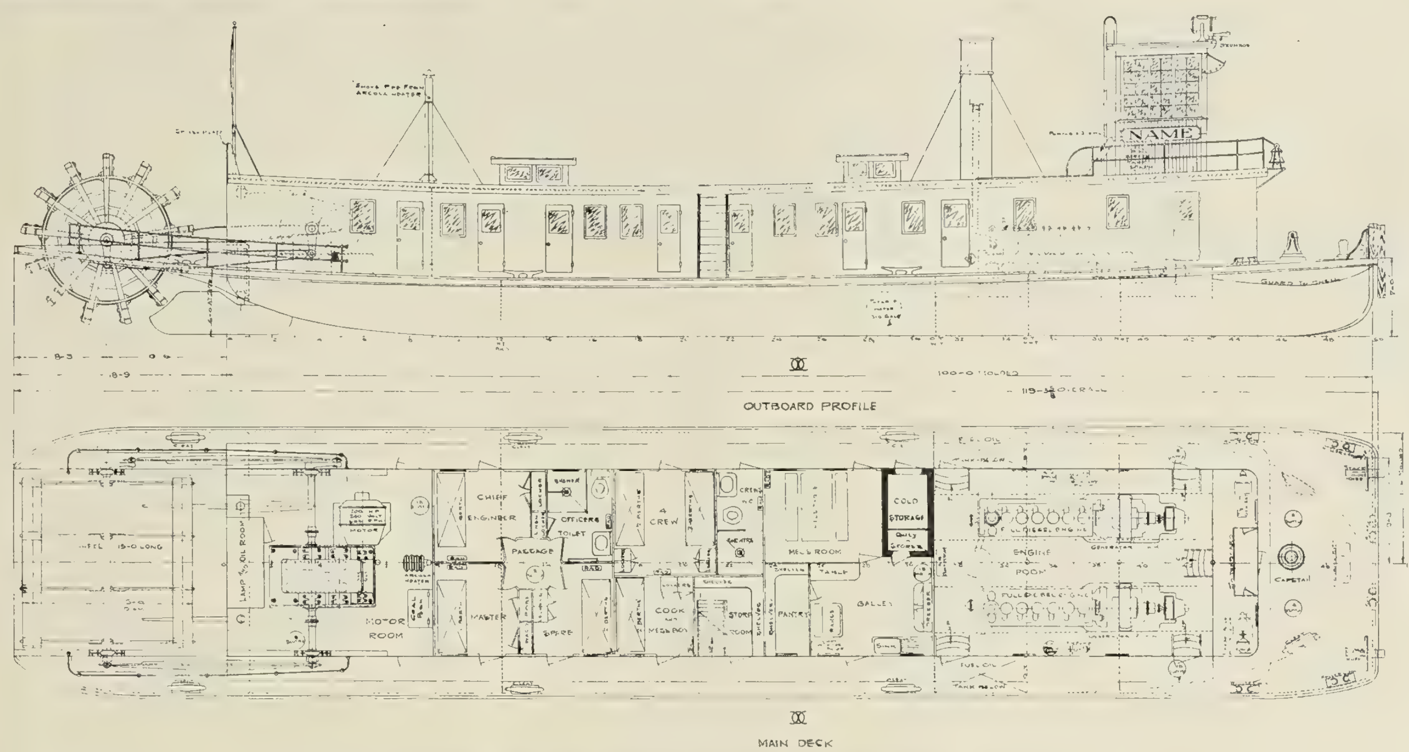
New York Harbor, $64,688, 50 cont. running days.

Federal, $68,000, 60 days.

Newport News, $68,000, 75 cont. running days.

New York Ship, $78,500, 90 running days.

Merchant Ship, $79,000, 14 weeks.



Profile and Deck Plan of Diesel-Electric River Tug

Charles Ward Engineering Works Submits Low Price for Building 100-Foot Diesel Electric Towboat

THE CHARLES WARD ENGINEERING WORKS, of Charleston, W. Va., submitted the lowest price for the construction of a 100-foot Diesel electric towboat for the U. S. Engineer Office, Mobile, Ala., at the opening of tenders on October 10. The Ward Company gave a price of $89,000 and 200 days, with Winton 6-cylinder 4-cycle main engines, Westinghouse main electrical machinery and Fawcas reduction gears.

The proposed vessel will have an over all length of 119 feet 3⅝ inches, breadth molded 23 feet, depth 5 feet, draft loaded 3 feet. She will be built according to American Bureau of Shipping Rules. Two Diesel engines are to be installed and they are to be a standard commercial product of American manufacture. Prices submitted provided for Worthington, Winton, McIntosh & Seymour and New London Ship & Engine Company types of main engines.

Two Tankers May Be Converted From Turbines to Diesels

GEORGE G. SHARP, naval architect, and marine engineer, of 30 Church street, New York City, has in hand a proposition for the conversion of two 7,500-ton tankers from geared turbine drive to Diesel drive. The engines to be installed are to be about 2,500 brake horsepower each.

Steamer Aztic Awarded Newport News Shipyard

ANNOUNCEMENT is made of the awarding of the contract for damage repairs on the steamship *Aztic*, to the Newport News Shipbuilding Company, on a bid of $14,643 and 12 days' time. Tenders were opened by Harald Nervik and R. Beylegaard, owners' representatives office, 59 Pearl street, New York. The prices submitted were as follows:

Sun Shipbuilding Co.......	$13,894	14 days
Tietjen & Lang............	14.110	17 days
Newport News Shipb'd'g Co.	14,643	12 days
Morse Dry Dock & Rep. Co.	16,000	17 days
Bethlehem Shipb'd'g Corp..	18,977	16 days

Three Contracts Awarded Johnson Plant, New Orleans

A CONTRACT to repair the damage caused by a hurricane to the United States Shipping Board tanker *Danville*, while the vessel was in Tampico Harbor, has been awarded the Johnson Iron Works, New Orleans, La., on a figure of $14,923.

The Johnson plant also has the Mississippi Warrior tug *Gypsum Prince* for repairs to machinery and hull, amounting to about $3,000. The Shipping Board steamship *Lake Clearport* was drydocked at the same yard for minor repairs.

Oil Conversion Job

The Joseph Frolich Iron Works, Inc., of New Orleans, La., has been awarded the contract to convert the tug *Panther*, owned by the Alexander Towing Company, of New Orleans, into an oil burner.

The Frolich Works is also busy with its two harbor floating repair plants, making repairs to the following ships: *Yumi*, of the Mexican Fruit Company; the *Ciba* and the *Caloria*, of the Vaccaro Brothers; the *Olancha*, of the Cuymel Fruit Company; the *Jacob Luckenbach*, of the Luckenbach Lines.

Buffalo Engineer Office Will Build Three Steel Scows

UNITED STATES ENGINEER OFFICE, of Buffalo, N. Y., will receive sealed proposals until 11 A. M. on November 6 for the construction of three 400 cubic yard steel dump scows. The boats are to have a length molded of 110 feet, breadth molded 32 feet, and unless otherwise specified, shall be built to the American Bureau of Shipping rules.

Contract Placed for Three Steel Bulk Oil Barges

A CONTRACT has been awarded the Alex Dussel Iron Works, of New Orleans, La., for the construction of two steel oil barges, 100 feet by 22 feet by 5 feet, with six compartments, and one 100 feet by 16 feet by 5 feet, with five compartments, for the Consolidated Company, Inc., of Plaquemine, La.; price $17,000. The company will fabricate the steel at their plant on Clio Street and assemble the boats on the river front.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Drydocked, New Orleans, La.—Tanker Danville, damaged by a storm, went to New Orleans to be drydocked.

Repairs to Steam Schooner, North Vancouver.—Steam schooner Fred Baxter went to Wallace Dry Dock to undergo repairs.

Motorship Drydocked, Galveston, Tex.—Motorship Whipple, of the Snyder Banana Company, went to Galveston to be drydocked.

Steam Schooner Drydocked, Portland, Ore.—Steam schooner Daisy Freeman went on drydock at Portland to install a new propeller.

Barge Drydocked, Chester, Pa.—The Atlantic Refining Company's motor barge No. 68, went to the Sun Shipyard, Chester, for repairs.

General Repairs, Jacksonville, Fla.—The Dio, consigned to Southern Shipping Company, went on drydock at Jacksonville for general repairs.

Schooner Drydocked, Portland, Ore.—The schooner Dauntless was lifted on the Port of Portland drydock for cleaning and painting the hull.

Steamer Repairs, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company was awarded repairs on the Shipping Board steamer Lake Giltedge.

Repairs to Tanker, Chester, Pa.—Tanker R. D. Leonard, of the Atlantic Refining Company's fleet, was drydocked at Sun Shipyard for miscellaneous repairs.

Steamer Inspection, Long Island, N. Y.—Steamer Medon went to Hunter's Point drydock to be inspected by representatives of the Alaska Steamship Company.

Steamer Reconditioned, San Pedro, Cal.—The Elabe, of the same company, went to the Los Angeles Shipbuilding and Dry Dock Corporation to be reconditioned.

Battleship Drydocked, San Francisco, Cal.—The dreadnaught New Mexico of the Pacific fleet went to the Hunters Point drydock to have new propeller blade installed.

Reconditioned for Lumber Trade, West Coast.—The El Cedaro, of the Los Angeles Lumber Products Company, will be drydocked soon to be reconditioned for the lumber trade.

Freighter Converted to Oil Burner, San Francisco, Cal.—Matson freighter Coverun went on ways at Bethlehem shipbuilding plant to undergo a change from coal to oil burning.

Steamer Drydocked, Seattle, Wash.—Steamship Queen, of the Pacific Steamship Company, went to Seattle to be drydocked for survey, as a result of damage made by grounding.

Negotiating for Tanker, San Francisco, Cal.—The Associated Oil Company, of San Francisco, is reported as negotiating for the purchase of a 4,000-ton tanker on the East Coast.

Conversion to Oil Tanker, West Coast.—Robert Dollar Line will convert the bark William Dollar into an oil tanker for the purpose of hauling fuel from the Pacific Coast to the Orient.

Lighthouse Tender Drydocked, Savannah, Ga.—Lighthouse tender Cypress went to the Wilkinson Machine Company to be scraped, painted and to have her engines thoroughly overhauled.

Repairs to Steamer, Mobile, Ala.—Shipping Board steamer Salvation Lass went to plant of the Alabama Dry Dock Company for minor repairs to her boiler, renewing a number of bad tubes.

Auxiliary Schooner Surveyed, Seattle, Wash.—The auxiliary power schooner Anvil went to Seattle to be surveyed as a result of striking Kelp reef and having her starboard bow considerably damaged.

Installation of Diesel Engines, Camden, N. J.—New York Shipbuilding Corporation will install Diesel engines on the steamship Jacksonville, purchased from the Shipping Board, and will offer her for sale.

Work on Barge, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company was awarded following work on the barge Oriole; installation of new boiler, together with necessary braces, hood, umbrella, stack, etc.

New Ferry Ordered, Detroit, Mich.—Great Lakes Engineering Works were awarded contract to build a ferry steamer for the Detroit-Walkerville route. She will have a capacity for forty-five automobiles and 2,000 passengers.

Cleaning and Painting Contracts, California.—Southern Pacific ferryboat Santa Clara went on drydock to undergo cleaning and painting and the Union Oil Company's carrier Oleum went on the Moore ways to also be cleaned and painted.

Reconditioning Contract, San Francisco, Cal.—The contract for reconditioning the two full-rigged ships, Arrapahoe and Edward Sewell, recently purchased by the Alaska Packers' Association, was awarded to the Moore Shipbuilding Company.

Scraping and Painting, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company was awarded contract for scraping and painting the tug Echo. Specifications also called for welding seams on front head of boiler and machinery repairs.

Repair Contracts, West Coast.—The General Engineering Company, of San Francisco, Cal., low bidder, was awarded general repairing work on three steamers, President Lincoln, Colombia and Wilhemina. Prices, in succession, $2,485, $595 and $158.50.

Shipyard Contracts, West Coast.—The Moore Shipbuilding Company, of Oakland, Cal., was awarded the following contracts: Steamers Floridian, West Katan, dredger San Pablo, steamers Covina, Coquille, tanker La Purisima and barkentine City of Sydney.

Barges Repaired, Mobile, Ala.—Barges Juniata and Susquehanna, of the Gulf Refining Company, went on the large dock of the Alabama Dry Dock & Shipbuilding Company. They require reconditioning of a number of shell plates, frames, rail stanchions, etc.

Steamer Drydocked, San Francisco, Cal.—Admiral Line steamer Admiral Schley went to Union Iron Works to be cleaned and painted. Bottom was scraped and cleaned, vessel to have two new coats of paint. Two new propellers replaced those already on the ship.

Repair Work, San Francisco, Cal.—The Moore Shipbuilding Company was awarded the following contracts: U. S. army transport Grant, to overhaul engines, etc., price $10,000; steamer Manukai, general overhauling, and steamers Edna and Alaskan, general repairs.

Repairs to Steamer, Quincy, Mass.—The Bethlehem plant at Quincy was awarded the contract for the following repairs to the steamer Calvin Austin, which went ashore in the Cape Cod Canal; replacing of stern frame, new rudder, keel plates and repairs to the forward section.

Steamer Reconditioned, New Orleans, La.—Contract for reconditioning United States Shipping Board steamer West Wauna was awarded to Jahncke Dry Dock Company. Overhauling included general repairs and furnishing and installing of a new set of Falk gears. Price $17,037.

Contract Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company was awarded the contract for installing a new rudder and miscellaneous bottom work on the towboat Montgomery and also for repairs to the towboat Demopolis, both of the Mississippi-Warrior Line.

Reconditioning Contracts, New Orleans, La.—The Johnson Iron Works was awarded the contracts for docking and repairs to Mississippi Warrior tugs, the Baton Rouge and Cairo, steamship Craster Hall, steamships Isabella and Manta, steamship Blue Hill, towboats Ruth and Cadmaus.

Painting and General Repairs, Mobile, Ala.—Gulf Refining Company's tug Senator Bailey went on dock of the Alabama Dry Dock Company for painting; installing new tail shaft; repairs around the hull and engine, including furnishing and installing new air pump to replace the one previously on board.

Barge Launched, New Orleans, La.—The Johnson Iron Works, Dry Dock and Shipbuilding Company, Inc., launched the last of the six barges to be sent to the United States Engineers at Mobile, Ala. The barges are made of steel, two having cabins, the last being 87 feet long, 28 feet 4 inches beam and 7 feet deep.

Contract Awarded, Brooklyn, N. Y.—Robins plant of the Todd Shipyards Corporation was awarded the contract for reconditioning the Texas Company's steel tanker Louisiana. In addition to reconditioning, Todd mechanical fuel oil burners and necessary auxiliary equipment will be installed. Price $100,000.

Tanker Repairs, Mobile, Ala.—Shipping Board steamer Duquesne was awarded to Todd Shipbuilding and Dry Dock plant, Mobile, for repairs, including installing of new set of reduction gears and extensive repairs on main turbines, necessitating removal from vessel of practically all propelling machinery.

Miscellaneous Repairs to Steamer, Chester, Pa.—Sun Shipbuilding Company was lowest bidder for contract to repair Japanese steamship Kashu Maru, damaged in collision. Sun yard bid $4,435 for repairs to counter, renewing several plates, fairing others, reconditioning steering gear and making miscellaneous repairs.

New Steel Barges, Pittsburgh, Pa.—American Steel and Wire Company has ordered twenty new steel barges from the American Bridge Company at a cost of $340,000. They are to be 175 feet long, twenty-six feet wide and eleven feet deep, and will be used for transport of coal and billets in the Monongahela and Allegheny rivers.

Repair Contracts, Hoboken, N. J.—The Tietjen & Lang plant of Todd Shipyards Corporation was awarded the contract for rebuilding the hull of the Mallory Line tug President; cost about $12,000. Same yard also reconditioned the ferryboat Syracuse and barges of the Clyde Line, Southern Pacific Company and D., L. & W. and Lehigh Valley Railroads.

Conversion Contracts, Brooklyn, N. Y., and Hoboken, N. J.—Contract for conversion of four ships of the Southern Pacific Steamship Company from coal to oil burning vessels was awarded to the Todd Shipyards Corporation; total cost about $336,800. Ships involved were El Siglo and El Cid, Robins Yard, Brooklyn, N. Y.; and El Dia and El Rio, Tietjen & Lang plant, Hoboken, N. J.

Steamship Overhauled, Camden, N. J.—Passenger and freight steamship Jacksonville, owned by the Merchants' and Miners' Transportation Company of Baltimore, was towed to yards of the New York Shipbuilding Corporation for extensive alterations to passenger quarters and a complete overhauling. She will probably be converted from triple expansion steam engine to Diesel-engine propulsion.

Reconditioning Jobs.—Bids submitted for repairs and reconditioning for three ships were as follows: Foreign Transport & Mercantile Corporation steamship Winnebago, Staten Island Shipbuilding Company, $4,721—33 days; United Fruit Ship Norma of Delaware, Morse Dry Dock & Repair Company, $14,650; and Baltimore & Carolina Steamship Company's steamer Tipton, Crook Shipyard, $212,790.

Installation of Boilers, Pittsburgh, Pa.—The Pearson Manufacturing Company received the contract to install a battery of three boilers on steamer National of the J. K. Davison & Brothers. They will be of the two-flue type, 38 inches wide and 26 feet long. The company also completed repairs to the boilers and machinery of the steamer Hibernia, owned by the Equitable Towing and Transportation Company.

Construction Contract, Amsterdam, Holland.—The Nederland Shipbuilding Company (Nederlandsche Scheepsbouw-Maatschappy), Amsterdam, have obtained an order from the Colonial Department for a cable-ship for the East Indies, named Zuiderkruis. The ship's dimensions are to be as follows: Length over all, 290 feet 10 inches; breadth molded 36 feet 9 inches; depth 22 feet 2 inches. The engine installation will be supplied by Werkspoor, Amsterdam.

Work on Great Lakes.—Great Lakes Engineering Works, Ecorse, Mich., was awarded the following contracts: Construction of 12,000 ton steamer James McNaughton; large amount of work on boats of smaller class; automobile carrier Fellowcraft, minor repairs; steamer M. G. Hausler, repairs to nine plates; tug Sidney T. Smith, to receive new stern and general overhauling; steamer Wesee and barge Harsen, for repairs; and seaplane, the Buckeye, engine overhauling.

SHIPYARDS AND DRYDOCKS

New Drydock, Staten Island, N. Y.—The new drydock of the New York Harbor Dry Dock Company, adjoining the new city piers, Clifton, S. I., was put in operation on Monday, October 16, a Standard Oil barge being the first boat to be lifted. The dock is 585 feet in length, 85 feet 7 inches wide between wings at bottom, 23 feet draft over keel blocks at low tide and will take ships up to 13,000 gross tons.

Plans Building Drydock, New Orleans, La.—The Algiers Dry Dock & Repair Company, of New Orleans, Edgar Berthaut, president, is planning to build a floating all-steel drydock capable of accommodating vessels up to 10,000 deadweight tons. The drydock will be 250 feet in length by 54 feet and will be operated by electric-driven centifrugal pumps. It is to cost about $400,000. The concern is contemplating increasing its capitalization to $500,000.

New Drydock, New Orleans, La.—The Algiers Dry Dock and Ship Repair Company, Inc., has been work on another floating all-steel drydock, capable of accommodating vessels up to 10,000 deadweight tons and plan to increase the capital stock of the concern from $100,000 to $500,000. The new dock, when completed, will be more than four times as large as the present dock, which is capable of receiving ships up to 2,000 tons, and will represent a cost of approximately $400,000, according to officials of the company. It is expected that the new dock will be completed by April 1, 1923.

PORT IMPROVEMENTS

Quay Walls, Montreal, Que.—Harbor Commissioners of Montreal awarded contract to Atlas Construction Company, Belmont street, for extending high quay walls between Sections 25 and 35, 4,500 feet long. Price $450,000.

Bulkhead, Chicago, Ill.—South Park Commissioners, Fifty-seventh street and Cottage Grove avenue, awarded the contract for 7,200 linear feet bulkhead to Great Lakes Dredge and Dock Company, 104 South Michigan avenue.

Contract Awarded, New York City.—The Morris & Cummings Dredging Company, 17 State street, New York, was awarded a contract by the Pennsylvania Railroad, Broad Street Station, Philadelphia, for dredging 180,000 cubic yards in South Amboy Harbor.

Contract Awarded, Norfolk, Va.—The contract for dredging the Norfolk channel to 40 feet in depth and widening to the eastward from the mouth to the junction of the Eastern and Southern Branches of the Elizabeth River, was awarded to the Fred E. Jones Dredging Company.

Developments of Harbor, Hamilton, Ont.—Hamilton Harbor Commission is having plans prepared for harbor front development and reclamation of land. Plans to proceed as soon as possible with first unit, costing $1,077,000, mostly reclamation work. Total, $13,000,000. A. Guy, chairman; E. V. Gray, city engineer; Gore, Nasmith & Storrie, Confederation Life Building, Toronto, engineers.

Harbor Improvements, Montreal, Canada.—Dominion Government, Ottawa, Ont., approved the following works for Montreal Harbor: Extending Jacques Cartier Pier 300 feet, $200,000; extending Alexander Pier 300 feet, $450,000; extending King Edward Pier 300 feet, $450,000; improving channel approach to Bickerdike Pier, $97,850; paving and extending Harbor Ry. terminals to new wharf levels, east of Section 25, $50,000. W. L. McDougall, chairman of Board of Harbor Commissioners; R. Harvie, chief engineer.

GOVERNMENT WORK

Barge, Montgomery, Ala.—Constructing Quartermaster, Montgomery, plans steel barge.

Catamarans, Savannah, Ga.—Constructing Quartermaster, Savannah, plans pontoon catamarans and pipe for dredge Morgan.

Pier Extension, Puget Sound, Wash.—Specification 4707—Bureau of Yards and Docks, Navy Department, Washington, D. C., plans extending Pier 4.

Plans for Dredging, Puget Sound, Wash.—Specification 4708—Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging in Sound.

Barges, Florence, Ala.—U. S. Engineer awarded contract for 2 steel barges to Charles Ward Engineering Company, South Side, Charleston, W. Va. Price $34,000.

Dredge Pontoons, Etc., Mobile, Ala.—Penn Bridge Company, Beaver Falls, Pa., was awarded the contract for dredge pontoons and discharge pipe for U. S. Dredge Wahalak, by U. S. Engineer, Mobile. Price $28,903.

Steel Gates, Nashville, Tenn.—U. S. Engineer awarded contract to Penn Bridge Company, Beaver Falls, Pa., for steel gates for Lock F, Cumberland River. Price $22,783.

Barges, New Orleans, La.—U. S. Engineer, 329 Customhouse, awarded the contract for 2 steel oil barges in Mississippi River, to Midland Barge Company, Midland, Pa. Price $59,850.

Jetty Repairs, Jacksonville, Fla.—Waterfront Construction Company, Charleston, S. C., was awarded the contract for jetty repairs in St. Johns River, by U. S. Engineer. Price $5.87 per ton.

Catamarans, Portland, Ore.—The Williamette Iron and Steel Works, Portland, was awarded the contract for 80 steel pontoon catamarans for dredges Multnomah and Wahkiakum, by U. S. Engineer, Second District. Price $49,600.

Contract Awarded, New Orleans, La.—U. S. Engineer, 329 Custom House, awarded the contract for furnishing stone for Southwest Pass, Head of Pass and South Pass, Mississippi River, to O. F. Barrett, 2303 Grandview avenue, Cincinnati, Ohio. Price $216,480.

Contract Awarded, Philadelphia, Pa.—American Dredging Company, Mariner and Merchant Building, was awarded the contract for dredging in Delaware River on Bellevue, Cherry and Liston ranges, by U. S. Engineer, Witherspoon Building. Price $616,786.

Quay Walls, Etc., Pearl Harbor.—Specification 4591—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded contract to E. J. Lord, McCandless Building, Honolulu, for quay walls and pier at Naval operating base at Pearl Harbor. Price $749,160; time 450 days.

Breakwater Construction, Indiana.—U. S. Engineer's Office, Room 1201, 537 South Dearborn St., Chicago, Ill., will receive sealed proposals for constructing concrete caisson breakwater at Indiana Harbor, Indiana, until 10 A. M., November 6, 1922. Further information on application.

Contract Awarded, Hampton Roads, Va.—Specification 4699—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded the contract for riprap protection for breakwater pier at Naval Operating Base, to Arundel Corporation, Pier 2, Pratt street, Baltimore, Md. Price $150,000.

Dredging, Philadelphia, Pa.—U. S. Engineer, Witherspoon Building, awarded contract to American Dredging Company, Mariner and Merchant Building, for dredging in Delaware River, on Bellevue, Cherry and Liston ranges. Price $616,786.

NEW INCORPORATIONS

Yonkers & Alpine Ferry Company, capital $300,000, chartered at Albany. Incorporators: W. F. Dee, J. Williamson and J. Schwartz.

Donnelly Dry Dock Company, of Manhattan, capital $250,000, chartered at Albany. Incorporators: W. T. and N. E. Donnelly and D. W. Barnes.

The Susquehanna Line, of New York, capital $100,000, chartered under Delaware laws, to do steamship business. The Susquehanna Steamship Company operates Shipping Board vessels from New York and Philadelphia to Scandinavian and Baltic ports.

FOREIGN ACTIVITIES

Steamship Launched, Germany.—The new North German Lloyd steamship Werra has been successfully launched. The Werra will be used in the line's China service. She is a vessel of approximately 9,000 gross tons, with a 12½-knot speed, and will carry sixty cabin and 1,400 third class passengers.

Construction Contract, Amsterdam, Holland.—The Nederland Shipbuilding Company (Nederlandsche Scheepsbouw-Maatschappy) Amsterdam, have obtained an order from the Colonial Department for a cable-ship for the East Indies, named Zuiderkruis. The ship's dimensions are to be as follows: Length over all, 290 feet 10 inches; breadth molded, 36 feet 9 inches; depth, 22 feet 2 inches. The engine installation will be supplied by Werkspoor, Amsterdam.

Ship Construction, Scotland.—Announcement is made that the Commonwealth Government of Australia has ordered five passenger liners of 13,850 gross tons to be built on the Clyde for its service from London to Fremantle via the Suez Canal, including a stop at Colombo, Ceylon, which is reached in 20 days. A special feature of these ships is that with the exception of six cabins for 12 passengers, the whole accommodation is for third class passengers, totaling about 700.

Ship Contract, England.—Elders & Fyffes, Ltd., British subsidiary of the United Fruit Company, have placed an order with Cammell, Laird & Company, of Birkenhead, for two new ships. The vessels will be mainly for the transportation of fruit, designed to handle 100,000 bunches of bananas each and having limited passenger accommodations. Their capacity will be about 5,000 gross tons and will run in the company's service between the banana fields and the United Kingdom and Continental ports. The United Fruit Company some time ago announced the placing of orders for two Diesel engined ships for its American trade.

Trial Trip, Holland.—According to advices received by the Holland-America Line, the trial runs of the company's new twin screw steamship Volendam have been very successful. The steamer satisfied every expectation as to speed and maneuvering and has proceeded to the Holland-America Line docks at Rotterdam, where she will be finished. The Volendam is an oil burning passenger steamer of 15,550 tons register, 24,000 tons displacement, and is to be added to the New York passenger service of the company. She is equipped with all modern conveniences. The vessel is scheduled to sail from Rotterdam for New York on her maiden voyage November 4. Her return voyage from New York to Rotterdam, via Plymouth and Boulogne-sur-Mer, will be November 21.

Trials of Tankship, England.—The steamship Solen, one of several oil tankships built by Messrs. Swan, Hunter & Wigham Richardson, Ltd., for the Anglo-Saxon Petroleum Co., Ltd., of London, has run successful trials. The speed attained during a series of runs on the measured mile was over 12 knots. The Solen will carry benzine in bulk and is built on Isherwood's system of longitudinal framing to Lloyd's highest class. Her dimensions are 427 feet in length, breadth 53 feet 4 inches and molded depth to the upper deck 31 feet.

Construction of 24-Inch Hydraulic Dredge Planned

PLANS and specifications are being prepared for the construction of a 24-inch hydraulic dredge for the United States Engineer Office, Room 405 Customhouse, Cincinnati, Ohio. The drawings and specifications are being worked up in the office of the Chief of Engineers, Washington, D. C., and it is expected they will be issued from the Cincinnati office in the near future.

BUSINESS NOTES

The Peabody Engineering Corporation has removed its office from 331 Madison Avenue to 110 E. 42nd Street, New York. They have taken considerably more space than their former office.

The Norman W. Henley Publishing Company, 2-4 and 6 West 45th Street, New York City, N. Y., will gladly send free to readers of Marine Engineering and Shipping Age a copy of their 1923 "Latest Catalogue of Practical and Radio Book," which they have just issued.

Lynn W. Nones has been appointed Eastern Manager of the Marine Department of the Diamond Power Specialty Corporation, with offices at 90 West Street, New York City. Mr. Nones was formerly manager of the Marine Department of the Griscom-Russel Company and was associated with them three and a half years. Previous to this connection Mr. Nones was with the Worthington Pump & Machinery Corporation.

The Babcock and Wilcox Company has established marine storerooms in Baltimore, Norfolk, New Orleans and San Francisco, through which proper material for B. & W. boilers may be obtained. In addition, they are establishing a marine storeroom in New York City, which will be stocked with spare and replace parts and tools. Orders placed in New York will be received at the company's office, 85 Liberty Street. For the convenience of its customers, the company has arranged a catalogue listing the various materials which may be required in connection with the operation of their boilers and may be obtained through the New York office or any of the storerooms.

TRADE PUBLICATIONS

Refractory Products.—The October bulletin of Laclede-Christy, St. Louis, Mo., contains articles on the value of clay products in the United States. The use of firebrick in glass plants, electric furnaces, metallurgical furnaces and the like.

Anti-Slip Tile.—A catalogue describing in detail a new non-slip tile for walking surfaces which is manufactured by the Carborundum Company, Niagara Falls, N. Y., is being sent out by the sales representatives, The American Abrasive Metals Company, New York.

"The Valve World."—The October issue of the Crane Company, Chicago, bulletin contains several excellent business and economic editorials and a special feature article of the City of Pittsburgh, its industries and buildings, with special reference to Crane service in this district.

Jahncke Dry Docks.—A pamphlet containing photographs and a description of the plant and operation of the dry docking facilities of the Jahncke Dry Docks, Inc., New Orleans, La., has been published by this company. Statistics are also given of the importance of New Orleans as a shipping port.

Diesel Engine Statistics.—A pamphlet containing diagrams compiled from "Lloyd's Daily Index" indicating the extent to which Burmeister and Wain Diesel engines are used in marine installations in direct comparison with the other types of marine Diesel engines has been sent out by Burmeister and Wain, Copenhagen, Denmark.

Marine Diesel Engines.—A complete illustrated catalogue of Werkspoor marine Diesel engines has been sent out by Werkspoor, Amsterdam, Holland. Details of the construction are given with special reference to unusual features of these engines. A special section is devoted to a description of the reversible propeller. A table of the standard size engines manufactured is also included.

Oil Coolers.—The multi-whirl oil cooler and the heat exchanger produced by the Griscom-Russell Company, New York, are illustrated and described in Bulletin 910 recently sent out by this company. Among other purposes, these types of equipment are designed for cooling oil in turbines, transformers and the like. Special reference is made to the use of this equipment in oil refining service.

Modern Floors.—A booklet intended to show the trend of modern practice in regard to flooring used in the construction of large buildings and the reasons for the success of present-day flooring methods is being distributed by the Marine Decking and Supply Company, Philadelphia, Pa. Details of the use of Lit-O-Sil-O flooring in various types of service with illustrations are given with a special section devoted to the use of this flooring aboard ship.

Malleable Nickel.—A resume of the properties and uses of pure malleable nickel is contained in Bulletin 101 issued by the American Nickel Corporation, Clearfield, Pa. The data are to a great extent tabulated and include the forms in which "American" nickel is produced, the purpose for which it is best adapted, its chemical and physical properties, the melting points of various metals, their specific gravities, standard gages for metal sheets and wire and other useful information.

Boiler Settings and Chimneys.—A bulletin outlining the service of Ballard, Sprague and Company, Inc., New York, in the construction of boiler settings, chimneys, steel stacks, and the like, has been issued for the benefit of those interested in boiler plant and industrial power plant construction and repair. Details of interesting stack construction jobs with numerous photographs, as well as boiler settings, acid towers and other types of construction are featured.

WE GUARANTEE that of this issue, 5,050 copies were printed; that of these copies 3,779 were mailed to regular paid subscribers, 219 were provided for counter and news company sales, 200 were mailed to advertisers, 74 were mailed to employees and correspondents and 778 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 66,400—an average of 5,533 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The President's Message

THE pending shipping legislation has been considered of enough importance to the general welfare of the country to warrant calling Congress together in extraordinary session and the President, himself, has delivered a special message to that body outlining our shipping position as a problem of "grim actuality." As the President said, "We are facing insistent conditions, out of which will come either additional and staggering Government losses and national impotence on the seas, or else the unfurling of the flag on a great American merchant marine commensurable with our commercial importance to serve as a carrier of our cargoes in peace and to meet the necessities of our defense in war."

Although written in stirring language, this is indeed a practical statement and the whole message, in fact, is presented in a plain yet forceful way which should appeal more to our business faculties than to our sentimental aspirations. "Our immediate problem," declared the President, "is not to build and support a merchant marine, which I hold to be one of the highest and most worthy aspirations of any great people: our problem is to deal with what we now possess. Our problem is to relieve the public treasury of the drain it is already meeting."

Passing over the wartime cost of over $3,000,000,000 that we spent on these ships, the lives and treasure that were lost because of our impotency on the sea and the average monthly deficit of $16,000,000 that the Government suffered until the Shipping Board secured experienced operators, the President pointed out that the merchant marine, two-thirds of which is idle, still costs us $50,000,000 a year. "It is not, therefore, a question of adding new treasury burdens to maintain our shipping," he declared. "We are paying these burdens now. It is not a question of contracting an outlay to support our merchant shipping, because we are paying already. I am not asking your authorization of a new and added draft on the public treasury. I am appealing for a program to diminish the burden we are already bearing."

And the worst of it is that this annual expenditure of $50,000,000 is not getting us anywhere. On the contrary, it is an effective barrier against a permanent merchant marine under private ownership, for capital does not dare to enter into competition with Government-owned ships which, if the fixed charges, such as interest, depreciation and insurance, are taken into consideration, are costing us much more than fifty million dollars a year.

Depreciation, however, is constantly at work and it is this factor that makes it imperative to transfer the fleet to private ownership at the earliest possible moment. Many vessels are worthless now; all are deteriorating and under present conditions it is only a question of how long before it will be necessary for the United States, which 70 years ago had a merchant marine that was second to none, to acknowledge to the world that we cannot operate on the seas.

The President indicated three possible courses of action as follows:

"The first is constructive—enact the pending bill, under which I firmly believe an American merchant marine, privately owned and privately operated, but serving all the people and always available to the Government in any emergency, may be established and maintained. The second is obstructive—continue Government operation and attending Government losses and discourage private enterprise by Government competition, under which losses are met by the public treasury, and witness the continued loss and deterioration until the colossal failure ends in sheer exhaustion. The third is destructive—involved the sacrifice of our ships abroad or the scrapping of them at home, the surrender of our aspirations, and the confession of our impotence to the world in general, and our humiliation before the competing world in particular."

A choice among the three must be made and the President believes that the people demand the constructive alternative and that Congress will no longer sustain a program of ob-

struction. Subsidy, to many, is an offensive term, but the Government has aided other industries and the establishment of a merchant marine will be a means of benefiting the whole country. "If Government aid is a fair term," he said, "—and I think it is—to apply to authorizations aggregating $75,000,000 to promote good roads for market highways, it is equally fit to be applied to the establishment and maintenance of American market highways on the salted seas. If 'Government aid' is the proper designation for forty to fifty millions annually expended to improve and maintain inland waterways in aid of commerce, it is a proper designation for a needed assistance to establish and maintain ocean highways where there is actual commerce to be carried."

The fact remains that if it is called a subsidy then the fifty millions that we are now expending annually is also a

An Insistent Call

—McCay in the *New York American*

subsidy. Under the pending legislation this expenditure would be cut approximately in half and there would be every opportunity to establish a merchant marine. No one can take advantage of the Government under the proposed bill because it provides that after 10 percent has been realized on the actual investment as determined by Government audit one half of all profits above that figure must be returned to the Treasury until the full subsidy has been returned. It is believed that when American genius has had an opportunity to establish itself in this business success will attend and that the outlay will be returned.

Other nations are naturally concerned about our shipping policy and it may be safely said that all maritime countries are opposed to this shipping measure. As Commissioner Plummer recently said, "It is under the best apple tree that you will find the most clubs," and considering that every ton of shipping that we put into commission is bound to displace a ton of foreign shipping, it is no wonder that other nations are concerned. Foreign shipping countries have a right to feel as they do, but what can be said of Americans upon whom the costly lessons of the great war have made no impression and who oppose an Act upon which the very life of the nation may depend.

There are still far too many who declare that in spite of the records of the last sixty years shipping can get along without Government assistance. They should heed the President's statement, that the head of a steamship company operating a fleet of ships had recently called at the executive offices to ask permission to transfer his vessels to a foreign flag. The reason given was that he could reduce his labor costs alone sufficient to provide a profit on the capital invested. Congress has also made shipping laws, to say nothing of applying prohibition to American ships, that are in need of immediate revision. To quote Chairman Lasker, our Attorney General Daugherty has outdone Moses as a law giver for the best that Moses could do was to make the Red Sea dry.

The proper American viewpoint according to the President is "from which one sees American carriers at sea, the dependence of American reliance in the event of war. Some of the costly lessons of war must be learned again and again. But our shipping lesson in the world war was much too costly to be effaced from this or the future generations.

"When people fail in the national viewpoint and live in the confines of community selfishness or narrowness, the sun of this republic will have passed its meridian, and our larger aspirations will shiver in the approaching twilight.

"But let us momentarily put aside the aspiring and inspiring viewpoint. The blunt indisputable fact of the loss of fifty million a year under Government operation remains; likewise the fast diminishing capital account, the enormous war expenditure to which we were forced because we had not fittingly encouraged and builded as our commerce expanded in peace. Here are the facts to deal with; not fancies wrought out of our political and economic disputes. The abolishment of the annual loss and the best salvage of the capital account are of concern to all the people.

"It is my firm belief that the combined savings of operations, losses and the protection of the capital account through more advantageous sales of our war-built and war-seized ships, because of the favorable policy which the pending bill will establish, will more than pay every dollar in Government aid for 25 years."

The New York *Tribune* calls the President's message "An Unanswerable Plea." It says, "Mr. Harding was at his clearest and best in his plea for the shipping bill. That fairness which is one of his most admirable qualities spoke throughout his argument. He presented the unquestioned facts of the situation and set forth the only possible courses of action. In reaching a decision he urged Congress to forget groups and parties and to solve the problem with an eye single to the welfare of the whole country."

Indeed, the President has made a plea that cannot be answered just the same as he has given us a plan to establish a merchant marine for which the opponents of the proposed shipping legislation can suggest no alternative. This plan is based on the facts and findings of the most expert maritime committees that could be gotten together. They were com-

posed of both Democrats and Republicans but no question of partisanship entered into their work. The House Committee on Merchant Marine and Fisheries has favorably reported and endorsed the subsidy bill. The President has spoken and now Congress, sitting in extraordinary session, must decide whether our trade will follow our flag to every port in the world or whether it will take such consideration as our maritime rivals feel disposed to give it.

Standardization

TOO much stress cannot be given to the importance of the informal conference on the subject of standardizing shipbuilding and ship operating practices and equipment held at the Grand Central Palace, New York, during "American Marine Week." From the discussion it was clear that only a well-defined plan of procedure is necessary to insure the co-operation of every organization in the marine field.

The next step, that of conforming with the resolution directing the formation of a committee on plan and scope and ways and means, should be taken with the least possible delay; but great care should be used in selecting the personnel that each phase of shipbuilding and ship operation be represented by men well qualified to act and that the Army, Navy and Shipping Board be included. The fact that the Department of Commerce, which was responsible for bringing about the conference, has pledged its support will go a long way toward insuring success to the movement.

The Star of Phœnicia

"BY night the richly freighted ships of the Phœnicians, skilled commanders of the commerce of the Ancient World, were guided into all the then known ports of men by the North Star.

"More than 3,000 years ago, the emulating Greeks, discovering the valued commercial purposes to which it was being put by these far famed builders of Tyre and Sidon, called it the 'Star of Phœnicia.' "

With this introduction, Mr. Edward A. Biggs, general counsel and vice-president of the Foreign Trade Division, Mississippi Valley Association, has written a brief outline of the history of world commerce entitled "The Star of Phœnicia." In this work he has proved, if the past is any criterion upon which the future may be known, that no country may expect to retain its place among the leaders of nations unless it develops and retains a profitable foreign trade.

It must be noted, however, that although Phœnicia, Greece, Carthage and even Germany acquired wealth and strength through foreign trade, this very trade has been the direct and indirect causes of the wars which resulted in their downfall. But America, unlike the countries of the Old World, is not open to the invasion of armies except they be transported over the sea. So our problem for insuring our safety and prosperity is simple in comparison. If we decide to go after the proportion of world commerce that we are really entitled to, that trade can be amply protected by an adequate merchant marine, that will guarantee safe and regular deliveries, and by a Navy second to that of no other country.

Mr. Biggs points out that "the Mississippi Valley is the granary of this nation as the valley of the Nile was the granary of Rome." It may be added that the surplus products of the manufacturing industry as well as agriculture in that section of the country amount to billions of dollars annually (foreign exports from the Mississippi Valley in 1920 amounted to $5,543,000,000). It ought therefore to be evident, if foreign trade is developed to take care of capacity production in the Middle West, that even if American ships carried every ton of exports and imports from one section of the seaboard, the Mississippi Valley would be the far larger gainer than the seaports through which their business flowed. And with the development of the internal waterways which this section of the country, having a majority representation in Congress, is bound to demand and obtain, and with the migration of seaboard industries which are now a thousand or more miles away from their raw products to the Middle West, which has been freely prophesied, the statesmen of the Valley would be blind indeed to their own interests if they allowed an annual expenditure of a few million dollars to stand in the way of an American merchant marine, the only vehicle that can guarantee the delivery of their products.

That they will not be so foolish is plainly shown by the passage of three Acts in the past few years which are solely designed to build up foreign trade. We refer to the Webb-Pomerene Act which provides that combinations for export trade which could not be formed under the Sherman Anti-Trust and Clayton Laws may engage in the export trade. Second, the Edge Law which provides the means of financing foreign trade. Third, the Merchant Marine Act of 1920 in which the country went on record as favoring any action that might be necessary to provide an adequate merchant marine.

Furthermore, as Mr. Biggs says, every man, woman and child in the United States is financially interested in our Government-owned merchant marine to the tune of $40 per capita. It is barely possible that through antipathy they might allow a fleet, that it cost $4,000,000,000 to construct, to be scrapped if it meant only the ships. But if these vessels are scrapped, it means that the machinery, equipment, etc., in other words the billions of dollars that we have put into added capacity for production for foreign consumption since 1914, must also be scrapped.

Annual Index Will Be Supplied on Request

THE annual index of MARINE ENGINEERING AND SHIPPING AGE will be published separately from the magazine at the end of the year. As the annual index will be useful only to those subscribers who have kept a complete file of the magazine for the year, only a sufficient number of copies will be printed to fill the orders received for it at this office on or before January 1. A copy of the index will be mailed without cost to each subscriber whose order for it is received on or before that date.

If the Shipping Bill Fails—What Then?

The Life of an Industry That We Must Depend Upon for Prosperity in Peace and Safety in War Is at Stake

By "Old Scotch"

EVERY good general before going into a fight makes plans for the possibility of a retreat. It makes no difference how confident he may be of victory, he always plans for contingencies which may arise despite his confidence and his well worked out problem of how to succeed. The better general he is, the more he thinks of what might happen if everything goes wrong. This looking ahead does not detract in the least from his chances of winning.

The advocates of the so-called subsidy bill are just now in the position where they should look ahead, and consider what would happen if the bill should fail. It will not hurt the chances of its passage, but on the contrary it may do some good, if we consider what we will then be facing, and consider it in such a way that we look the situation squarely in the face, and do not deceive ourselves regarding the cold facts which may then confront us.

The record of the past is the best harbinger of the future. If this proposed legislation should fail, we would be no better off now so far as governmental assistance is concerned than we were in the pre-war years, when our total merchant marine engaged in the foreign trade had dwindled to six or eight combined freight and passenger ships. As a matter of fact we will be worse off, because at that time world trade was in normal condition, with no cogs missing from the great wheel of producing commercial nations. If in pre-war years we could only keep these six or eight vessels going, what can be expected now when the ocean carrying trade is "shot to pieces" by the greatest period of depression on the seas the modern world has yet encountered?

Our Overseas Shipping

By means of the appropriation of fifty millions of dollars annually the Shipping Board has some four hundred vessels in operation in the foreign trade, which are carrying about one-third of our total exports and imports. They are extending our trade on various routes, protecting our shippers and importers from excessive carrying charges to the world's competitive markets, and incidentally keeping considerable money in circulation in the American repair yards, giving employment to a very respectable number of American officers and seamen, and helping other industries which are closely allied to ship operation. If the pending bill is not passed so that these ships can be placed in the hands of private owners, how long will this kind of government operation be kept up at a sure loss to the government?

With the axe of retrenchment being lustily wielded by the members of our national legislature, spurred on in their efforts as they are, by a tax burdened public, is it probable that such appropriations will be much longer continued for the operation of the government owned fleet?

Failure of Shipping Bill Means Government Ownership

If they are continued, the die will then be cast for the much dreaded government ownership and operation of transportation facilities on the sea. While such a procedure will be better than having no merchant marine at all, it must ultimately be doomed to failure, as many similar attempts are and have been in the world's history.

So long as the preclusion of foreign shipping from our coastwise trade is continued, we may be reasonably assured of a small merchant marine, but one that will be totally inadequate to prevent rate discriminations in our foreign trade, and to provide the absolutely essential merchant ship tonnage for our national defense. When we were drawn into the recent World War, it was pitiable to behold our helplessness for furnishing anything like the tonnage we needed for troop and supply transport to the European battlefields. Fortunately for us our allies were as deeply concerned as ourselves in getting our troops and munitions to the other side, and quite readily furnished us their ships, for which we paid and paid dearly. The bills for hiring foreign vessels for only a period of six months at the height of the war would have paid for the entire amount of the proposed subsidy to our own ships. Oh! if we could but remember some of our bitter experiences during that period of strife and learn some lessons from them. We never again should hypnotize ourselves into the belief that our coastwise tonnage would supply our needs for merchant shipping when we are faced with the inexorable demands of war.

What Would Become of Our Shipyards?

Let us look at our shipbuilding facilities in case this subsidy bill should fail. Even in these days of depression we still have a sufficient number of shipyards in operation to supply our needs for both commerce and national defense. The paltry contracts they now have in hand have been taken at ruinous rates, with the almost despairing desire of keeping their organizations together. All thoughts of earning overhead expenses and making any profits whatever have been abandoned at the present time. Hope of the passage of the subsidy bill is the only incentive the shipyards have for holding on.

In pre-war years there was sufficient naval work for the Government, handed out at ofttimes ruinous competition to keep a half dozen first-class shipyards busy, in combination with such small orders as they received for coastwise and harbor craft. The naval holiday has removed this sustaining part of their business for at least the next ten years.

Any one at all familiar with American shipyards, must and does know, that two such yards as the Newport News and New York Shipbuilding Company's plants could easily supply all the demands for new coastwise and harbor craft, working each at two-thirds capacity. What would become of the other yards now struggling to keep their heads above water? What would become of the thousands of skilled mechanics, and trained technical staffs connected with our shipyards, if they must depend on the meager amount of work necessary to keep up our coastwise and harbor craft demands for replacements?

Future of Our Repair Yards in the Balance

We have built up one of the most efficient systems of repair plants in this country, during the past five years, that can be found anywhere on the globe. If this subsidy bill fails, and we have no ships of our own in the foreign trade, what will become of them? It is true that shipping will always be coming to our ports, but foreign ships will never repair in American yards on account of the higher costs, due to our higher rates of wages. Such emergency repairs as foreign ships would have to make in American ports, in order that they may resume their voyages to home ports,

would not support one-tenth of the number of men now actually employed in American repair plants.

These repair plants are located everywhere that ships congregate and, unlike shipbuilding plants, are not confined to localities dictated by economic conditions. Thus we have important repair plants at Boston, New York, Philadelphia, Camden, Wilmington, Baltimore, Norfolk, Newport News, Charleston, Savannah, Tampa, Mobile, New Orleans, Galveston, Los Angeles, San Francisco, Portland and Seattle. Let the senators and congressmen representing states containing these shipbuilding and repair plants take heed that, if this vitally necessary legislation fails of enactment, their own communities will be very much affected, when the United States fails to maintain ships of its own in our foreign trade.

The ramifications of shipbuilding and ship repairs are so embracing that but few, if any, of our states will not be affected by the decline of this industry. Iron, steel, copper, lead, zinc, lumber of all kinds, cotton fabrics, rubber, hemp, cordage, coal, oil, paints, hardware, crockery and hundreds of other items enter into the construction and repair of ships. The thousands of mechanics employed must be clothed and fed, so that the raisers of cattle and food products of all kinds throughout the land are also very vitally interested.

The failure to pass this subsidy measure at this time means the practical destruction of shipbuilding and ship repairing in this country for the reasons hereinbefore pointed out. It has been a basic industry ever since the foundation of the country. Never before in our history has its very existence been so alarmingly threatened as it is at the present time, due to the peculiar conditions thrust upon us as an aftermath of the great war. No other industry is so important for our national safety in peace and war as is the art of shipbuilding. We cannot build ships when the art has been lost, nor can we buy them from abroad when war is threatened or at hand. Dives in the torments of the Inferno could place no greater value on water, than we would place on ships after, by our own negligence, we had lost the facilities to build them. The period when we allow our shipyards to close, for want of support, will mark our decadence as a virile nation.

The writer is firmly convinced that this session of Congress will see the enactment of the pending subsidy bill, as he has faith in the common sense of Congress, but it does no harm to consider, as has been briefly done herein, the dire results of its failure.

Maritime History Made at Brussels Conference

World-Wide Acceptance of Uniform Rules That Have Been Dominating Issues of Maritime Law Practically Certain

It is a pleasure to be in position to present our readers with the first official information to reach the United States as to the results of the history-making conferences on the unification of maritime law held at London and Brussels in October. The protocol is in French and was not received by Washington for translation before the first of December. The importance of the deliberations may be judged from the fact that twenty-four nations were represented at the Brussels Diplomatic Conference, and that agreed conclusions were reached on three of the four subjects discussed, and an initial agreement on the fourth. All that now remains in order to secure a world-wide uniform acceptance of the dominating issues of maritime law is for the several Governments to endorse the findings of the Conference—an eventuality that is practically certain.

The Brussels Conference, which was the final and conclusive one, was held on October 17-26, with fifty delegates present. The subjects before it were:

(1) Limitation of Shipowners' Liability.
(2) Maritime Mortgages and Liens.
(3) Contracts of Carriage by Bills of Lading.
(4) Immunity of State-owned Ships.

The agreements were as follows:

Limitations of Shipowners' Liability

Instead of freight and accessories as the measure of liability added to the value of the ship, with the consequent difficulty of investigation and the chances of litigation, the solution arrived at is ten percent of the value of the ship *at the commencement of the voyage.* This ten percent will include some accessories. Thus the freight of the tramp is put on the same proportionate plane as that of the liner. In case of loss of life, the personal liability on the part of the shipowner will be £8 per ton; thus the total measure of liability is fixed at the value of the ship plus ten percent with the provision that in event of loss of life there shall be a separate fund up to £8 per ton for claims in respect of loss of life or personal injuries. This would give life claims in the United States important rights they have never enjoyed, and cargo claims will only be limited by the occasion instead of by the voyage.

Maritime Mortgages and Liens

The only liens having priority over a mortgage are: (1) law costs, taxes, port dues, etc.; (2) wages; (3) salvage; and (4) collision and negligence claims. Masters' disbursements and bills of lading claims are both postponed to the mortgage. In order to prevent injustice to the postponed lien creditor an article was added that notice of the mortgage should be inserted by the official responsible on the ship's papers; and conversely a provision was inserted that in regard to liens for masters' disbursements and bills of lading, claims should only take precedence of the subsequent mortgage, if notice of the lien be given to the registrar of mortgages within three months.

Contracts of Carriage by Bills of Lading

This is the new title for what has been familiarly known as "The Hague Rules." They have been so frequently discussed in Marine Engineering and Shipping Age as to be generally understood in the form in which they came up before the Brussels Conference. That form passed practically unaltered, with two important exceptions. Article III, Rule 6, limits the time to one year instead of two, after delivery of goods or the date when goods should have been delivered, in which the carrier and the ship shall be discharged from all liability in respect of loss or damage unless suit has been brought. The limitations thus prescribed shall not be applicable, if the condition of the merchandise has been contradictorily agreed upon at the time of its receipt. Notice of loss or damage may be given at the port of discharge to the carrier or his agent at the time of the removal of the goods into the custody of the person entitled to delivery, if such loss or damage is apparent; if loss or damage be not apparent at the time of delivery, three days extra are allowed for notice. The phrase "prima facie," so familiar to Anglo-Saxon legal procedure, was vigorously opposed by

the French delegates, and in its stead was employed a more verbose expression which means exactly the same thing.

Article IV, Rule 4, which has to do with deviations, was completely changed. It was finally agreed upon in the following terms: Any deviation in saving or attempting to save life or property at sea, or any reasonable deviation shall not be deemed to be a breach of this convention or of the contract of carriage, and the carrier shall not be liable for any loss or damage resulting therefrom.

Immunity of State-owned Ships

This is the subject upon which complete agreement could not be obtained at the moment, because, although a resolution on the subject had been unanimously passed at the London Conference of the Comité Maritime International the week before the Brussels Diplomatic Conference met, time was wanting to bring the matter officially to the notice of the various Governments, and the consequence was that the delegates came to Brussels without the necessary instructions that would permit of their signing. It will, therefore, have to wait upon future action.

However, a substantial basis for action lies in the resolution adopted at the London Conference and which reads as follows:

(1) Sovereign States in regard to ships owned or operated by them and cargoes owned by them and cargoes and passengers carried on such ships ought to accept all liabilities to the same extent as a private owner;

(2) Except in the case of the ships and cargoes mentioned in paragraph 3 such liabilities should be enforceable by the tribunals having jurisdiction over and by the procedure applicable to a privately-owned ship or cargo or the owner thereof;

(3) In the case of:

(a) Ships of war;

(b) Either vessels owned or operated by the Sovereign States and employed only in Government non-commercial work;

(c) State-owned cargo carried only for the purpose of Government non-commercial work on ships owned or operated by the Sovereign State.

Such liabilities should be enforceable by the like tribunals, but only of the State by which the ship is owned or operated, and should be enforceable by action "in person" as against such State, and in addition by any other form of procedure permitted by the law of such State.

The Value of Tramp Steamers to a Merchant Marine*

Wonderful Success of British Marine Is Due to Her Pluck, Vision and Determination in Building and Operating Tramp Steamers Reaching Out to All Ports of World

By C. H. Potter†

There exist today four distinctive types of steam vessels; first, the combination passenger, mail and express type; second, the general cargo type, trading between United States and foreign ports maintaining definite sailing schedules; third, the tank type, employed in carrying oil in bulk; and fourth, a type known in the shipping trade as the "tramp." The tramp type differs from the cargo liner in that it does not maintain regular sailing dates. Its function is principally to carry bulk cargoes such as coal, ore, grain, lumber, phosphate rock, sulphur, etc. It serves as a medium for relieving freight congestions, and in the past has been the medium whereby many regular berth operations have been established and maintained.

For years prior to the war in 1914 we had no merchant marine employed in foreign trade that was worthy of being called a merchant marine. A few lines were fighting for their very existence under the American flag running between American and foreign ports, but it was hopeless without adequate financial assistance from our Government as an offset against the low operating and capital costs of the competing foreigner. True, we had and still have a splendid coastwise fleet, but I am discussing at this time foreign trade.

For years, statesmen and others who were in close touch with foreign and domestic affairs warned us that a merchant marine was essential to our very being; that our shipyards should be built up; that no nation could continue to be great that did not possess and maintain a real merchant marine, and yet in the face of these repeated warnings we drifted along, doing nothing that was constructive. Congress enacted laws that put added burdens on shipping, increased the cost of operation, destroyed initiative and made it difficult to induce capital to tie up with the shipping industry.

Government Policy Has Changed

To further illustrate and emphasize the weakness of our merchant marine prior to the war, you will recall when President Roosevelt ordered our fleet of battleships around the world it was necessary to employ foreign steamers to carry coal and other supplies for the fleet. This concrete example of our weakness should have inspired us as a nation to support a merchant marine, but we drifted along, little realizing that a day of reckoning was ahead. Again, it was no unusual occurrence for the Navy Department to charter foreign flag steamers to carry coal to the various naval stations in the Pacific, to Cuba and the Panama Canal, for the reason that the foreign steamer carried it cheaper than the American. Surely this was a destructive rather than a constructive method of building up a merchant marine. Happily, however, the Government's attitude has changed, and I am glad to state that it is doing everything possible to employ and encourage its merchant marine.

Possibly we can profit by reviewing what other successful maritime nations have accomplished in the building and developing of their tramp steamer tonnage. England, for instance, is a living example.

The wonderful success of the British marine is due to her pluck, vision and determination in building and operating tramp steamers reaching out to all parts of the world, opening up trading posts, establishing and maintaining other avenues of communication. Not only do they carry merchandise to and from British and Colonial ports, but to and from ports of other nations, our own included. And what is true of England is true of other foreign nations,

*Address delivered at Marine Exposition, New York, November 11, 1922.
†President, Maritime Association of the Port of New York.

especially Norway and Japan. They have made wonderful progress. England's tramp tonnage, I am told, represents 60 percent of its total merchant fleet.

During the war we constructed some fourteen hundred steel steamers—a great and mighty fleet of various types built in American shipyards by American citizens. The bulk of these steamers are at present tied up in our various seaports. Many of these steamers are suitable and available for tramp service, dependent, of course, upon their ability to operate as cheaply as foreigners, which at present cannot be done for the very good reason that the capital cost and our standard of wages and living will not permit it.

Widely Distributed Ownership Desirable

Another factor which has contributed toward the development and success of foreign tramp tonnage is due to the distribution of ownership among the masses rather than among a few corporations. The effect of this distribution of ownership tends to create interest and enthusiasm for the merchant marines of their respective countries.

Congress has appropriated vast sums of money to carry out the provisions of the Jones Bill; through the Shipping Board it has encouraged and developed the passenger liner and cargo liner, and rightly so—but tramp operation has received no support nor encouragement. Figures which I have in my possession substantiate this statement. Since January 1, 1922, there cleared from our United States ports one thousand and three foreign tramp steamers with bulk cargoes and only two hundred and twenty privately owned American steamers with bulk cargoes.

Senator Wesley L. Jones, in giving his views in regard to the tramp steamer, states "that, while the Merchant Marine Act of 1920 does not specifically refer to this particular type of vessel, it should be taken for granted that tramp steamers would be one of the main parts of any adequate merchant marine, and notwithstanding that the Shipping Board is directed in respect to shipping routes and steamship lines, there is no warrant for the board's concluding that tramp steamers are not an integral part of an adequate merchant marine."

Therefore, it is fair to assume that it was not in the minds of the framers of the Jones Bill that private companies could operate and compete with foreign steamers without receiving financial assistance in some form from the Government. Comparative figures disclose that it costs 25 to 30 percent more to operate an American tramp steamer than it costs a foreign steamer of like tonnage. This fact alone should be convincing proof that a subsidy is necessary for the development and maintenance of our merchant marine.

Same Principle Applies to Foreign as to Coastwise Trade

I hear some say, why worry about it? If foreign steamers will carry our imports and exports cheaper than American steamers, let them carry it. Then, why not go further and apply that same principle to our coastwise trade? For example, take one particular branch of our coastwise trade—I refer to our intercoastal trade. Today we have about 80 of the finest cargo steamers afloat averaging ten thousand deadweight tons, carrying general cargoes between Atlantic and Pacific coast ports via the Panama Canal, giving employment to a large number of officers and men. Again, why not continue to have foreign colliers and supply vessels trail our battleships and carry coal and oil to our naval stations? That has been done, and in peace times. Put these questions to our citizens and I venture their reply would be almost unanimous in favor of protecting our coastwise trade and against employing foreign ships to carry coal and other supplies to our naval stations. This service should be performed by our tramp steamers.

The point I wish to emphasize is that this protection to our coastwise fleet is in reality a form of subsidy—transportation of Naval coal and supplies in American vessels costs more than a like service in foreign bottoms and therefore takes the form of a subsidy.

It is gratifying that the present proposed subsidy bill provides for compensation to the tramp type of steamer—and to my mind the subsidy bill, if enacted, will revolutionize our merchant marine.

Shipping at Critical Period

Without national aid our merchant marine cannot exist. We are at a critical period, and it now rests with Congress as to whether or not we shall have a merchant marine worthy of this great nation.

In case of war we need large fast steamers for scout ships and for carrying troops. We need cargo liners and tramp steamers to carry supplies for the Navy and base supplies—in both instances they are indispensable—and more, in peace times we need all types—passenger and freight, fast and slow—for the proper development of our world trade. We don't ask for it all, and never did, but we have the right and should demand our fair share.

My hope is that Congress will adopt a subsidy bill that will make possible the development of a merchant marine suitable for national defense in case of war, and, in times of peace, to develop and maintain avenues of trade. Also, that Congress will revise our navigation laws insofar as they tend to obstruct and destroy the healthy growth of our merchant marine.

To sum up—the tramp steamer is valuable and essential:

(a) as an auxiliary aid for national defense purposes
(b) as a medium for the development of our Naval Reserve
(c) to transport coal and other supplies to naval stations and naval vessels
(d) as a merchant vessel to transport bulk cargoes
(e) for relief expedition purposes
(f) for relieving freight congestions
(g) as a pioneer for establishing a regular berth service
(h) as a medium to prevent profiteering

With adequate financial Government aid spread over a term of years or until the merchant marine can be stabilized and made self-supporting, plus American genius, initiative and perseverance, unhampered by Government red tape and wastefulness, I make bold a prophesy that we as a nation will witness the dawn of a new era in our shipping industry, and that in due time we shall have builded on the foundation already laid, a permanent merchant marine worthy of this great and glorious nation.

Simplified Practice as a Service to American Shipping

Address Delivered at Informal Conference on Standardization of Shipbuilding Equipment at Marine Exposition, New York, on November 10

By Ray M. Hudson*

YOUR chairman has stated the purpose of this conference. Let me supplement his remarks by saying there is nothing in which I have to offer as Secretary Hoover's representative that suggests government interference, restriction, regulation or control. You all know the Secretary is a firm believer in "less Government in business and more business in Government." Mr. Hoover's major interest in this meeting (made possible through the good offices of Colonel Simmons of the American Marine Association of which he is president) is along the line of waste elimination and it is entirely from that angle that I will present this message from my Chief regarding "Standardization, and its possibilities for greater usefulness to the marine field."

A few weeks ago during a trip along the Philadelphia waterfront, I saw eight warships, and one hundred and twenty destroyers, and other fighting craft tied up in the basin of the League Island Navy Yard. A little farther along, at Hog Island, I saw nearly one hundred and fifty cargo carriers, anchored row upon row. The contrast between that scene, and the one I saw at the same place four years ago, is a fit subject for a master in the art of graphic description. But being an engineer, instead of a novelist, or an artist, I could only make inward comment on the great change occurring in so short a time in the economic conditions of our country. Since a similar picture is possible in several of our harbors, the coincident idleness of both those great fleets is—or, at least, should be—a matter of deep concern to every business man in America, for in their present state, they represent a huge, economic waste—a waste that is not measured in terms of depreciation and interest on the tremendous investment represented—but instead is measured in the ever-increasing loss of the useful service they might well be performing in the promotion of trade, industry and transportation of these United States! The crudest evaluation of that staggering loss should challenge us all to a degree of concerted action in behalf of the American merchant marine!

This great annual Marine Exposition, which we are privileged to attend, is a splendidly organized piece of publicity, which will accomplish much toward arousing the American public, not only to a better appreciation of the magnitude of the shipping industry, but more than that—to a better understanding of the vital importance of a successful merchant marine as a factor in the future growth and prosperity of America. But with all due credit for this mighty effort, which recognizes that "well-begun is half-done," there is yet a vast amount of work to be done within the industry itself, before the people will believe that the returns on the investment will warrant their cooperation and support!

For example, what opportunity is there within the industry for further refinement of ocean transportation? Are there any avoidable wastes in current construction, operation and maintenance practices? If so, to what extent do they exist, and what would be the effect of their elimination on present costs? Are we now making full use of the best thought and experience within the industry? Is it possible to simplify methods both commercial and engineering beyond their present status and, if so, would the results justify the effort from a dollars and cents standpoint?

Unless the shipping industry is totally unlike our many other industries, there is in it, as in the others, a real need for rigid self-analysis and a careful determination of all existing uneconomical practices which add cost but which do *not* increase the volume of business done or enhance the quality of the service rendered.

Waste Disclosed in Industries

When Secretary Hoover was president of the American Engineering Council, he directed a survey of waste in industry. Six major industries were carefully studied, and the relative waste, considered in the light of the best practice then existing in the industry, ranged from 28 percent in the metal trades to 64 percent in the men's clothing manufacturing, or say an average of 40 percent of all effort *lost* or spent without a tangible or definite return. As a result of this survey, which might well be called "the Alarm Clock of American Industry," there has developed a widespread community of interest in the general problems of increasing production, securing a more sensible distribution of demand throughout the year, improvement of organization and executive control, and the application of the principle of standardization to products, to materials, to the equipment and also to the performance of the labor by which these are produced!

All of this effort is predicated on the belief that concerted action toward the elimination of waste will lower costs, broaden markets and yet maintain the high standards of American living through providing a fuller measure of this world's goods for the same expenditure we now make.

Purpose of Division of Simplified Practice

The Secretary has organized our Division of Simplified Practice to assist the industries in the solution of their problems of this nature, believing that the facilities, the moral weight and the prestige of the Department of Commerce will facilitate constructive action. It is not our thought, or purpose, to pose as experts in any field; the only experts we know are those we find in the particular field under consideration. Those of you who heard the paper on "Standardization" by Mr. E. H. Riggs, before the Society of Naval Architects and Marine Engineers, had the pleasure of hearing a real expert in the matter. His summary of the standardizations already achieved and practiced within the industry shows both sides of the question in a comprehensive manner. We fully agree with him that the question before us today is *not* one of the intrinsic merits of the principle, but rather a question of the *extent* to which it can be, and will be, applied by you all. In reviewing the membership of the American Marine Association, we find there are many firms who are members of trade associations now carrying on definite simplification programs for the good of the industry they represent. Our Division is participating in the work and can point to simplifications achieved in two major fields—surveys for possible elimination of excessive and unnecessary sizes and varieties going on in sixteen other fields, and contacts with nearly a hundred other industries—that believe that simpli-

*Division of Simplified Practice, Department of Commerce, Washington, D. C.

fied practice offers them advantages and benefits well worth obtaining.

What Simplification Is

Now just what is "Simplification"? Let me state it in Secretary Hoover's own words:

> "It is certain that there are a great many articles of every day use in which the manufacturer would be glad to undertake some cooperation in standardization, from which the saving in national effort would be interpreted, not into *millions,* but into *billions* of dollars! This does not mean that we stamp the individuality out of manufacture, or invention, or decoration—it means basic sizes to common and every day things."

Just think for a moment what would be the result of such a cooperative effort among all the elements of the shipping industry here represented! Suppose that in the many items used in ship construction there existed a much greater degree of standardization than now prevails. Is it not conceivable that construction costs would be lowered considerably? The manufacturers of equipment, parts and fittings would be enabled to work more along the lines of mass-production than the present system of highly *individual,* specialized construction permits. As a consequence, the shipbuilders would have a greater flexibility of supply, a lower purchasing cost and would further benefit through lessened assembling or installation costs, as well as in a shortening of the total period between the final authorization of the plans and the delivery of the completed vessel.

Greater standardization made possible through simplification also means lower maintenance costs, for standardized parts are not only more readily procurable and more quickly interchanged for worn or broken parts but their use means large direct savings and even greater indirect savings, due to the consequent reduction of idleness or "stand-by" charges.

Standardization Reduces Cost of Transportation

Standardization has been, and still is, a very important element in reducing the cost of transportation. Back in 1867, when railroading in America was yet in the early stages of development, a group of far-sighted, practical-minded men formed the Master Car Builders' Association, for the "advancement of knowledge concerning the construction, maintenance and service of railroad cars and parts thereof." Another object of the association was "to provide an organization through which the members, and the companies they represented, could agree upon joint action to bring about uniformity and interchangeability in the parts of railroad cars." Today, the American Railway Association, which absorbed the Master Car Builders' Association, publishes a "Manual of Standards and Recommended Practice" covering: Specifications for Materials, Fundamentals and Details of Car Construction, Inspection and Test Methods, and a long list of other pertinent subjects.

The automotive industry was also quick to appreciate the need and value of standards and today the standard handbook of the Society of Automotive Engineers is used by nearly every draftsman and designer in the industry.

Results of Application to Motor Boat Industry

The motor boat industry has been directing its efforts for some time past toward producing standard boats in large quantities. It is now possible for dealers, and others, in almost any part of the world to secure reliable, well-built, runabouts, cruisers, fishing and work boats, dories and house boats in any desired number, with a wide range of sizes and power plants, at attractive prices and without delay in delivery.

By standardizing its product and the components thereof, the industry has simplified the buying of spare parts and also the installation of different engines in the same size and type of hull. Not only that, but further study is being given to the interchangeability of marine hardware.

Possibilities with Larger Vessels

Is it not logical to assume that there exists similar opportunity for the application of simplified practice in the design, construction and maintenance of the larger vessels? In our correspondence with several of the groups here represented, we have received suggestions on the possibilities of greater standardization in—pipe and valve sizes, fire and deck hose, grate bars, ash ejector pipes, pistons for auxiliaries, stuffing boxes, propellers, anchor chains and dynamo brushes. Each of these items suggests a survey to determine the most commonly used types and sizes thereof, and the elimination of unnecessary varieties.

There are, no doubt, many other items used in building and outfitting, in which the existing variety in size can be greatly reduced with advantage to all concerned.

However, simplified practice applies not only to the mechanical problems, but to the commercial problems as well. For example, there is a general movement among shippers and warehousemen to simplify current commercial practice through standardizing the forms and papers passing between them and the public. The possible economies and advantages of standardized ocean bills of lading have been frequently discussed in the marine trade papers, and it is very probable that their adoption as a simplified practice will lead to similar effort to refine other features of the clerical work involved in handling cargoes, with a resultant saving in operating costs.

The direct costs of loading and of discharging cargoes may be reduced through the standardization of equipment best suited for transferring goods. Savings made in that operation mean reduction of the delay in port, thereby increasing the "turn around" and consequently the earning capacity of the ship. Greater standardization of cargo handling gear means the advantages gained in transportation will not be lost in port.

Simplification an Aid to Foreign Trade

But aside from those direct economies that will come to the shipping industry, if it applies simplification, there is another attractive side to the subject and that is its value as a builder of foreign trade. Many of our manufacturers know that domestic industry has outgrown the domestic markets and that America must seek outlets for her surplus products in foreign countries.

At the recent convention of the American Bankers' Association its commerce and marine commission, in reporting its studies of the merchant marine situation, said:

> "It is well recognized that the United States has reached a point in its industrial and commercial development where increase in foreign trade is essential to the marketing of surplus agricultural products and manufactured goods. If producers were to depend altogether on domestic consumption, it is believed there would be a recurring demoralization of prices, due to over-production. To a considerable extent, therefore, a stabilized prosperity depends upon adequate transportation guaranteed against interruption by carriage under our own flag for the greater part thereof."

Meeting competition in transportation is mainly a matter of continuous reduction in the cost of moving a ton of freight a given number of miles. Eliminating waste through simplifying current practice will help greatly toward that end. Many of our manufacturers are meeting foreign competition by applying standardization and simplification, thereby lowering the cost and improving the qualities of the goods they ship overseas. Our Bureau of Foreign and Domestic Commerce foresees a gradual rebuilding of our export trade and is making every effort to bring the profits from it into every manufacturing center in our country. This cooperation of the Department with industry forecasts the time when there will be a far greater demand for ocean transportation than now exists. As a matter of preparedness against that time, it seems highly desirable that the economic advantages

of simplification to the entire shipping industry be studied and analyzed. Speaking of preparedness—the same committee of bankers, just referred to, further stated that following the disposal of the present government owned fleet, "steps should be taken leading to the building of those types of vessels which our merchant marine now lacks, and which should be built with a view to use as naval auxiliaries in case of war." Standardization should play an important part in any new construction, and now, when things are quiet, is the best time to decide what that part will be.

It savors of ancient history to talk much now about the Great War, but it is only good sense to apply the lessons we learned then to our plans for the future. Those of you, who aided in the hurried building of our ships then, know only too well that the lack of standardization was, at first, a *great obstacle* to rapid construction and a serious factor in the multiplication of costs. Later, it proved to be an essential element in winning the war.

It may interest you to know that the War Department is closely watching the present trend of simplification with regard to its importance in national preparedness. They see in it possibilities for quicker mobilization of requirements, through having available maximum quantities of standardized articles. Such articles, by reason of their relative ease of production, permit greater flexibility of supply, with a minimum disturbance of processes and a minimum displacement of labor.

Foreign Countries Applying Standardization

If there were no other reason for immediately attacking this problem, the activity of foreign countries is sufficient! Eleven European nations are applying standardization—so is Japan, and also Canada. The British are very active in its application to marine problems, the British Engineering Standards Association having published specifications for: Structural steel for shipbuilding; main and auxiliary boilers; steam feed pipes, cocks and valves; condenser tubes; shafting for marine engines; hinges and locks for ship's joinery work; table glass and crockery; oil lamps, and also vertical bollards, or bitts. That body is working on nearly forty other simplifications.

The *London Times* said in a recent editorial, "it seems certain that industrial supremacy in the future will depend very largely on the simplification of manufacturing processes to avoid waste."

Not long ago, the Norwegian Standards Association asked the American Engineering Standards Committee for a summary of the standards developed for American marine construction. Here in America, we ought to have some center of information that will keep us all fully informed on what the other nations are doing toward lessening construction, operation and maintenance costs. Secretary Hoover said recently that, if we are to maintain the industrial and commercial lead which standardization has given us over the other industrial countries, we must carry it much farther than we have.

We are told that American shipping cannot compete with foreign shipping, that certain legislation revision as well as certain financial assistance or cooperation is necessary. Granting the truth in those statements, neither of those measures in themselves will automatically produce lower costs, volume business and faster or better service—which in the last analysis form the real basis of competition in any form of commercial activity. And until every group or association concerned with our merchant marine problem is actively engaged in a united and concerted effort to improve the science and art of ocean transportation, through eliminating all avoidable wastes and simplifying current practice, the industry as a whole will not be living up to its true responsibility and obligation to the American people, from whom and to whom it is looking for support and cooperation! Standardization, simplification—call it what you will—is a potential economic force which we should put to work for us.

Standardization when brought about by producers or consumers alone may cause suspicion as to the motives but when all interested parties, including the Government, cooperate in the project, then there can be no such question. An opportunity for such cooperation is found in the Simplified Practice undertaking sponsored by our Secretary of Commerce.

How Simplified Practice Is Applied

When the principles of Simplified Practice are applied in any field, all interests—producing, distributing and consuming—agree to recognize certain dimensions and varieties, among the tremendous diversity produced, as a standard practice for the ensuing year, or other period, set to the agreement. The remaining sizes and varieties are eliminated by mutual consent as obsolete, unimportant or poor practice. Major production is thus directed to a temporarily standardized line, while the engineers, designers and inventors are left entirely free to develop all possible improvements. At the end of the period covered by the Simplified Practice Recommendation, the industry again convenes and makes such modification in the recognized varieties, as may be necessary to include advances in the art.

In Secretary Hoover's plan, the recommendations adopted are published by the Department of Commerce, which through its Division of Simplified Practice, accumulates data on the percentage of product made or consumed in accordance with these recommendations and on the special varieties which are found necessary. The Division thus gathers information for subsequent conferences, permitting intelligent modification of recommendations.

In certain fields, such as weights and measures, establishment of permanent and absolute standards is obviously not only warranted, but vitally necessary. In industrial and engineering fields, on the other hand, it seems probable that the elementary and flexible simplifications contemplated in the Hoover plan will prove a most valuable modification of the earlier standardization conceptions.

Suggestions Offered

If then you feel that there are some worthwhile gains to be made through this form of waste elimination, I would suggest.

1. That there be formed a Central Committee, or "American Marine Council," made up of representatives from every association or group interested in, or connected with, our merchant marine problem.

2. That this council, if you please, be given the responsibility for a comprehensive survey of the facts to determine:

(a) the prevalent wastes in current practice, both commercial and engineering, and

(b) the extent to which simplification and standardization may be practically applied throughout all phases of the industry, and

3. That a definite time be set for the completion of the survey, and for another general meeting to receive the report, and act on its recommendations.

When that time comes, we cordially invite you to hold the meeting at the Department of Commerce in Washington, and to make full use of our services in achieving your objects.

New Radojet Pump.—At the Marine Exposition the C. H. Wheeler Manufacturing Company, Philadelphia, Pa., exhibited a new Radojet pump showing combined inter and after condensers. Heretofore there has been a separate inter condenser condensing the exhaust steam from the first stage of the radojet and a second after condenser condensing the exhaust steam from the second stage of the radojet. These have now been combined into one unit.

Standardization as Affecting American Shipbuilding*

By E. H. Rigg†

During the last two decades there have been many converts to standardization; it has made stronger headway in fields other than shipbuilding, and there is almost no one today who will deny the value of the general principle. It is when you come to apply it to concrete cases that difficulties arise. Without standardization, shipbuilding, as we knew it during the war, would have been impossible; the question is therefore on the extent to which it shall be carried rather than on whether or not standardization shall be adopted.

IN shipbuilding standardization much has been done by such bodies as the Federal Bureau of Standards, the American Bureau of Shipping, the United States Steamboat Inspection Service, the American Society for Testing Materials, the American Engineering Standards Committee, also the Treasury and Navy Departments. The Navy Department is mentioned here last merely because this paper mainly deals with merchant shipping. On navy work, navy standards are naturally paramount, and their influence also extends into merchant work in yards doing both kinds. Owing to the service conditions under which warships operate, these standards are generally more exacting than those governing merchantmen.

Apart from the well-known and long-established classification societies, there is a relatively new body of this nature that bears on our business to a considerable extent, namely, the British Engineering Standards Association, whose work in standardizing specifications for structural materials, products and fittings entering into ship construction is decidedly more far reaching than anything we have; however, as noted above, we are by no means without similar bodies.

Standardization is a large subject. The deeper one gets into it the larger the possibilities, and, as would be expected, the more impressive the difficulties.

A paper on this subject read before the North East Coast Institution of Engineers and Shipbuilders by Mr. C. leMaistre, secretary of the British Engineering Standards Association, in March of this year, is both interesting and informative. One among many interesting points brought out is to the effect that standardization has reduced steel costs of production by at least 5 shillings (nominally $1.25) per ton; such points effectually nailed down as proven will do more than many sermons to convert the skeptical. A study of this paper will well repay those interested and will also show the standing which standardization has already attained in shipbuilding abroad.

An extremely interesting test of the value placed on standards is to ask one of our yards to build a vessel using Whitworth standard screw threads throughout. It looks fairly innocent at first, but wait till you begin writing to the makers of the auxiliary machinery, to say nothing of your own machine shop's feelings in the matter!

Standard Ships

Taking standardized ships first, as distinguished from variegated ships built from standard parts: during the war we built many such standard ships; the Hog Island, Submarine Boat Corporation and Great Lakes numbers and types of standard cargo vessels stand out pre-eminently as the biggest efforts along those lines. There were also other standard cargo types, but these were built in fewer numbers. The vast numbers of submarine chasers are another instance, also the large number of destroyers built for the Navy.

The cargo vessels above referred to were laid down to meet a war need, it is true, but they remain distinct from the strictly naval vessels. As one effective answer to the submarine campaign of the enemy, they, without doubt, fulfilled their object. The 7,825-ton Hog Island boats are a more generally useful type than the Submarine Boat 5,075-tonners or the Great Lakes 4,200-ton steamers, useful as these smaller vessels are in such localities as the Baltic and on the short-run trades.

That we shall again witness such an effort is not probable; further, that this effort has helped to put a quietus on general cargo vessel construction for some time ahead is also to be admitted. As an example of standardized work which justified its conceivers, there is no doubt that it did more than make good; while there were differences in detail in these groups, such minor variations did not alter the status of the ships as standardized products. These detailed differences sometimes indicated progress, but were in many cases unjustifiable and extremely annoying to the builders; they serve to emphasize one of the main arguments against standardization, namely, that it prevents progress. Automobiles are standardized, but that does not prevent improvements being made in the 1922 over the 1921 model. In the same way, succeeding ships for a particular trade can and do embody improvements over the earlier ones.

The situation for standard ships would appear to be as follows: In emergency, when large numbers of ships are wanted in a hurry, by all means build to a standardized design. When all are building in one yard this holds absolutely; when building in several yards it holds in general, with the qualification that each yard should be allowed to adhere to its own general way of doing business and to work to the same general plans and specifications in its own way, with freedom as to details. This can be qualified to say that full consideration should be given to a yard having plans, etc., available for a vessel substantially equivalent to the proposed standard ship.

Main and auxiliary machinery should be common to all ships of the type and therefore interchangeable from ship to ship to a very large extent; this has helped deliveries frequently when a broken part in an earlier ship can be taken from a later vessel.

As a normal proposition, wholesale standardization of complete ships is not to be looked for. It cannot be denied, however, that there are so many tramps of certain deadweights as to very closely approximate standardization. The large class of 7,000 to 8,000 tonners is worth noting, even though we have variety in detail to suit different builders' and owners' ideas.

When repeat orders are given for a vessel already built, the work is thus partly standardized. There are many instances of this on record; a type proves satisfactory in service and may be repeated at intervals in groups as many as fifteen or twenty times, with only minor and detail changes. The work is thus spread over a period of years, so that the advantages due to repetition work in the shops do not enter into the consideration. The main advantage is in time,

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 9, 1922.

†Naval architect, New York Shipbuilding Corporation, Camden, N. J.; member of Council, Society of Naval Architects and Marine Engineers.

because the design, plans, material-orders and specifications are immediately available.

Oil and cargo ships come in the repeat-order category rather than passenger ships. The Shipping Board 535-foot passenger ships were an example of a large number of ships laid down to the same original plans as troopships, but finished up in groups for several lines and services as passenger ships. The hulls were practically identical, but even here changes were made to get different oil-fuel capacities; the machinery was built in groups to spread the work to different boiler, turbine and gear plants, so there was only partial standardization in machinery. The passenger accommodations were most wide of "sameness." While it is misleading to say that no two ships were alike, it is fair to say that with sameness of outline plans we have very considerable differences in detailed arrangements and decorative schemes, so that these differences finally resulted in a fleet wherein there were greater or lesser differences in every ship. Arguing from this and from general experience, standardization of passenger ships may be dismissed from serious consideration, except in quite small groups. Shipbuilding, in the nature of things, does not lend itself to standardization as a whole, but to build large ships in groups of limited numbers, suitable to particular trades, is a practice as old and older than anyone living today.

There is a large field where more has been accomplished than meets the eye on first approaching the subject, namely, international agreements on such matters as rules for avoiding collisions; signal codes; tonnage laws; lifeboats, and subdivision of passenger ships. Working agreements between classification societies in different countries tend toward broad-gage standardization. Standard loadline regulations are well on the way to international scope. Agreement to recognize each other's inspection certificates covering passenger and crew accommodations between countries having substantially the same regulations is another step towards the common goal.

The tendency toward international codes covering the fundamentals of shipping both as to building and to operating is right and proper, particularly when it is remembered that the high seas are world wide and provide highways common to all nations. The sea does not ask if a ship be American or French, but treats them all alike; hence the growing volume of international standardization of fundamentals is to be welcomed and helped as a means of getting along better with international intercourse and trade.

Standardization of Materials

Turning to the standardization of parts entering into ship construction, we find much to study. We also find great progress to record. We even find some progress towards international standardization, though this phase of the problem has naturally not progressed nearly as far as international covenants covering broad principles.

Consider the steel of which ships are nowadays constructed. Wood, iron and concrete need not be considered here, because merchant shipping today is, to all practical intents and purposes, universally constructed of steel or steel products.

International specifications for ship steel have not yet arrived in spite of efforts which were under way when the war broke; the difficulties are great, and they begin in the mines where different ores have different characteristics and properties. A universal specification is difficult to draw that would avoid undue favor to some mills as compared with others. American, British and German steels have their own characteristics, but given a willingness to cooperate, it should not be impracticable to draw specifications broad enough to cover a merchantable article satisfactory for use the world over. One great question is: Can genuine willingness to agree, if possible, be obtained? Without at least that as a basis, it is no use trying for international steel standards.

During the war, considerable progress was made towards international standard rolled sections, such as angles, channels and bulbs; this as between America and Britain. Here we have two standards, structural shapes and ship shapes, these ship shapes being identical with the British except in minor points; there they have one set of standards for bridges, buildings and ships. There is considerable opinion in favor of a single standard here. The manufacturers fear scrapping of equipment before it is worn out; the answer is that properly regulated standardization is not an over-night affair and will involve no scrapping of good equipment. France has been on a metric basis of measurement almost as long as the memory of man runneth, but I am told that even yet in the remote rural districts the old non-metric units are largely used in local trading.

The inch, pound and metric units involve us in trouble when considering international standards. The obvious way to get around it is by printing two columns parallel to each other; customers in metric countries can use the one in which they can think best. The metric system, or lack of it, is no bar to international standards, though it is an admitted difficulty, which benefits the printing trade more than anyone else.

Since the war, progress towards international rolled steel standards is to be noted on the part of Australia, Belgium, and France, as well as between ourselves and Britain. Plain angles present few difficulties; the channels, bulbs, and I-sections are the crux of the matter. Standardization of what we may term secondary ship materials such as brass, bronze, iron and wood is also to be kept in mind.

Again a real question is: How willing are the different parties to go at the matter and find a solution that will give the best sections designable and commercially manufacturable at this date? Without this willingness, we are merely beating the air.

The war has done at least one good thing: It has taught us that undertakings before considered impossible can be put through provided the will to accomplish is there; that men and women of many races can forget petty differences and work together for a common goal. Whether broad-gage sentiments similar to those inspired by the stress of war can also be invoked for peace-time objects is at least open to debate, especially in the present condition of world affairs.

Again, do the foreign trade elements of each nation want uniformity in these matters, or do they want the Tower of Babel?

The transition stage would have its troubles; the present state has its disadvantages. The same solution for steel specifications, both as to composition and dimensions, as has already been applied to such matters as tonnage, safety regulations, etc., would appear to the writer as the proper one, namely, broad-gage standardization on an international basis with equitable leeway to each nation as far as individual peculiarities are concerned, such as extend from mine to finished product.

In developing new countries, is it an advantage or a disadvantage to have similar structures and equipment built to varying specifications, and to whom do the advantages and disadvantages accrue respectively?

It is to be noted that the Department of Commerce, under Mr. Hoover's leadership, is endeavoring to eliminate waste and reduce costs and so to extend the benefits resulting from simplified practices in industry. The machinery that it is proposed to set up will be representative of all interests concerned and will have safeguards to prevent rejection of newer and better ideas as they come along.

Mr. Hoover uses the word "simplification," which is not the same as "standardization," though in many respects the two will be hard to separate. It is well to bear in mind the

differences between the two words; their meanings and applications will converge and diverge as we study our subject in all its ramifications.

The procedure suggested by Mr. Hoover is very much that of the American Society for Testing Materials, where producers and consumers sit down together and agree to agree or disagree on standard specifications for the major materials and their subdivisions.

A study of Mr. leMaistre's paper referred to above will throw an interesting light on what is being done along the lines of standardization and simplification in British shipbuilding and other industries.

A study of the pocket books issued by the different steel manufacturers will impress one with the vast number of special shapes to which steel is rolled; that a gradual reduction in number of special shapes would benefit everyone concerned will hardly be disputed. As existing commercial equipment wears out this becomes at least possible.

Standardized Methods

Regarding standardized methods of production, shipyards are organizations subdivided into many departments or trades. They are not unaware of what is going on in the general industrial world in the way of advanced methods. There are at least two good reasons why the practices of factories, pure and simple, cannot be fully applied; one is the diversity of product as between ship and ship, and the other is diversity of parts entering in to any one ship.

What all efficient yards are doing, particularly since the present depression set in, is to so organize their methods as to adopt for each shop the best that can be worked in. We all have certain routine ways of doing things. In a poor plant the routine runs the plant for a certain or uncertain season; in a good plant the routine is modified and improved conservatively and constantly in such a way as to cut down work, save time and labor, eliminate duplication, and also secure harmony and effective intermeshing of departments.

Too much departmentalization will kill any shipyard. You all know the small-minded departmentalist who cares not what happens to the department on each side of him, just so long as his particular department makes a good showing.

Modern established yards have their own standard ways of handling work; from design to delivery, standard forms and methods are used. These should only be changed conservatively, and after the management is sure that they have all the cards on the table; a change made to suit one noisy departmentalist will almost surely bring trouble and can very easily change a profit into a loss on the completed ship. We also have standard specifications. For yards handling more or less one line of work, this is undoubtedly correct; for yards with a diversified product it is still correct, but cannot be made to work without greater labor in adjustment to particular cases. These specifications should follow in arrangement the yard charge and plan numbering system, so that an index is unnecessary to one familiar with the system, thus saving more time for more people than will be realized. The index should be there for convenience of owners and others not acquainted with the system.

It seems hardly necessary to say that all forms and drawings should be uniform, also all calculations, material-orders and correspondence methods. The responsibilities and limitations of each department should be clearly defined and no point left in the air to fall hapless between two or more parties.

Standard Details and Fittings

We now come to standard details. Each established yard now has its own standards and each owner has his own particular requirements. Each yard wants to use its own standards, which works for a cheaper ship.

The British have decided that there is no good reason why a lot of fittings and equipment cannot be nationally standardized and, having decided so, they are doing it. There is a host of fittings that lend themselves to this treatment, such as manholes, airports, doors, davits, boats, bitts, cleats, chocks, sanitary fittings, winches, windlasses, anchors, chains, steering gears, etc., down to minor fittings such as cups and saucers. Providing the standards are of a good quality and agreed upon by the jointly interested parties, why not eliminate as much special work as we can? This British experiment is well worth noting as we press on our way to the building of ships economically.

With standardized fittings it is easy to see both time and money saved; stocks can be kept fuller without fear of loss.

Standard Machinery

With reference to machinery, we have just arrived at standard specifications for moderate-powered, reciprocating-engined, Scotch-boilered cargo boats. We arrived there, however, in the midst of the modern upheaval in methods of propulsion; the claims of Diesel drives, Diesel-electric drives; electric, hydraulic or mechanical reduction-gear drives, direct-turbine drives, watertube boilers versus cylindrical, also last, but scarcely least, the war.

The standard specifications here referred to are those prepared in Britain with a view to harmonizing classification and governmental requirements for main engines and boilers and giving to builders one set of rules and specifications to work to. What success has attended their practical working is not known to the writer.

The reconciling of classification and governmental requirements where these overlap is something which will save time and money; the application of two or three formulæ to figure out the same dimension involves duplication of effort and, consequently, waste.

Motors for ship propulsion are a modern development. We already find elaborate standardization here for several reasons; with uniform power per cylinder, engines of four, six or eight cylinders are built. Oil engines are complex affairs at the best; the more parts to a given design the lower the already high cost per unit of power can be kept. Further, their manufacture commenced at a period when the benefits of standardization were already realized.

Electricity plays an increasingly important part in the auxiliary installations aboard ships. This industry is already highly standardized. The requirements of land and sea services should be brought as nearly to a common basis as is practicable.

Repairs and Upkeep

The importance of quick turn around in ports needs no emphasis before this body. The advantage of standardization in giving owners and repair plants a reasonably generous stock of spares to draw upon is obvious. With greater standardization in building, especially in machinery, we automatically get advantages in the matter of prompt availability of parts for repairs and renewals, the economy of which speaks for itself. The more general the standards, the fewer and less expensive the spare parts each individual ship will need on board. Certain parts liable to be needed at sea will always have to be carried, but stocks at terminals can be kept lower without danger of delay to the ship.

Standardization is a natural and inevitable corollary of modern industrialism; mechanisms are both more elaborate and more generally used than formerly. A plant in Chicago manufacturing and selling any one or more of many well-known modern mechanisms must consider the ability of its distant customer to keep the machine in condition. What ultimate good is a typewriter, for example which the owner cannot keep in repair; the "throw it away and buy a new one" answer is that of the reckless cub salesman, except after

the machine is worn out or genuinely obsolete. The only proper answer is standardization of machine and of such spares as are most liable to be needed, backed up by the most efficient distributing agencies available.

Uniform Requirements

The codification of governmental requirements for merchant vessels under one set of regulations should be aimed at; at present these are scattered and come under different departments for enforcement.

The reconciliation of the requirements of two or more bodies with concurrent jurisdiction is very important. The most outstanding case is perhaps that of boilers, the United States Steamboat Inspection Service and the classification societies each having their own formulæ. The success which has attended the adoption of the A. S. M. E. Boiler Code for land work needs no emphasis.

That the practical benefits of uniform requirements on an international basis are not lost to sight is evidenced by the recent reports of the committees appointed by the International Shipping Conference last November. These reports mark a step towards agreement on four important questions connected with shipbuilding, namely, life-saving appliances, wireless telegraphy, loadline, and passenger ship subdivision. The absence of United States representatives on these committees is to be noted, the writer feels, with regret.

Uniform standards of strength for ocean-going vessels may well be considered; the proposed international loadline regulations give us a basis. The various classification societies each have their own; in practice they are fairly close to uniformity. The extent to which their rules could with advantage be standardized might well form a subject for future discussion.

Summary

History has shown conclusively that standardization has already greatly benefited mankind; imagine the chaos if each mechanic cut screw threads to suit his own ideas, as was done in the early days. The whole point is that of arriving at well-balanced decisions on how far to go. Excessive standardization makes for lack of progress, while too little tends to restrict production. The right amount means the maximum of comfort and pleasure in life for the minimum cost, *i. e.*, the greatest good for the greatest number. The Ford car, Singer sewing machine and Remington typewriter are good examples.

The same general principles can be applied to shipbuilding, particularly in countries where the volume of business is so proportioned to the number of plants that each can specialize along certain definite lines. There are different designs of cars, sewing machines and typewriters, each made by the same plant but for different purposes, so that even where standardization is most developed we do not find absolute uniformity.

Portugal to Have Bargaining Tariff

By a decree of August 25, promulgated August 23, the Portuguese Government, according to advices received by the Department of Commerce, is authorized to introduce and bring into force immediately a new customs tariff, revising the rates of the double scale of maximum and minimum duties which have been in effect since November 24, 1921. This decree gives effect to the bill for this purpose introduced last May.

The projected tariff is to be revised again in 1923 and then adjusted to current conditions every five years. The basic rates may, however, be modified by the Minister of Finance, on the recommendation of the Council of Experts for the Customs Service. The government is authorized to conclude reciprocal commercial agreements with foreign countries in which the "minimum" tariff is to mark the limit of concessions on the part of Portugal. Such agreements are to remain in force not over one year.

Of particular importance to American exporters is the provision that during a period of six months from the date of publication of the new tariff any complaints may be presented to the Council of Experts for the Customs Service. After investigation of the complaints, the Council of Experts is to present their opinion to the government, which is authorized to make such necessary corrections in the tariff as seem advisable.

Recent Developments in Marine Insurance

Shipping Board Ratings Completed—Casualty Returns—Unrepaired Partial Losses—"Certificate" Vindicated—Better Hull Rates Wanted

By "Bordereaux"

FINAL recommendations of the various sub-committees of underwriters with respect to the rating of Shipping Board vessels for cargo purposes have all been turned into the central committee and the consolidated report has been transmitted to the Washington authorities. Liner ratings have been granted to a number of operators in particular trades, and "approved steamer ratings" have been given all of the old established operators. Uniformity has been arranged for as between different trades in which substantially the same basic conditions prevail between tonnage and other operating details of Shipping Board and competing lines.

The recommendations are made on the condition that they shall remain in force only so long as the vessels operated by the several Shipping Board agents are maintained in a condition of upkeep which meets with the approval of the United States Salvage Association, and are not loaded beyond their assigned marks. The Shipping Board has agreed to this.

For the information of the underwriters, arrangements have been made with the Salvage Association to issue periodical bulletins advising the names of the ships in the hands of the various operators which may be approved by it for the classification herein provided. Notice of the withdrawal of such approval, and also of any instances of overloading, will be promptly sent out to the underwriters.

The Conference Committee of the underwriters expresses the earnest hope that the various cargo insurers will recognize the improved conditions by adopting the recommendations. In this connection attention is called by the committee to the effort of the present managers of the Fleet Corporation to increase the efficiency of their operating agents and to promptly meet the reasonable requirements of the United States Salvage Association, of which ample evidence has already been had, and also because of their promise to extend to cargo claims consideration equally prompt and equitable with that executed by their privately owned and operated competitors.

Marine Casualty Returns

THE Liverpool Underwriters' Association has issued a classified return of casualties to vessels of 500 tons gross register and upwards, which have been posted in the loss book during the month ended September 30, 1922. Taking into account both British and foreign vessels, steam and sail, it shows the following record: Weather damage, partial losses, 28. Founderings and abandonments, total losses, 3. Strandings, total losses, 6; partial losses, 127; total, 133. Collisions, total losses, 3; partial losses, 143; total, 146. Fires and explosions, total losses, 1; partial losses, 57; total, 58. Missing, 1. Damage to machinery, shafts and propellers, partial losses, 75; other casualties, 12; total, 87.

The number and total gross tonnage of vessels lost, posted in the loss book during the month of September, 1922, were as follows: British, sail, none; steam, 3; gross tonnage, 5,898. American, sail, none; steam, 1; gross tonnage, 691. Japanese, sail, none; steam, 1; gross tonnage, 989. Rest of the world, sail, 2; gross tonnage, 2,721; steam, 7; gross tonnage, 18,701. For September, 1921, the total of gross tonnage casualties in the entire world was 29,789; for September, 1920, the same item was 32,338.

How Unrepaired Partial Losses Work Out

IF an unrepaired partial loss on a hull is followed by a total loss during the currency of the policy it cannot be collected from the underwriters. And yet, if, at the expiration of the policy, repairs have not been made, the underwriter is obliged to pay for the same, even though a total loss occur under the subsequent policy before repairs have been made. The logic behind this rule rests on the ground that the valuation under the renewal policy would not be as high as under the first policy, due to the unrepaired condition of the ship; that is to say, the subsequent total loss payment would be reduced to the extent of the unrepaired damage. By this reasoning there are instances where the owner is able to recover more than the value of the vessel, because frequently the renewal policy is placed some time previous to the expiration of the first policy and while the vessel is still in sound condition. After placing the renewal policy on the same valuation as the original policy, and before the expiration of the first policy, should a loss occur which is not repaired before the attachment of the second policy, then the underwriter on the first policy must pay the estimated cost of repairs. If a total loss then occurs under the second policy before repairs are made, the shipowner will have recovered more than the amount of the insured value of the vessel.

Displacement Invention

A DEVICE has been invented by a French ship engineer, according to a report recently received from Consul Wesley Frost, of Marseilles, France, by which the amount of water displaced by a vessel can be ascertained at any given time. It consists of a water tube or gage installed in the center of a ship. It is very simple in construction and can be installed at a minimum of expense. Underwriters are interested in the invention, because of the opportunity it affords for securing at any time an accurate indication of the weight of the cargo aboard.

"Metal Mike"

INSURANCE men are always alert to measure the advantages to be derived from new inventions that may have a bearing upon the safety of ship and cargo. Their attention has been called to the satisfactory working of a mechanical device, popularly dubbed "Metal Mike," that, it is claimed, will hold a ship to her course at sea without the aid of a quartermaster. Should the vessel deviate from the set way, warning is given by the automatic ringing of a bell. This interesting steering apparatus is not employed in entering harbors. It was first used experimentally on a German steamer in 1915, but never on an American ship until a week or so ago.

New Tariff on Ship Repairs

THERE is a feature in the new tariff that gives promise of concealing a vigorous back-fire for marine underwriters. That is the ad valorem tax of 50 percent on the cost of repairs to vessels of American registry when effected abroad, unless caused by stress of weather. Prominent insurance men pronounce it "outrageous," and see in it a serious handicap to the extension of our merchant marine. The penalty for non-disclosure is the confiscation of the vessel. The question arises whether, in event of a claim for repairs on which the tax is collectible, the underwriters can be required to pay the tax. This feature of the new law means that American vessels will have to be repaired in American shipyards where, it is generally believed, costs are considerably higher than those charged by European or British repairers. It would seem that the new tax prohibits the effecting of repairs, to any great extent, abroad, thus imposing a burden of 50 percent additional upon American ships.

Extra Charge for Buffalo Lay-ups

IN consequence of the slowness of the Government in making necessary repairs to the breakwater at Buffalo underwriters are imposing an additional premium of three-quarters of one percent on boats laying-up at that port through the present winter. The regular lay-up charge is twenty-five cents; which means that the additional cost will bring the premium up to one percent. Lake hull underwriters held a special meeting at New York a few days ago for the purpose of discussing the situation, and a representative was sent to Buffalo to study conditions there and report back to the underwriters. The result has been a serious discountenancing of using Buffalo for laying-up ships under prevailing circumstances.

London Reduces Tank Steamer Rates

A BIG break in tank steamer rates is reported from England. Underwriters complain of a slender margin of profit at the old rate of 4½ percent, and they fear the worst now that tankers are being freely covered at 3½ percent. A large portion of the orders of this kind come from America, where some of the largest fleets are owned. On these the all-risks rate of 4 percent has been for American coastwise trade, with an additional premium of one percent for Institute warranties. These risks are now being placed at a flat rate of 3½ percent, with an additional ½ percent for Institute warranties. This brings the rate, with full transatlantic privilege, to a point one percent less than it was a year ago.

The "Certificate" Vindicated

THERE is great satisfaction among insurers over the recent decision of Mr. Justice Sankey, of the King's Bench Division of the English court, to the effect that a marine insurance certificate is a valid tender when substituted for the original policy. Our readers will recall the mild consternation with which American underwriters received, a year ago, the decision of Mr. Justice McCardie, also of the King's Bench, in which he ruled against the substitution of a certificate for a policy. That judgment has had little effect upon the continued use of the ever-popular, time-saving certificate, but occasionally a bank or ultra-cautious shipper would complain that he did not feel secure in the face of the finding of the British court. Now comes Mr. Justice Sankey, of equal rank with Mr. Justice McCardie, and sustains the certificate. His judgment was given in a suit brought by Donald H. Scott v. Barclay's Bank, Ltd., and the full text may be found on pages 502-506, Part No. 7, Vol. 12. of Lloyd's List Law Reports. The language of the judgment reads as follows: "I find that the certificate was a policy within the definition I have given to which no reasonable mercantile objection could be made on the point of it being a certificate as distinguished from a policy."

The suit also developed an objection to the certificate on the ground that it was a "dollar" insurance against a sterling letter of credit; but this was also brushed aside by the Justice as being without merit.

Bureau of Shipping's Slate

A COMPLETE slate for its board of managers has been placed in nomination by the American Bureau of Shipping for election at the meeting of January 31. All are up for re-election with the exception of George J. Baldwin, of the American International Corporation, who wishes to retire, and in whose place appears the name of Asa F. Davison, general manager of the United Fruit Company. There is to be an addition to the regular list in the presentation of the name of H. A. Magoun, vice-president of the New York Shipbuilding Company. The Board, as nominated, is as follows: John S. Ashley, Louis F. Burke, H. L. Coulby, William J. Davidson, Asa F. Davison, William A. Dobson, Homer L. Ferguson, Richard D. Gatewood, Edward C. Gillette, William R. Hedge, William H. McGee, Samuel D. McComb, Frank Gair Macomber, Charles E. Mather, H. A. Magoun, Frank C. Munson, Charles R. Page, Walter Wood Parsons, Antonio C. Pessano, Joseph W. Powell, H. H. Raymond, John C. Rohlfs, Benjamin Rush, Alfred Gilbert Smith and Joseph J. Tynan. Douglas F. Cox, of Appleton & Cox, and A. F. Davison, of the United Fruit Company, were added to the list of members. It is proposed hereafter to have special sub-committees of the Technical Committee on Naval Architecture and that on Marine Engineering appointed.

Deposits and Forced Sales

THERE is current among underwriters an increasing dissatisfaction with what they regard as flagrant culpability on the part of many shipowners in transfering to their own funds general average deposits and monies realized from the sale of damaged cargoes. The proper custodians for such funds are the regularly selected trustees. Furthermore, it is felt that there is too much delay in distributing the proceeds of cargo sales, resulting in serious disputes with respect to interest due the owners of the money. The evident disposition is to enforce these objections upon shipowners with considerably more firmness than has been the custom of recent years.

Better Hull Rates Wanted

ONCE again the season for the renewal of hull rates has rolled around and with it comes a determination on the part of underwriters to have more rate. It is pointed out that values have continued to decline and that there is no immediate prospect of their attaining a higher figure. Added to this is the meager reduction in the cost of repairs, by no means proportionate with the fall in values. These two elements enter vitally in underwriting calculations as respects particular average costs. They bring the premium volume down and, at the same time, compel the insurers to make disproportionate expenditures out of a decreased income. The difficulty is increased because such a situation invites an abnormal volume of particular average claims. The market would have a better chance to right itself, if it were less extensive than it is at the present time. With so

many companies writing insurance there is too much competition, the result being that all sizes of hull lines are absorbed with ease. Brokers find no difficulty in placing even undesirable hulls, and they can secure rates that practically preclude hope of even the narrowest margin of profit to the underwriter. Violent competition has already sent tanker rates still further down, and the prospect is that the end is not yet in sight.

Co-operation in Lay-up Returns

AFTER more or less discussion Lloyds and company underwriters in London have reached a co-operative arrangement by which claims for returns on account of vessels laid up idle in port shall be submitted to a central examination. A joint committee is to sit daily at the Institute of London Underwriters and claims of this character are to be laid before it for consideration. Upon the approval of such claims by the committee all the underwriters concerned are to settle at once without going any further into details. It is confidently felt that such an arrangement will prove advantageous to both brokers and underwriters, in that it will economize time and introduce uniformity in method.

Unit Type Packing Adapted to Marine Engine and Valve Service

A UNIVERSAL unit type packing, composed chiefly of shredded asbestos, graphite and finely divided anti-friction metal, is being marketed by Metalastic, Inc., 280 Broadway, New York. It is claimed that this packing is suitable for every type of stuffing box and valve in the engine room since it is in shredded form and takes the shape of the box or valve in which it is placed. Its composition is such that it will resist acids, ammonia, carbon dioxide, brine, etc., and has withstood pressures up to 8,800 pounds per square inch without blowing out.

It is claimed that the universal feature eliminates maintaining a variety of packings for engine service. Metalastic is guaranteed to have features of self-lubrication and not to score rods. In this connection the company states that it has been used successfully in steam turbines running at 3,600 revolutions per minute under 185 pounds' steam pressure and at a temperature of 480 degrees F. for twenty months without re-packing. It is claimed that the packing never solidifies and can be removed at any time and used again.

President Harding Expresses Warm Interest in American Marine Week

October 28, 1922.

My dear Secretary Denby:

I learned through Col. E. A. Simmons, president of the American Marine Association, that you are to address the banquet of the Society of Naval Architects and Marine Engineers in New York on November 9. It was with much regret that I was compelled to decline the invitation to be present at the same time, and I am now writing to ask you to express to the gathering my warm interest in the work of this organization and my conviction that it represents a most useful contribution to the development of American maritime interests. I am sure I do not need to add much to what I have said on other occasions concerning my profound interest in and concern for the future of the American merchant marine. Its development and continued usefulness will not fail to constitute a large contribution toward the broadest material prosperity and the truest security of our country. It is always a satisfaction to acknowledge the debt which is owing to such volunteer organizations as the American Marine Association for the efforts in behalf of this great cause.

Most sincerely yours,

(Signed) WARREN G. HARDING

October 25, 1922.

My Dear Mr. McFarland:

I regret exceedingly that it is not possible for me to be in attendance at the banquet of the Society of Naval Architects and Marine Engineers, which is to be held on the evening of November 9th, in connection with the program of observances of American Marine Week. With all my heart I wish I might be a participant on that occasion. No one purpose more enthusiastically enlists the attention of the present administration at Washington than that of turning our vast assets in ships into a live and efficient Merchant Marine. Every day adds to the conviction that the upbuilding of our Merchant Marine is of first importance in assuring our national defense and of incalculable importance in maintaining America's fitting place in the commerce of the world. It would be a pleasure to me to express some of my hopes to those who will be present at your annual banquet. Since I am unable to attend I will thank you to convey my very cordial greetings and to express the hope that American Marine Week and the notable meeting of your society will add to American conviction that we must establish and maintain this agency of transportation on the high seas if we are to maintain a position of becoming eminence in the world of trade.

Very truly yours,

(Signed) WARREN G. HARDING

Mr. Walter M. McFarland,

"American Marine Week" and the Marine Exposition Arouse Popular Interest in Merchant Marine

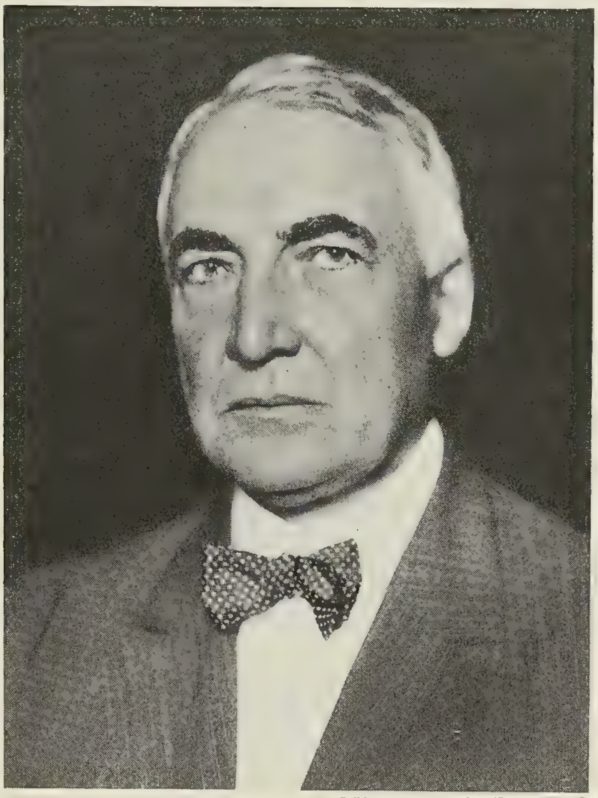
Secretary Denby Delivers Message from President Harding at Naval Architects' Annual Banquet Urging Support for Shipping

FROM the opening at eight o'clock Saturday evening, November 4, until the closing hour on the following Saturday evening, November 11, American Marine Week at the Grand Central Palace, New York City, was one continuous session of business, technical and social events. Practically every organization in the marine field was represented at at least one function and, from the President of the United States down to the men who man our ships, sincere and enthusiastic support was freely given.

The outstanding new feature of the week was the informal conference on "Standardization and Simplification," which was held in the Auditorium, Exposition Hall on Friday, November 10. About 100 delegates from maritime associations and societies, Government departments, and others interested in this subject from the shipbuilding, equipment manufacturing or ship operating companies were present.

Secretary Hoover Interested

Secretary Hoover is very much interested in the avoidance of waste in all industries and under this subject standardization and simplification play a most important part. The Secretary was unable to attend but was personally represented by Mr. R. M. Hudson, Division of Simplified Practice, Department of Commerce.



©Underwood & Underwood

President Warren G. Harding

In opening the conference Col. E. A. Simmons, president of the American Marine Association, explained the attitude of the Department of Commerce. The point of view of the Department is, according to the words of Mr. Hudson, that the one thing which must be avoided in the promulgation of this subject is any inference that the Government is trying to interfere or assume the direction of proceedings, a matter which is thoroughly one of self-determination for the industry. "We want to cooperate and gladly place all our facilities at the disposal of the group, if it desires to work out a program of simplification and standardization."

It is only fair to say, however, that the Department of Commerce has been of great assistance to the industries along these very same lines and has made it possible for them to secure beneficial results.

Object of Meeting

It is hoped in this country that we may accomplish what the British Engineering Standards Association has been working on for the last four years. This work was initiated in Great Britain in 1918 by the Board of Trade. Actual work was started in March, 1919, by the formation of two committees, one on ships' fittings and one on ship machinery details. During the meetings, which were held periodically, of the sub-committees formed covering the various sections or "panels" having to do with practices in defined districts, representatives from the Admiralty, the Board of Trade, Lloyd's Register of Shipping, the British Corporation, leading marine equipment companies and representatives from the foremost British shipping companies, assisted in the discussions.

Mr. Hudson's Paper

The paper read by Mr. R. M. Hudson at the meeting covers the objects to be realized and is published in full on page 746 of this issue.

The interest in standardization shown by all of those present was of a very practical nature. Every one expressed a complete willingness to cooperate in any way possible in the furtherance of this important undertaking. A motion was presented and passed that a committee of five or more individuals be appointed by the Chair to investigate ways and means for accomplishing the desired results of standardization.

The opinion was freely expressed after the meeting by prominent naval architects and other representatives that this was one of the most practical steps which has been undertaken in the marine field. With this in mind, the fullest co-operation may be expected from individuals throughout the shipping and shipbuilding industry. Mr. Carl E. Petersen, naval architect of the United States Lines, expressed the following comment:

> "The present period of depression is an opportune time in which to make a concerted effort to bring together the principals concerned and endeavor to establish shipbuilding standards; in a moderate way first, followed later on by a larger scale. The factors making for successful effort in this direction would include (a) full representation, (b) an agreement of the principals to abide by the findings, and (c) provision for modification of the standards when necessary in order to insure progressive standardization."

The Marine Exposition

As to the Exposition itself, the pictures of the booths illustrating this article speak for themselves. It was a great show, giving everyone an opportunity to inspect the products of all branches of the marine industry. Speaking of new devices and new products, this exposition easily led all previous events in both number and variety. It was difficult to cover them all in the November and December

issues of the magazines and in the Daily Bulletins that were issued during the week.

The best indication of the success of the show is that at this writing over 50 percent of the available main floor space for the 1923 Exposition has been definitely taken or requested. The membership of the American Marine Association, which has staged the Exposition for the last two years, is composed of the companies exhibiting and is strictly on a co-operative basis. Before the exhibitors got together and formed this association, outside parties had control and used the shipbuilders and manufacturers of those things with which ships are equipped as a vehicle through an exposition of this kind for making money for themselves.

The various marine organizations now realize that their own selfish interests demand a much greater participation in all that concerns the welfare of the American merchant marine. And it is also due to this realization that a far larger number of shipping and shipbuilding men attended this exposition than any previously held. The total attendance over and above the naval architects and marine engineers who were given special invitations amounted to 42,600.

Opening Night

The exposition was formally opened at eight o'clock November 4 by Col. E. A. Simmons, while at the same time the Commandant of the Brooklyn Navy Yard, Rear Admiral C. T. Vogelgesang, delivered an address which was broadcasted from the W. E. A. F. station. A concert was given by Todd Shipyards Corporation Marine Band.

Col. Simmons in referring to the last "American Marine Week" said in part:

"At that time the international conference on the reduction of naval armaments was in session in Washington. To our minds the result of that conference showed the necessity for still greater activity inasmuch as it was clear that our national safety would demand an increase in activity in the merchant field at least equal to the forced drop in the operations of our Navy. We are still of that opinion; and that fact, plus the commercial aspect, has stimulated our efforts, resulting in this great Exposition and the events of the coming week. Is it not significant that substantially every organization in the marine field is now co-operating with the American Marine Association that no stone may be left unturned to make the gravity of the situation known to every citizen in the hope that the nation will awake before it is too late."

"We must keep our Navy up to the highest standard of efficiency and we must buttress it with a merchane marine," declared Rear Admiral Vogelgesang in his address over the radio. "To deny a subvention that will give our merchant marine an equal chance with that of other nations is to stultify the development of one of the greatest factors that will govern our future prosperity economically, and our future national security."

Navy Night

Navy Night was fittingly observed on Monday evening, November 6. A large number of naval men were present, including Admiral Vogelgesang, commandant of the Brooklyn Navy Yard, his staff and many other officers. Just before Captain R. D. White mounted the platform to address the Exposition, the country's flag and the Admiral's ensign were broken out while the Brooklyn Navy Yard Band played the "Star Spangled Banner."

©Harris & Ewing

Herbert Hoover, Secretary of Commerce

©Harris & Ewing

Albert D. Lasker, Chairman, United States Shipping Board

©Harris & Ewing

Edwin Denby, Secretary, United States Navy

Captain White delivered a very stirring speech, appealing for an adequate merchant marine to go hand in hand with an adequate Navy. Referring to the merchant marine, Captain White said in part:

"It is only in recent years that far-sighted businessmen in the United States have begun to turn their eyes abroad for opportunities to invest their money and apply their talents. Now, the richest opportunity that appeals most to American imagination is the wealth that lies in the seagoing carrying trade.

"We are late in seeing this opportunity but see it we must, for that is the vital problem facing us at the present time. It is only fair that we should carry, and profit thereby, our just proportion of our own commerce.

"Many obstacles beset our accomplishment of this end. These are too well known to shipping men and, for that matter, to the American public for me to enumerate them here, only permit me to say that the rum question is one of the least.

"But there is one to which I cannot fail to call your attention without failing in a duty I owe to you and to my calling, and that is the necessity of support for an adequate naval force to protect such merchant fleets as may fly our flag. History teaches us that no nation has ever become great or remained great upon the sea unless possessed of and utilizing to its full advantage an adequate efficient Navy."

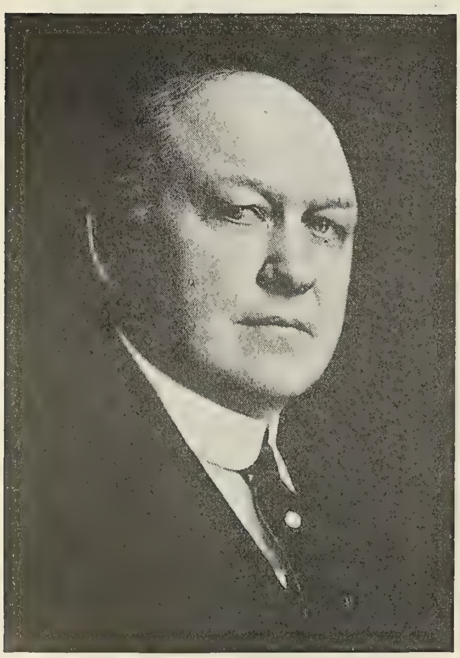
Government Radio Inspector Explains Wireless Communication

At 3 o'clock Tuesday afternoon Arthur Batcheller, chief radio inspector, Second District, Department of Commerce, delivered to an attentive audience in the auditorium of the Grand Central Palace, a most interesting and instructive address on "Radio Communication," illustrated by films and lantern slides. He explained some of the fundamental technical principles upon which radio communication is based and reviewed briefly the United States laws and international treaties relating to radio communication. In addition he described the important part that the Radio Inspection Service of the Bureau of Navigation of the Department of Commerce plays in the orderly operation of this indispensable agency of national and international commerce. Many interesting facts were brought out in the statistical data given, showing the wide range of activities covered by official, commercial and amateur radio installations.

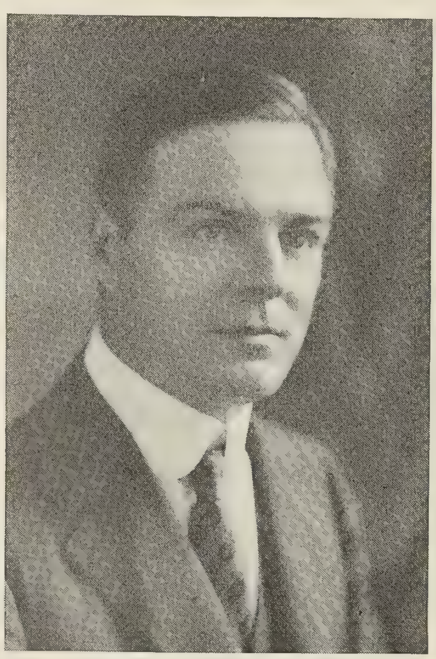
A Big Smoker

On Tuesday evening a large smoker was given by the Ocean Officers' Conference in the auditorium of the Grand Central Palace which was presided over by Mr. William Murray. A very interesting program, consisting of motion pictures, vaudeville and addresses was enjoyed by masters, mates, pilots, engineers, radio telegraphers and their friends. The Tidewater Oil Company furnished every one with a pipe and a can of tobacco.

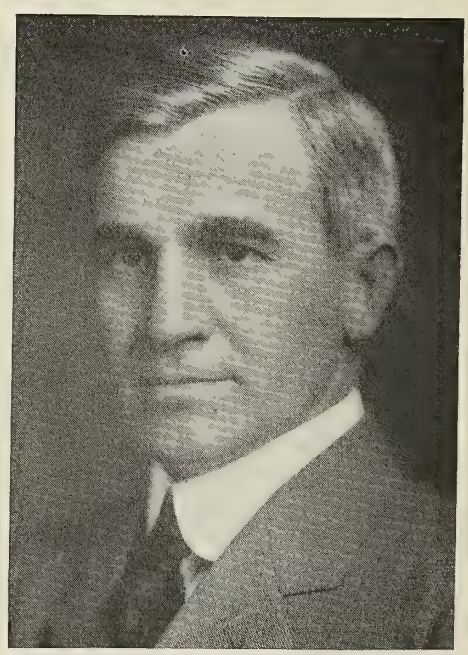
Mr. F. V. Smith of the General Electric Company gave a very interesting lecture on "Ship Propulsion" and told what the General Electric Company had done in developing the electric drive.



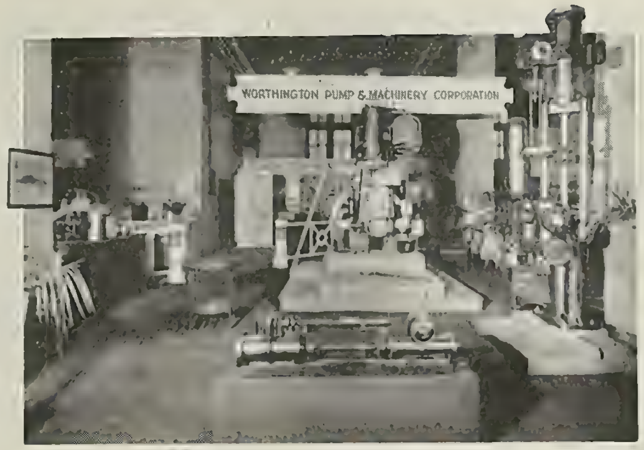
H. H. Raymond, President, American Steamship Owners' Association

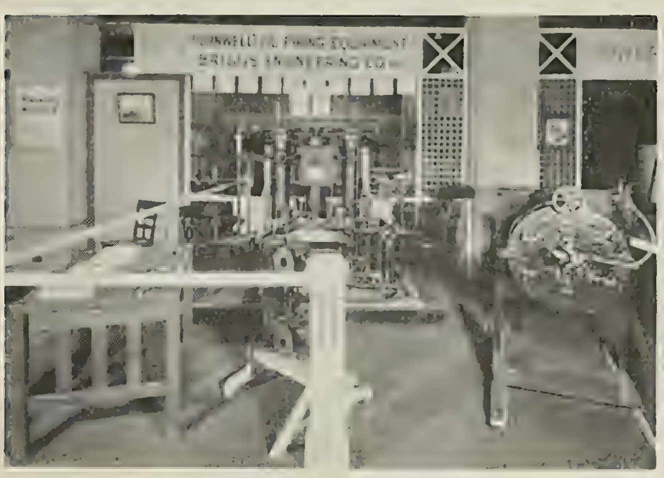


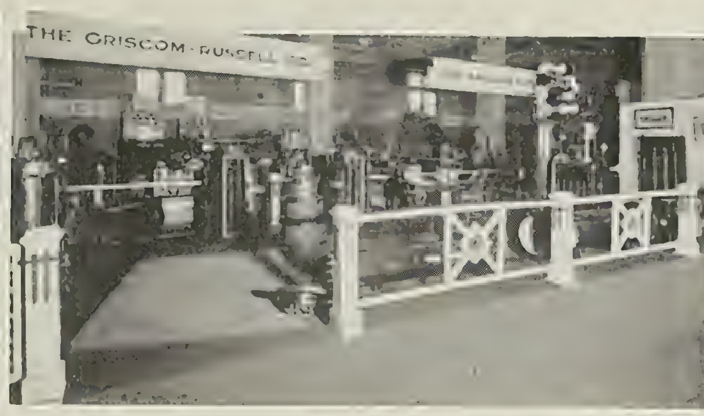
J. L. Ackerson, President, Atlantic Coast Shipbuilders' Association

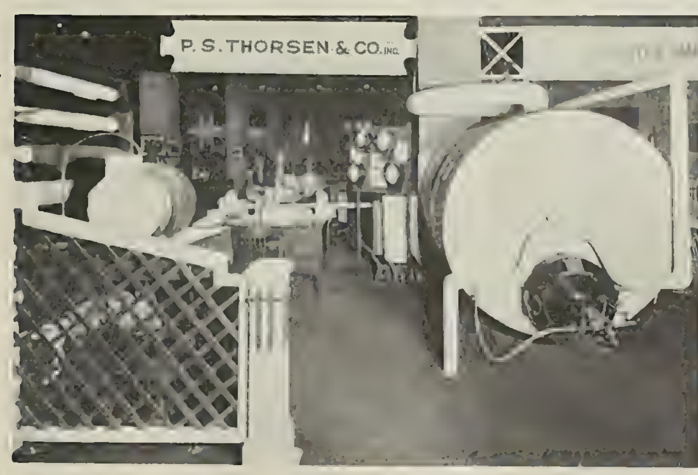


Homer L. Ferguson, President, Newport News Shipbuilding Company









Views of Exhibits at the Marine Exhibition

Captain John F. Milliken of the Neptune Association spoke about the wages that would have to paid to competent officers on American ships in order to prevent them from taking positions on shore. Mr. Samuel Lamont spoke on "Thrift." The Sperry Gyroscope Company furnished a moving picture entitled "The Romance of the Gyro."

Convention of Naval Architects and Marine Engineers

On Wednesday and Thursday the Society of Naval Architects and Marine Engineers held their thirtieth annual convention in the auditorium of the Exposition Hall, Grand

Col. E. A. Simmons, President,
Marine Engineering & Shipping Age,
Woolworth Building,
New York City.

My dear Colonel:-

I take the present to express my pleasure and gratification at the success of the Exposition held at Grand Central Palace. From a large number of attendants I heard nothing but praise for the successful efforts put forth by those in charge of the Exposition, to which you personally were a large contributor.

The Exposition also served to keep alive the need for a Merchant Marine, and I am of the opinion that expositions such as was held at the Grand Central Palace are bound to prove a large contributing factor in developing this important subject. I cannot but help to feel that good results are bound to come from the efforts spent and sincerely hope that another Exhibit will be held next year. While our Exhibit was not very large, yet we feel that we were an interesting part of the Exposition and we are hopeful that our Association will also derive benefits from our being associated with the undertaking.

With kind personal regards, I am,

Yours sincerely

C H Potter

President.

CHP:B

President of Maritime Association Indorses the Marine Exposition

Central Palace. These meetings are fully reported on pages 771-780 of this issue.

The annual banquet of the Society of Naval Architects and Marine Engineers, which was held at the Waldorf-Astoria, taxed the capacity of the grand ball room. Tables were placed all around the balcony and out into the reception room. Captain Walter M. McFarland was toastmaster of the banquet and also read the letter from President Harding which appears on page 756.

Secretary Denby's Address and Message from the President

The chief speaker of the evening was the Hon. Edwin Denby, Secretary of the Navy, whose address was enthusiastically received and applauded. Secretary Denby left no doubt in the minds of his audience that the Administration was determined that the Navy should be kept equal to that of any other country and that it would do everything in its power to establish the American merchant marine on a firm basis. Part of his address follows:

"A Navy as large as any other is the best security against war as well as the surest guarantee that if war comes it will be waged successfully by our country. If people could only realize that in a peace-loving Republic like ours which has no aggressive designs in the world, a reasonable preparedness is not alone our surest guarantee of peace but it is a duty we owe to humanity. A proper Navy does not mean aggression but it does mean the exact reverse. As a nation we have too frequently acted as did the village council which solemnly resolved that the volunteer fire apparatus should be put in a state of repair and well furnished twenty-four hours before each fire.

Merchant Marine Support Necessary

"Fine as it is, the Navy cannot properly function in time of war without other aid. Napoleon once said that an 'army travels on its belly,' meaning that it must have its supplies and its train or it could neither move nor fight. Exactly the same thing is true of the Navy. It cannot fight in distant waters nor travel without its supplies—its fuel ships, its refrigerator ships, its hospital ships, its repair ships, its mother ships for the smaller craft. It would be a vast expense in time of peace to maintain as naval craft only the great fleet that would be needed when the call to battle comes. We have been compelled to rely upon the merchant shipping of the United States to secure in large part these vitally necessary adjuncts to the fighting fleet.

"When President Roosevelt made that splendid experiment of sending twelve battleships around the world, I think he had more motives in mind than one. Among other things, I think he wanted to show the American people the vital need of the merchant marine. Those 12 ships could not have gone around the world or to any distant waters in time of war. We had not the necessary auxiliaries nor the necessary merchant vessels of which auxiliaries could be quickly made and so we chartered foreign shipping and the American armada was made possible by the use of vessels flying foreign flags. It was a striking demonstration of the military need of a merchant marine.

"Yet a more striking event occurred during the Spanish-American War when it was found almost impossible to assemble together enough ships to carry a force of 25,000 men to Cuba. And I well remember how we who were in the Navy then prayed that no wind might blow nor seas rise while these old vessels carried their precious cargoes to the scene of war. This too was because we had no merchant marine worthy the name and only gathered in by hook and by crook enough vessels to actually take the troops that short summer cruise. Had the war been more distant, the season different, and the weather inclement, a pitiful disaster might have befallen the American arms. We of the Navy regard the continuance of our present merchant marine and its increase as a vital necessity for the national defense.

The Country Is Awakening

"I am happy to say there seems to be an awakening now in the United States and it is my earnest hope and belief that that awakening will stir us to pass through Congress at the next session a bill which will encourage and make possible the building and operation of American ships by the employment of the only method we have at present—a subsidy. It will be a subsidy of so peculiar character, however, that it is to be expected that vessels receiving it will in the course of not many years be able to pay back into the treasury all the money advanced by the United States to aid in their operation and I am very happy to tell you what you doubtless know already that the recreation of the American merchant marine is a policy very dear to the heart of the President of the United States. His utterances have shown how earnestly he will endeavor to secure legislation at the special session of Congress, which he has just called for November 20, to keep the flag upon the high seas and to aid the merchants of the United States in their coming struggle for their fair share of the trade of the world. I am authorized by the President to read to you a message of greeting and encouragement."

This message appears on page 756.

Mr. W. J. Love, vice-president of the Emergency Fleet Corporation, gave some very interesting facts comparing our position on the sea in 1916 versus 1922. Extracts follow:

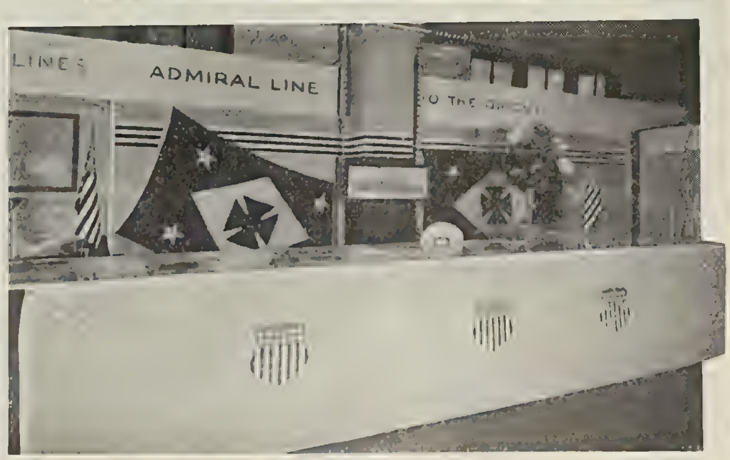
"The entrance of our country into the World War in April, 1917, found our shipping in a deplorable condition, at least with respect to world wide cargo trading, and my entire remarks are on this basis, that is, excluding services to contiguous countries, to the West Indies and Central America. A brief description will be helpful.

Review of Shipping

"On the Pacific there were, I think, only two American flag steamers trading to the Orient—the *China* and the famous *Minnesota*—and those to Australia via our South Sea Island possessions, the old established Pacific Mail Company service to the Orient having disappeared about a year previously.

"There were perhaps eight or ten ships under our flag trading to Central America and the West Coast of South America.

"Off the Atlantic Coast we had the American Line to South-



Views of Exhibits at the Marine Exhibition

ampton, and one or two passenger ships to Antwerp. The Atlantic Transport Company was using the recently acquired ships of the Pacific Mail in its London trade.

"The splendid fleet of the American Hawaiian Company was principally engaged in the Intercoastal trade and to the Hawaiian Islands.

"The fleet of the United States Steel Company was in its infancy, they having a few steamers trading with their products and general cargo in various directions.

"This will give you a fair picture of the activities of American ships in world commerce prior to the war.

Development Since 1917

"Let us now look at what has been done in the development of privately owned lines since 1917. On the West Coast there are two passenger trading ships transpacific, two leading to Australia, and perhaps a dozen cargo steamers to the Orient, Central America and South America. On the Atlantic, we have two excellent services to German ports, and one of our largest manufacturing concerns has increased its fleet to well over 40 bottoms that cover many important trade routes.

"The Intercoastal trade, which is a restricted one, is absorbing today between 600,000 and 700,000 tons of the best American ocean-going cargo ships. Of course, this tonnage would be available in time of war for any service it might be called upon to fulfill.

"This comparison, therefore, of our position in 1916 vs. 1922, is anything but a pleasant one, for it shows that so far as privately owned shipping is concerned we have made little or no progress in developing services to move our exports or imports in world-wide trading. If it is the country's wish that we have a merchant marine then it can only be successful in private hands who will by energy, ambition, and resourcefulness, if proper laws are enacted, place it in a position to compete freely with the flags of other nations. While it is true that many maritime nations operate ships under restrictive laws, as a rule owners are generally free to take advantage of every means at their disposal to reduce costs of operation to the lowest possible point, and this during periods of depression simply means 'the survival of the fittest.' Are we headed that way, or are we headed the other way? Countries whose laws are too harsh reflect this lack of commercial freedom in the size of their commercial fleet."

Pay Necessary Cost

Homer L. Ferguson, president of the Newport News Shipbuilding & Dry Dock Company, spoke as follows:

"Conditions have changed to such an extent in recent years that it is difficult to see how American papers and American men can be against all laws that will foster the development and growth of the merchant marine.

"We live in a protected country and that our marine must be protected seems proven both by reason and experience.

"Discriminating duties as provided by the law of 1920 having been declared by two Presidents to be out of the question at this time, we are forced to consider the recognized alternative of subsidy.

"We paid so much for lack of merchant vessels during the war that any reasonable cost for subsidy appears trivial by comparison.

"The necessity for merchant vessels, particularly of large fast types, was such as to demonstrate their usefulness to be on a parity with that of war vessels.

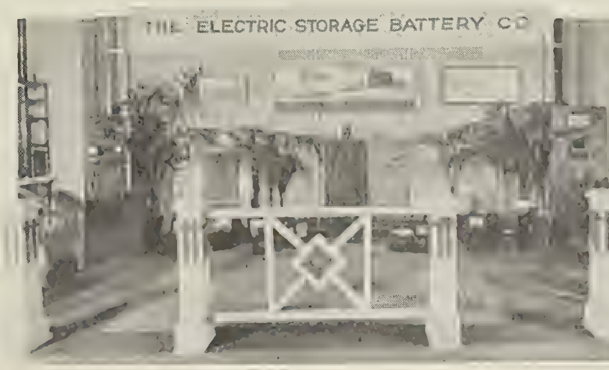
"The limitation of capital naval ships further emphasizes the value of merchant ships, and inevitably transfers the competition from what may not be built to what may be built. The 5-5-3 ratio can only be maintained by providing in practically that ratio all of the necessary elements of naval power including merchant shipping suitable for carriage of troops, and capable of conversion into auxiliary cruisers.

"Otherwise, it follows, we will be left behind and not only will our shipbuilding decay and our shipping industry fade away to its former insignificance, but our position in the world will have been given away without the people knowing it.

"How can anyone believe in the national necessity for an effective merchant marine and not believe in paying what is necessary

View of Center Aisles, Marine Show, Grand Central Palace, November 4-11, 1922

THE ADAMS & WESTLAKE COMPANY



Views of Exhibits at the Marine Exposition

to get it? How can anyone believe in preparedness and in a proper Army and Navy and not believe in providing that great and necessary auxiliary to each—an effective merchant marine?

"Every sound argument for preparedness applies equally well. Free traders and those who believe the earth is rid of wars, will generally oppose doing anything to provide our country with such a prime necessity as a merchant marine. The costly experience of the past few years is lost on them. But our trade and our policies will not always be dominated by others and some day we will share in fair partnership on the sea with the other great nations."

American Marine Association Holds Annual Meeting

The annual meeting of the American Marine Association to discuss the work of the year, the success of the exposition and the reports of committees and finally the election of new officers, held in the Auditorium of the Grand Central Palace, Friday afternoon, was opened at 4:30 o'clock with Col. E. A. Simmons presiding.

In his opening talk the president outlined informally the original purpose for which the association was formed, the gradual development of its powers and broadening of the scope of its activities until it has reached the point this year when over eighteen associations actively engaged in the marine field have been interested in making American Marine Week a success.

With reference to the development of the association and its future possibilities, Colonel Simmons outlined the proceedings of the informal conference on standardization in ship construction and ship operation held in the auditorium that morning and referred to the proposed plan to subdivide the American Marine Association into several parts, such as designing, engineering, purchasing, etc., each part to co-operate with other existing organizations to the end that during the year papers on various subjects would be prepared for presentation and discussion at next year's meeting.

In concluding his address, Colonel Simmons thanked Vice-President Wampler and the members of the several committees, through their respective chairmen, for their tireless energy and splendid co-operation, attributing to them the success of the show and the activities connected therewith.

Following the report of the Secretary, the President called for the report of the Nominating Committee. He explained that while the by-laws provided for the selection, as well as the election, of members of the Executive Committee for the several districts by the members having their offices in those districts, the Nominating Committee had taken it upon itself to recommend men to fill existing vacancies and to provide for vacancies which would occur at the end of the year through expiration of terms of office—the reason being that the Nominating Committee consisted of men from all six districts able to canvass the situation in advance. It was then decided that the representatives from the several districts would act on any recommendations so made by the Nominating Committee. The result was that the following were elected:

District 1. New England States—Charles F. Scott, General Electric Company.

District 2. New York and New Jersey—William Wampler, Ellcon Company; L. H. Korndorf, Federal Shipbuilding Company.

District 3. Pennsylvania, Maryland, Virginia, etc.—James Plummer, Newport News Shipbuilding & Dry Dock Company.

District 4. Gulf States—Ernest Lee Jahncke, Jahncke Dry Docks, Inc.

District 5. Middle West and Great Lakes States—F. C. Bradbury, Crane Company; W. S. Doxey, *Marine Review.*

District 6. Pacific Coast States—H. F. Alexander, Pacific Steamship Company; J. J. Tynan, Bethlehem Company.

Through recent amendments to the by-laws it was necessary to elect two officers only, selection of a Secretary and a Treasurer being left to the Executive Committee. The report of the Nominating Committee recommended the re-election of Colonel E. A. Simmons, of Marine Engineering and Shipping Age, New York, as President, and the election of Frank J. Shipman, of the Texas Company, New York, as Vice-President. They were then elected unanimously.

There was some expression of surprise that William Wampler, of the Ellcon Company, had not been re-elected Vice-President. The fact is that the office was tendered to him by the Nominating Committee and Mr. Wampler declined only because of his inability to give to the affairs of the association the amount of time required.

Maritime Association Day

Saturday, November 11, was Maritime Association Day and Armistice Night. In the afternoon Captain John F. Milliken of the Neptune Association gave an interesting talk on the part that the sea-going personnel had played in the history of our country. Captain Milliken pointed out that during the Revolutionary War the number of sailors on our men-of-war, privateers and merchant ships exceeded in number those in General Washington's Army. He also said that we had more men on the sea than in the Army in the War of 1812.

The Coast Guard

A paper explaining the duties of the Coast Guard, which was prepared by Commander B. L. Reed, was read by Captain Yardell. Commander Reed said that "While the Coast Guard is a military service available for active duty in time of war under the Navy Department, its prime duties are humanitarian, and, in general, have to do with rendering assistance to vessels in distress and saving life and property; destruction or removal of wrecks, derelicts, and other floating dangers to navigation; extending aid to American vessels engaged in deep sea fisheries; protection of the customs revenue; enforcement of law and regulations governing anchorage of vessels in navigable waters; enforcement of laws relating to quarantine and neutrality; suppression of mutiny on merchant vessels; enforcement of navigation and other laws governing merchant vessels and motor boats; enforcement of law to provide for safety of life on navigable waters during regattas and marine parades; protection of game and the seal and other fisheries in Alaska; enforcement of sponge-fishing law; the conduct of the International Ice Patrol for safety at sea off the Grand Banks.

Other papers prepared for the American Marine Week appear elsewhere in this issue.

Electric Drive Control Panels

Two types of electric ship propulsion control panels for turbine and Diesel electric drive were features of the General Electric Company exhibit at the Exposition.

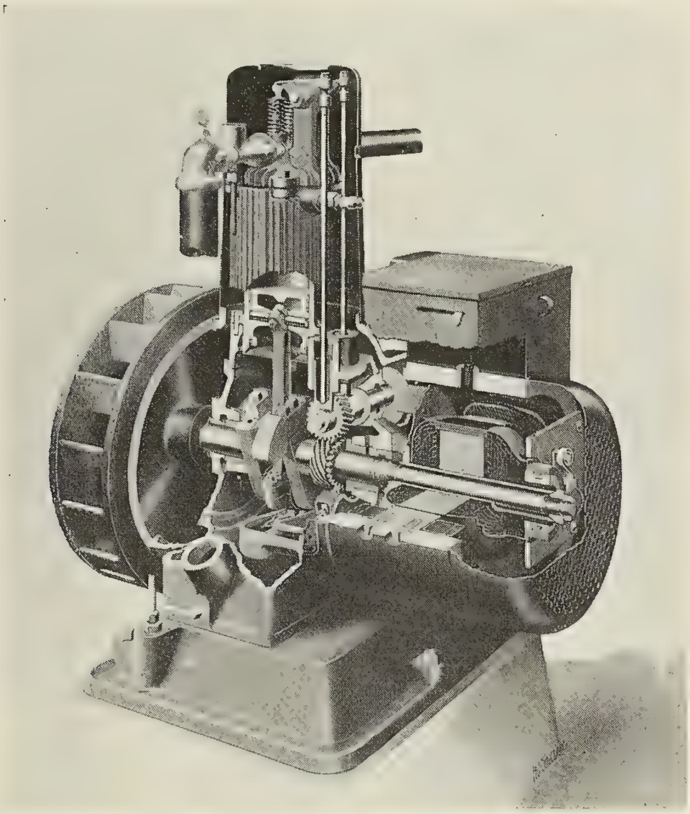
The steam turbine drive control panel was built for the San Francisco-Oakland Terminal Railways. The propulsion equipment with which it is to be used consists of a direct current turbine generator with exciters. The generator is connected to the turbine through single reduction gears. Two motors drive the propellers, the bow motor being run at such a speed that no work is done by its propeller. The astern motor develops 1,100 shaft horsepower.

The Diesel electric control panel on exhibition was a duplicate of that used on the *Golden Gate* in conjunction with the two Diesel engine driven direct current generators driving two motors. The astern motor in this case develops 750 horsepower. This control panel contained the switches for the three control stations; one station in the engine room and one in each pilot house. These switches are so arranged that only one station can be used at a time.

New Devices Exhibited at the Marine Exposition

Marine Light and Power Plant

TWO small marine power plant units recently put on the market by the Westinghouse Electric & Manufacturing Company, New York, were exhibited at the Exposition. These units of $1\frac{1}{2}$ horsepower and 3 horsepower, respectively, are suitable for supplying the necessary current for light and power for auxiliary equipment on small yachts, cruisers and other pleasure craft. They are equally applicable to auxiliary or emergency service on larger ships for signal and deck lights as well as supplementary power in case of accident to the main generating equipment or when the vessel is in port.



Westinghouse Type E-30 Light and Power Plant, with 750-Watt Generator and 4500-Watthour Battery (8 Hour Rate).

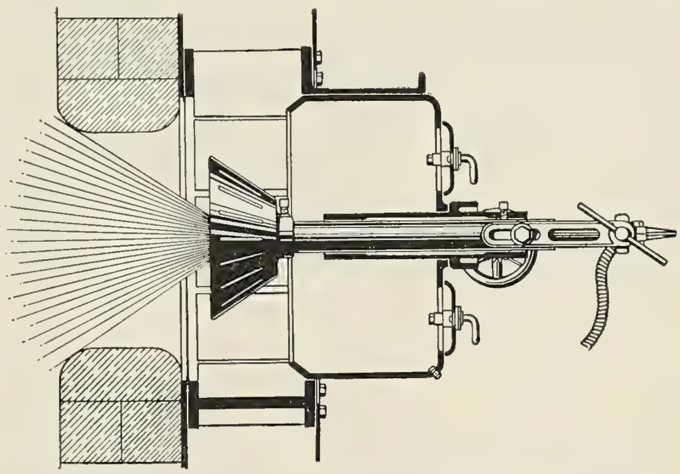
The smaller outfit is driven by a 4-cycle, single cylinder, air-cooled engine, operating on either gasoline or kerosene and runs at 1,250 revolutions per minute. The weight without the battery is 338 pounds. The generator output is 750 watts.

The 3 horsepower unit is run by a similar type engine at 1,200 revolutions per minute and weighs 485 pounds, while the generator output in this case is 1,500 watts at 30 volts.

Batteries supplied with the equipment are of 4,500 or 6,000 watt hour capacity with a weight of 600 pounds for the former and 904 pounds for the latter.

Swinging Front for Oil Burners

THE Bethlehem (Dahl) mechanical oil burning equipment has been improved by the new swinging front which may be used with both natural and forced draft. This new front combines all the features of the regular burners, including the slotted cone, the nine vane air register and hand ratchet adjustable pot air valve. Probably the greatest advantage claimed for the new front is that access to the furnace may be made without taking down the front. The front may be swung aside by simply moving two dogs and removing one lock pin. The front half of the pot swings open with the front itself, leaving the vanes of the air register locked, so that in the case of forced draft any one of a battery of furnaces may be opened without interfering with the draft in the others.



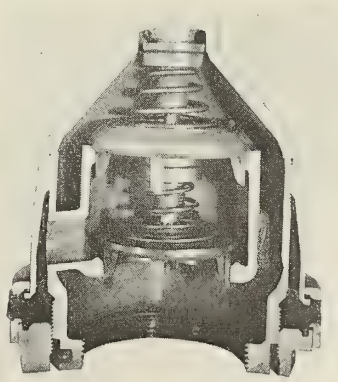
Improved Type of Bethlehem (Dahl) Oil Burner

Cone adjusting handles have also been added and a peep hole cut in the slotted cone which lines up with a peep hole in the door so that the operator can observe the flame at the burner tip from in front of the furnace.

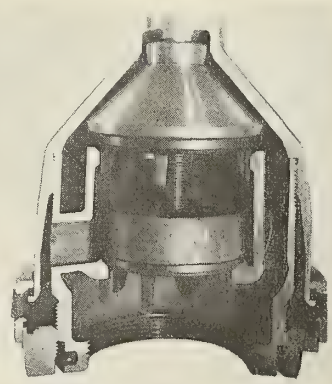
Three Luckenbach ships which are being equipped with the largest Scotch marine boilers ever built are being fitted with this new type front—forty-eight furnaces in all.

Automatic Tank Vent Valve

THE exhibit of the William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa., included among other devices the de Krafft automatic tank vent valve, designed for use on the vent pipes of oil tanks so that in case of accident, such as a collision or grounding, where a tank is punctured and there is danger



Adjustment with Springs on Disks



Adjustment with Weights on Disks

of it filling with water, the valve may be quickly closed, completely stopping vent pipes and preventing the escape of the air from the tank and the water from entering it.

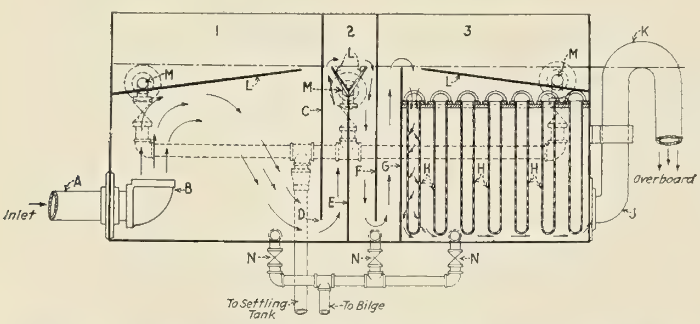
In the device there are two separate valve disks seating on separate seats instead of one disk being seated upon the other. Both of the disks open upward and close downward by gravity instead of one disk opening downward and being held in its place by a spring; the danger of this disk falling open through accident to its spring thus being avoided. The pressure at which it is desired to have the disks operate may be controlled by springs or by means of weights. A wire net screen around the bottom is provided which prevents dirt from entering the valve and acts as a protection against fire. This screen also serves as an indicator to show whether the valve and vent pipe are open or closed.

When the tank is being filled and a pressure is caused in it, the lower disk lifts and the air escapes through the ports and the screen into the air. While the tank is being emptied, a vacuum is caused in it, the air in this case entering the valve through the screen and the ports to the chamber over the lower disk, lifting the upper disk and flowing into the tank through the passage between the ports.

This valve has passed a series of severe tests by the United States Navy Department, and is approved by Lloyds' Register of Shipping, the American Bureau of Shipping, the United States Salvage Association and others.

Bilge and Ballast Oil Filter

For the prevention of pollution in harbor waters by the discharge of ballast and bilge water from oil-burning vessels the Todd Shipyards Corporation has developed a filtering system which was exhibited for the first time at the Marine Exposition. The system consists of moving water by gravitation and filtration by passing the



General Arrangement of Todd Bilge and Ballast Filter Tank

overboard discharge from the bilge and ballast pumps through a specially constructed filter.

The main body of the filter consists of a rectangular sheet metal tank located at any convenient point above the load water line of the vessel. This tank is subdivided into three or more ompartments, designated in the accompanying illustration as 1, 2 and 3. The overboard discharge, consisting of water and oil, from the pump enters the filter tank through pipe *A* into compartment No. 1 and is deflected upward by elbow or bend *B*. Compartment No. 1 being relatively large, acts as a reservoir, and this permits the major portion of the oil contained in the discharge sufficient time to flow to the top of the level in this compartment.

The flow from compartments 1 to 2 is baffled by a division plate *C*, which is open on the bottom only at *D*. Compartment 2 is also fitted with a division plate *E* which forces the water to flow up over it and down behind a third division plate *F*, which is similar to *C*, and separates compartments 2 and 3. The flow of water under and over these baffles permits the oil to rise to the top, due to its lighter gravity, and the final flow into compartment 3 over baffle *G* is relatively free from oil. The water is then passed through filtering cloths *H*, and these cloths entirely eliminate the final particles of oil. It is then carried overboard through pipe *J* and return bend *K*.

Each compartment is fitted with a skimming pan *L* and drain cocks *M*, whereby the oil which floats to the top of the various compartments can be drained from the filter into a settling tank. Each compartment is also fitted with a clean out valve *N*.

Fireroom Temperature Reduced with New Air Register

A feature of the Coen Company, N. Y., exhibit was the air register similar to the type which was developed for installation on the S. S. *President Taft* of the Pacific Mail Steamship Company.

A unique method of obtaining full air openings in the vane wheel has been devised. This wheel slides into position on double threads. Ready access to the interior of the furnace may be had through the front, which is hinged and may be swung aside without the necessity of dismantling any of the parts.

The fireroom records of the *President Taft* on a trip to Japan indicate that the air registers operated satisfactorily, maintaining an average fireroom temperature for the voyage of 90 degrees F., whereas with the former equipment the average temperature was 120 degrees. The air registers on this ship are fitted to Yarrow boilers.

New Balanced Window Sash

An ingenious window sash just perfected by O. M. Edwards, Inc., Syracuse, N. Y., was among the new devices shown at the exposition. The window is balanced by a spring actuated mechanism consisting of two levers with rollers at the outer ends upon which the glass rests. Balancing is accomplished by a compression coiled spring with arrangements for adjustment to correspond with the weight of the glass. All of the mechanism is located above the sill, which prevents the accumulation of water and consequent rusting of the mechanism.

Four Soundings a Minute with New Device

The "Marimeter," patents for which are controlled by Wm. Cramp & Sons Ship and Engine Building Company, was demonstrated at the Exposition by the inventor, Samuel Spitz. The principle on which the device operates is measurement of the time interval between the moment a blow is struck on the ship's bottom by an electric hammer until the echo is reflected from the sea bottom and transmitted back through the water and picked up by a microphone on the ship.

The equipment includes a pedestal located on the bridge, on which is mounted an electric keyboard and an indicator. Microphones are placed on the ship's bottom, on either side of the hull and at the bow. As noted, when a key is pressed a sound is produced at the ship's bottom. Immediately the indicator needle starts moving from zero and continues until the echo is picked up by the microphone, at which instant it stops. The dial is calibrated in fathoms so that the sounding may be read directly.

The apparatus may also be used to determine the distance from one ship to another, to land, an iceberg or other marine

menace. The Navy Department in testing the device has made soundings up to 28,000 feet, at the rate of four soundings a minute.

Sturtevant Sea Speed Engine

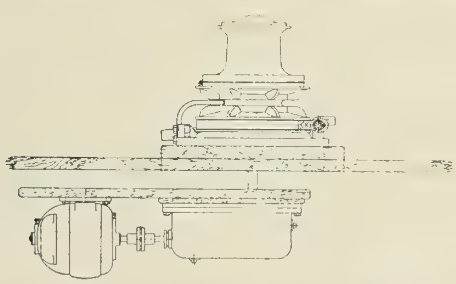
A LITTLE known product of the B. F. Sturtevant Company, Hyde Park, Mass., was exhibited this year—a 75 horsepower gasoline engine especially developed for speed boats.

This engine is of the 4 cylinder four cycle, water cooled vertical type with a bore of 4½ inches and a stroke of 6 inches. It is designed to operate continuously at a speed of 1,500 to 1,600 revolutions per minute. Right and left hand rotation designs are supplied so that a pair of engines may be installed symmetrically in a boat.

Electric Windlasses for Motor Boats

THE American Engineering Company, Philadelphia, Pa., in its exhibit featured small windlasses of the gypsey head and wildcat types especially developed for use on motor boats. The gypsey type unit is driven by a 1/3 horsepower weatherproof marine motor connected through a flexible coupling to the gearing of the gypsey head. The barrel of the windlass is of bronze 5 inches in diameter. The overall dimensions of the machine are: Fore and aft, 26 inches; thwartship, 11 inches; depth below deck, 8 inches; height of gypsey barrel, 7½ inches; weight, 100 pounds. This will lift a 200-pound anchor or loads on the barrel up to 1,000 pounds.

The gypsey barrel wildcat type windlass is equipped with either a 1/3 horsepower or ¾ horsepower weatherproof marine



Gypsey Barrel Wildcat Type Windlass

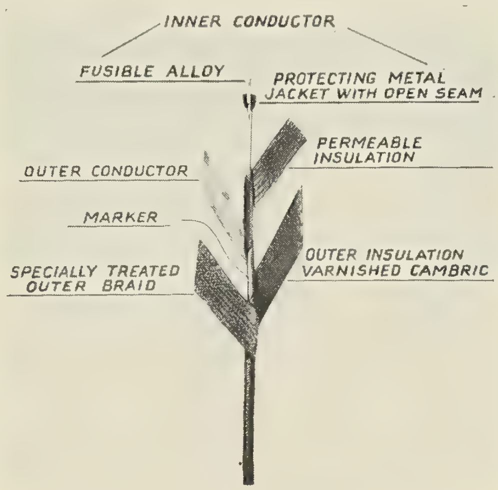
motor. The smaller motor will handle an anchor up to 150 pounds, while the larger will lift 300 pounds. The wildcat can be made to handle chain from ⅜ inch to 9/16 inch inclusive. A toggle operated self-contained brake is furnished, also a deck pipe for the chain. The weight of the unit depending on the size of the motor is from 125 to 150 pounds.

Fire Detecting Wire Automatic Alarm System

A CLOSED circuit automatic fire alarm system depending upon the fusibility of a special type wire, known as "Fire Detecting Wire," was demonstrated at the exposition by the Fire Detecting Wire Corporation, New York.

The system on board a ship consists of various circuits of continuous thermostatic wire each connected with a centrally located control panel and with alarm gongs so that in the event of fire or even of undue heat in any of the compartments an alarm will be given before the fire has become dangerous. The construction of the wire is illustrated below. It is composed of a core of special fusible alloy covered with a protecting metal jacket having a narrow open seam. Next to this is a wrapping of saturated cotton yarn which provides insulation between the core and the outer conductor which is of spirally wound brass tape. A layer of varnished cambric protects against grounds and a varnished cotton braid over all gives mechanical protection.

The soft metal in the core has a fusing temperature of



Construction of Fire Detecting Wire

160 degrees F., but, because of the retarding effect, amounting to 20 degrees F., of the outer casing, the wire as a whole has a fusing temperature of 180 degrees, although in a slow heat the fusing point is reduced to approximately 160 degrees since the entire mass has time to become thoroughly heated.

In operation the soft metal core first becomes plastic, and at the instant of fusing spurts through the permeable insulation making electric contact with the outer conductor or brass tape. This contact operates the system and sounds the alarm.

An installation may be either code or non-code, according to requirements. In the code system single stroke gongs are placed at various points in the protected area. The fusing of the wire in any circuit will cause the code number for that section to be sounded on all gongs in the system. Each section is provided with an alarm box by means of which the system can also be operated manually.

In the non-code system each section of thermostatic wire is led to a centrally located control panel on which is mounted an indicator having a drop for each compartment. The fusing of the wire in any circuit shows on the indicator the section affected and rings a series of vibrating gongs located at various points in the protected area.

Features of Ice Machine Exhibit

AMONG the various types of ice machine equipment shown by Brunswick-Kroeschell Company, New Brunswick, N. J., was a new design of piston valve engine driving a 2-ton ice machine. The complete compression side of this machine was shown.

The engine is the latest type steam reciprocating engine developed for ice machine service, having in addition to the piston valve feature a channel frame which permits ready access to the connecting-rods and stuffing box.

One of the few direct motor driven ice machines was also shown. This unit consists of a 1-ton ammonia outfit driven by a 3 horsepower motor.

As a result of the recent consolidation of the Brunswick Company with Kroeschell Brothers, of Chicago, a Brunswick-Kroeschell carbon dioxide machine was also included in the exhibit.

Measuring Liquids at High Temperatures

IMPROVEMENTS in the Empire fuel oil meter make possible the measurement of liquids at high temperatures. The standard type meter for measuring fuel oil on board ship produced by the National Meter Company, N. Y., will withstand a working pressure of 300 pounds per square inch and a hydrostatic pressure of 600 pounds per square inch. This meter has been approved by the United States Navy and in the reconditioning of the *Leviathan* nine meters are being installed.

Electric Telemotor Perfected

THE Hyde Windlass Company, Bath, Me., exhibited a new and original application of the induction principle to an electric telemotor. This telemotor has been developed at the company's laboratory recently in order to furnish a dependable steering apparatus for steamships.

By moving the steering wheel in the pilot house any angle of rudder is automatically obtained. This is a contactorless type telemotor having a positive follow-up. Only three small wires are required between the steering wheel in the pilot house and the steering gear aft. The telemotor was shown operating two types of electric steering gears.

Utilizing Waste Heat from Diesel Engines

REPRESENTATIVES of Row and Davis' Engineers, Inc., N. Y., took special interest in explaining a new steam generating outfit developed by the company for extracting heat from the exhaust of Diesel engine installations.

The steam thus generated is available for heating a ship and for such purposes as supplying steam to the RanD system for rendering fuel oil mobile, without the use of tank heating coils.

Two ships, the *City of Jacksonville* and the *Ashby,* are already equipped with the new steam generators.

Largest Brass Valve in the World

The Crane Company exhibited in its booth the largest brass valve ever made. This valve, which was built for the United States Navy, is a 39-inch gate type and weighs 4,600 pounds.

Protective Coating for Insulated Surfaces

WHEREVER magnesia and other insulating materials are used on boilers, tanks, feed water heaters, oil heaters and in other applications "Thorkote" a product exhibited by P. S. Thorsen and Company, 81 Coffey street, Brooklyn, N. Y., may be applied as a waterproof covering. This material is in plastic form when it is applied to the insulating covering. After application it becomes hard, but may be easily repaired.

The advantages claimed for "Thorkote" are the fact that it is cheaper than sheet iron, has insulating qualities itself, is waterproof, has no open seams, thus eliminating the chance for water reaching the magnesia, and cannot rust.

New Soot Blower Head

THE Diamond Power Specialty Company, Detroit, Mich., exhibited the model G-2M blower head designed especially for marine work, in restricted spaces. It has a minimum projection from the casing of a watertube boiler of 7½ inches. Special features include the stuffing box, packing gland, stop system and chain operation.

The front end blower for Scotch marine boilers also exhibited is designed for cleaning double end boilers where the space between the rear of the boiler and the bulkhead makes necessary the operation of the soot blower from in front of the boiler. The device is operated through the flue doors. No threaded parts of the blower are exposed to the steam.

Diesel Electric Drive

FOR purposes of illustrating the application of Westinghouse direct current motors and generators to Diesel electric ship propulsion, a complete model layout of a typical installation was shown in the Westinghouse booth. The electric equipment is adaptable to practically any make of Diesel or semi-Diesel type engine.

The features of electric drive especially emphasized by the demonstration are flexibility of the control which is based on the Ward Leonard system of operation, the fact that the most economical engine speed may be maintained at all motor speeds and that in case of trouble one unit may be cut out and repaired with only a slight reduction in the speed of the ship.

Casting Metals by the Centrifugal Process

A NUMBER of highly polished cylinders of cast bronze made by a new centrifugal method of casting non-ferrous metals were included in the exhibit of the American Manganese Bronze Company, Holmesburg, Pa. Pump lines, bushings and gear blanks for marine work are cast almost to size, with a minimum of material left for finishing. The process consists in rotating specially constructed molds at a high rate of speed and pouring in the molten metal. The metal solidifies and forms the casting almost instantaneously. The assurance of homogeneous, close grained castings without flaws is claimed for the new process.

Submarine Signal Oscillator for Lightships

A NEW type submarine signal oscillator especially developed for lightship service was demonstrated at the Marine Exposition by the Submarine Signal Company, Boston, Mass. This new producer of submarine signals is a modified form of the Fessenden oscillator which is the most powerful generator of submarine signals ever devised. The new oscillator is much lighter than the Fessenden type, having substantially the same weight as the automatic bell now in service on light vessels.

The oscillator can be readily substituted for the bell on lightships and can be suspended from the davit now provided. The new equipment includes a rugged power plant which supplies the electrical energy required for the operation of the oscillator.

Naval Architects and Marine Engineers Hold Thirtieth Annual Convention During American Marine Week

President of Society Says Passage of Subsidy Bill Will Benefit Whole Country—Abstract of Papers and Discussion

THE thirtieth annual convention of the Society of Naval Architects and Marine Engineers, which was held this year in conjunction with the Marine Exposition at the Grand Central Palace, New York City, was opened at 10:30 A. M., Wednesday, November 8, by Walter M. McFarland, president of the society.

Secretary-Treasurer Daniel H. Cox in discussing the record of membership in the society stated that this membership, which shows a total of 1,631 in all grades, is excellent but that the society under conditions in the industry will do well if these figures are maintained. The increased membership as a result of abnormal shipbuilding activity during and for a short time after the war could not be maintained, as many of those who were engaged in shipbuilding operations who became members of the society have now returned to former occupations and, as a result, have resigned from membership. A number of new members have been admitted to the society, however, and applications are being received so that the coming year will probably show no decrease in the rolls of the society. The secretary's report showed the financial condition of the society to be very good, with a substantial increase in the endowment fund for the past year.

Election of Officers

The following officers were elected for the terms indicated:

Honorary Vice-President—Joseph H. Linnard.

Vice-Presidents (for term expiring October 31, 1925)—Albert P. Niblack, Richard M. Watt, Charles P. Wetherbee, Harvey D. Goulder.

Members of Council (for term expiring October 31, 1925)—Charles A. McAllister, Theodore E. Ferris, Hugo P. Frear, W. L. R. Emmet, J. Howland Gardner, William J. Davidson.

Associate Members of Council (for term expiring October 31, 1925)—Albert G. Smith, George D. Ali.

Executive Committee—Stevenson Taylor, W. L. Capps, Andrew Fletcher, F. L. Du Bosque, J. W. Powell, H. L. Ferguson, A. G. Smith.

Committee on Papers—F. L. Du Bosque, J. H. Gardner, H. L. Aldrich.

Secretary-Treasurer—Daniel H. Cox.

Assistant Secretary-Treasurer—Thomas J. Kain.

Abstract of President's Address

The question of supreme interest for all of us just now is the shipping bill. The vital element in this bill is the recognition of the duty of the Government to encourage the merchant marine, just as it endeavors to encourage other industries in the country by means of a protective tariff.

It is very gratifying to know that the earnest efforts made to educate the people of the country, particularly in the interior, have resulted in favorable action by Chambers of Commerce, Boards of Trade and other representatives of the citizenship of the interior. These will have very serious weight with their representatives in Congress.

The President has shown a strong personal interest in the matter and has gone on record as favoring Government help for our merchant marine. Under all these circumstances we have every reason to hope for favorable action by Congress with the resultant benefit to shipowners, shipbuilders and all who have any connection with the operation or building of ships. The passage of this bill will be of great benefit to the country at large by providing an outlet for the great amount of idle tonnage.

During the latter part of the war the class of vessels known as "transports" was designed of reasonably high speed and large capacity. The Government officials wisely called in help from some of the big operating companies in the design of these vessels, with the result that they were planned so as to be readily converted into passenger and freight steamers of the "liner" type. As a matter of fact, the end of the war came before any of them were finished, so they were completed for passenger and freight steamers. All of them are now in service and giving a very good account of themselves.

It is also very gratifying to note that a considerable number (about 150) of the vessels built at the three great fabricating yards have been in service almost continuously since they were built and reflect great credit on the yards for the record they have made.

For large powers and high speed vessels the geared turbine now seems an established favorite. In the case of cargo boats, such as the ones spoken of above, a great many installations have given complete satisfaction, and there is probably little doubt that with proper care and management they are entirely satisfactory. The reduced weight and greater economy due to this type of machinery certainly is a strong recommendation.

The very high thermal economy of the Diesel engine has brought it into very serious consideration in these days of the necessity to save at every point. A recent statement gives the number of motorships afloat at about 1,450, with about 180 under construction.

The use of oil as the fuel under boilers seems to increase steadily notwithstanding the predictions of a relatively early exhaustion of the oil fields. As long as the price is reasonable, the advantages of oil fuel are so many and so great that its increased use is to be expected.

The experience in the Navy with the electric drive on the new battleships has thus far been very satisfactory, a striking instance being that of the return trip of the *Maryland* from Rio de Janeiro to this city in September of this year, where, after steady running at nineteen knots for most of the trip, the speed was increased to the highest point, over 21 knots, for the last two days and everything worked admirably.

Another form of the electric drive where Diesel engines are used as the prime mover instead of steam engines is being tried out in some vessels of moderate size and power. The limitation of the Diesel engine to small powers per cylinder has, of course, thus far ruled it out of any installation of very powerful machinery.

Automatic Steering

By Elmer A. Sperry

Abstract

THE main points that influence holding a ship on her course under service conditions are the following:

1. The general characteristic of the ship, especially as to flow of water to the rudder and the disturbances of the water by nearby propellers.
2. The general effectiveness of the rudder, as such.
3. Whether the ship is light or loaded and, when light, if she is low at the stern with large areas forward exposed to wind effect.

If automatic steering is to be of the greatest value in controlling the ship's course, one of its paramount objects must be to suppress helm. This fact alone emphasizes the importance of a guiding element that is instantly and minutely responsive, to be employed as a base line so that the slightest departure from the course may be utilized to apply the correction.

No magnetic compass can ever be relied upon to do this. Within the last ten years ways and means have finally been developed that prove that in the gyro compass alone, with its instantaneous response to minute deviations of course, we have everything that is necessary to accomplish the purposes most effectively, even including the easing off, meeting, and full anticipation.

Of course, in the case of the gyro compass it is not the master which is used direct. The repeater follows the master with an accuracy of one-twelfth of a degree. This minute accuracy of the gyro compass repeater gives opportunity for automatic steering never before possible.

The embodiment of the mechanism for automatic steering has been developed in two types, which may be known as the "separate" system and the "unit" system. In each case the steering wheel is in its ordinary position on the bridge. Either of these systems can be employed with any telemotor system, but the "separate" type is preferred where a telemotor is not employed.

Operation of the Automatic Quartermaster

The instrument is capable of being set for response to different amounts of deviation from course. It has been employed practically for continuous steering of very large ships, and its performance is illustrated by conditions where the response is set as close as ten minutes of arc or 1/6 degree of departure from true course in azimuth. This operation is positive in its nature and through the closing of an electric contact calls into action the rudder operating mechanism, which simultaneously establishes the helm angle. This, in turn, operates a suitable follow-up mechanism by adjustment auxiliaries effecting the proper anticipation, and the helm eased off and returned or swung to its proper complementary angle.

In a typical "unit" system the gyro compass repeater, located at the top of the pedestal containing the automatic mechanism, is provided with a handle which is used to throw the automatic device in and out of gear with the steering wheel. Near the top of the pedestal is located a small tiller wheel by means of which all changes of course are set. Adjustments are provided for steering with the least helm according to different conditions of the ship and weather. Any standard telemotor may be employed with either the "unit" or "separate" type equipment.

Discussion

R. H. Rogers, of the General Electric Company, outlined the operation of the "wake" type of automatic steering which is being developed by the General Electric Company. This system operates with a base line formed by means of a drag towed aft. As the ship tends to move from the direct line made with the drag, electric contacts bring motors into function which, through a suitable mechanism, act upon the tiller. In comparing the two systems, Mr. Rogers brought out the fact that the gyro system, by means of the compass, holds the ship's axis to some course that is manually adjusted by estimation from time to time so as to make good the desired course, while the "wake" system works solely to the course being made good as indicated by the wake and allows the ship's axis to take automatically whatever headings are necessary to prevent deviation.

The importance of an adequate system of automatic steering cannot be too greatly emphasized when it is understood that even at a small helm angle the rudder causes a tremendous drag on the propelling engines. When unnecessary deviations from course are prevented the saving in engine power is correspondingly great.

Commander Herbert S. Howard, C. C., U. S. N., stated that the Bureau of Construction and Repair of the Navy Department is very much interested in this matter of automatic steering and would especially appreciate information on one point: In any system such as Sperry's in which the effort to return a ship to its course depends upon absolute deviation from that course, it would seem that the steering gear would keep the rudder over until the ship had regained the intended course. Her head would then, due to inertia, keep swinging beyond this course, which at once would cause the steering gear to move the rudder to the other side. In other words, with this type of automatic steering it would seem that the ship would have a sinuous course, the steering gear constantly hunting to keep the ship on a proper mean course. Although the preceding seems the natural deduction from what is understood of the arrangement of automatic steering gear described the records of performance do not show such a result. I should like to ask whether any means for correcting such a hunting action of the steering gear was employed or whether any such means is considered necessary.

In explanation of this point, C. B. Mills, chief engineer of the Sperry Gyroscope Company, who read the paper because of Mr. Sperry's absence in Japan, stated that ships in which an automatic steering device has been installed are too large to deviate very greatly from the course on account of hunting action, the tendency to yaw being stopped almost immediately by the gear. A marked saving in fuel with the use of this equipment has been noted. Records of the *Munargo* since the device has been in operation were cited as an example of economies possible with this gear.

Details of Naval Design from Jutland

By Commander Herbert S. Howard (C. C.). U. S. N.

Abstract

The many reports and discussions that have been published on the Battle of Jutland almost invariably have to do either with controversial points of strategy, movements of fleets and so forth, or major questions of design, particularly those comparative between British and German ships such as protection of vitals, turret magazine protection and so on.

There is a field, however, which comprises the performance of the different detail features of design of the naval ships in the battle which has so far never been discussed.

Of the ships sunk in the battle the *Queen Mary, Indefatigable, Invincible, Defence, Black Prince, Weisbaden* and *Pommern* were sunk as a result of complete explosion resulting from a salvo reaching a vital spot, or from a torpedo. The *Elbing* and also the *Turbulent* were rammed and sunk by German battleships.

These losses are generally eliminated then as involving major questions of design. We have left, then, of the total losses, on the British side one armored cruiser and seven destroyers, and on the German one battle cruiser, three light cruisers and five destroyers.

Fire might be taken as the principal source of danger to fighting ships and those aboard them. It brings in questions of inflammability of materials, fire systems, pipe lines and the menace of magazine explosion.

Most of the fires on the ships that were destroyed were entirely cordite fires, shells exploding in the vicinity of ammunition brought up and held ready to serve the secondary battery of large ships or the main battery of light cruisers and destroyers.

On destroyers in general it would appear that one or two direct hits by large shells were enough to put the ship entirely out of commission. The same result followed from a few salvos from a light cruiser. Under these conditions fires broke out at once. On oil burning destroyers severe oil fires should have occurred. This, however, does not seem to have been the case. Of the six destroyers from which we have accounts, on two only were there apparently oil fires, which in both were overcome quickly and effectually.

The deduction from this is that fuel oil does not seem the menace to light ships that it has at times been considered.

In dealing with fires in action the most serious difficulty was apparently the fact that in many cases the shell explosion which caused the fire completely wrecked the fire main and hoses in the vicinity. Besides putting the local fire-fighting equipment out of commission, water from the broken fire mains poured out on the decks and down below into engine rooms and other spaces where holes in decks or hatches existed. As a suggestion, it would seem that shut-off valves with distant control gear, together with long emergency lengths of hose kept below protection, are necessary where fire-main risers pierce armor decks.

Summing up, the fire menace proved to be in general less serious than had been expected.

Outside of the main engines and boilers of a naval vessel, probably the most important item of her machinery is the steering gear.

Of the several steering-gear jams which occurred during the battle the only one of which we have the probable details is in the case of the *Warspite*. In that ship both steering engines were secured on a vertical bulkhead in the engine room, and, as far as could be told, the bulkhead was strained by the bursting of a shell in the vicinity. The result was to throw the engine out of line and cause it to labor and run hot. When the order was then given suddenly to put the helm over, the engine could not handle the sudden load and the jam followed. Of the mishaps on the *Invincible* and *Chester* we have no details, but it may be inferred that they were due entirely to excessive speed and sudden changes of course.

These accidents bring forward the great importance of the steering gear and primarily the fact that trial and test conditions are not those of trial alone, but the very conditions which will be met with and quite possibly surpassed in battle. To avoid similar mishaps in the future the gear must first of all be so located as to be as free from the surrounding structure as possible, so that damage to that structure may not be communicated to the foundations of the gear. Also in the design there must be no weak points, while the operation must be as simple as possible to prevent mistakes in connecting up or disconnecting in the excitement of battle. Finally and most important, the trial condition tests must be accepted as the ordinary working condition of battle.

The accounts of the battle bring up many interesting points to do with damage to turrets, and particularly their great powers of resistance against attack and their ability to keep going in spite of damage.

Of the records consulted, these show direct hits causing damage on turrets of the *Lion, Tiger, Malaya,* and three turrets of the *Derfflinger*. Many other direct hits on both turrets and barbettes of various ships were received without either penetration or damage, but the hits of interest to examine are those where damage was received. Of the battle cruisers blown up, some at least may have received their death blows through penetration of turrets or barbettes and explosions within.

For many years armor gratings have been fitted in the openings of armor decks of warships, and for many years ballistic tests of these gratings have been carried out at various proving grounds to test the resisting power against major shell impact, or the impact of smaller shells representing fragments. While these tests have been of great importance, they have never represented the grating in its actual service condition.

On the *Warspite* a 12-inch shell struck the armor grating over one boiler room, but did not penetrate and was deflected upwards. The gratings were bent, but none broken, and apparently did all the work intended. Subsequently it was found that two other heavy hits had been received direct on the gratings, but in each case the shell was deflected. These reports indicate most clearly that reliance may be placed upon well-designed armor gratings.

After the battle the splinter nets below the gratings were found full of fragments, which confirms the opinion held as to the necessity for some additional protection below those gratings which receive the direct impact.

Rather an extraordinary thing occurred on the *Derfflinger*. In the middle of the battle the main central or plotting room suddenly filled with gas and had to be abandoned. It was found that the gas from the powder fires in the after turrets, and probably also from the ship's own guns, and from shells exploding aboard, had passed down the voice tubes to the central and temporarily put the station out of commission.

There was clearly shown here the danger from gas penetration through voice tubes, and in fact through any form of communication between compartments through which gases may pass.

Torpedo nets had been used both by English and Germans for many years before this battle, the former having, it is believed, been the first of all navies to introduce their use. As far as is known, the British removed them from their ships before Jutland. The Germans, however, went into battle with the nets on board stowed brailed up against the side in sea position.

After the battle Admiral Scheer stated that the nets on most of the ships were so damaged that it was impossible to remove them. In many cases they hung down in festoons, so that it was a wonder the propellers were not entangled.

It has been realized for some time that nets could be of service only to ships at anchor or at the slowest speed. Now we have it most clearly shown that they may become a grave menace to ships in battle. It would seem, then, that the case against the torpedo nets is complete.

Discussion

In a written discussion of this paper Professor William Hovgaard, of the Massachusetts Institute of Technology, offered as suggestions additional matters of detail naval design which might be studied and reported upon from the records of the battle of Jutland. The behavior of ships under the stress of war service, their suitability for the particular duty to which they are assigned, the damage which they suffer in action and their behavior under various forms of attack—all these points should be carefully studied and an attempt made to draw conclusions which may be useful in the design of new ships. The emphasis which the author of the paper lays on the importance of a robust and reliable steering gear as well as on its effective protection is most timely. The matter of danger from fires due to the ignition of powder charges is a point to which designers should give the most careful study. On other points not referred to in the paper it is safe to draw conclusions: During the war numerous cases occurred where towing of disabled warships was necessary, in some cases the life of the ships depending on the success of the operation. Adequate appliances for the efficient towing of large vessels should be supplied and the personnel trained in their use.

The importance of being able to stop leaks promptly and effectively in action was hardly realized prior to the war but improved appliances suitable for this should be provided and the service pertaining to their use carefully organized.

Most of the warships that went down during the war cap-

sized before they sank. To prevent or delay the process of capsizing and in general to right a ship quickly when she takes a list is of the greatest importance. Powerful means for righting the ship should be installed.

The serious consequences of salt water entering the feed tanks were demonstrated during the war. Feed water tanks should be so placed as to give them the best protection.

Rear Admiral A. P. Niblack, U. S. N., in discussing the fire hazard on board naval vessels in action, indicated that after practically every important naval engagement since the inception of the modern navies the question of fire on painted surfaces has been discussed. The present paper brings out very well the greatest points in fire hazard which are due mainly to cordite and other ammunition fires. In exhaustive tests by the Navy Department it has been impossible to ignite paint on steel surfaces, so this matter has finally been settled to the satisfaction of the constructors. Gases on board ship from shell explosions offer a very serious menace which must be guarded against by proper ventilation, the use of gas masks suitable for absorbing carbon monoxide and other means of protection. A great deal on the matter of ventilation is to be learned from the battle of Jutland. Since torpedo nets have never been used aboard ships of the United States Navy it is interesting to know that the decision of the Department not to equip our ships with them is borne out by the experience of the German ships during the battle of Jutland. One matter which should be investigated, for which practically no data are available, is the extent to which water coming aboard from shell explosions or other causes affects the fire control and other optical instruments of observation.

Commander Emory S. Land, C. C., U. S. N., suggested additional details of design to be studied, including watertight doors; flooding systems; drainage systems; communication systems, voice pipes, telephones and the like. Construction and operation of special equipment should be considered of equal importance; that is, when it is thought desirable to install equipment for special purposes on a vessel, such equipment should be used and the personnel trained in its operation.

Admiral D. W. Taylor, U. S. N., stated that during the battle both the offensive and defensive apparatus with which the ships were equipped functioned correctly and well. The question of fire hazard is probably the most important matter to be guarded against, cordite fires and apparatus for fighting them being the principal considerations under this head. Provisions should be made to protect the personnel against poison gases from shell explosions or other causes. The matter of torpedo nets was finally settled as a result of the German experience with them in the battle.

Stresses on Vessels of the Great Lakes Due to Waves of Varying Lengths and Heights

By Professor Herbert C. Sadler and Professor A. Lindblad

Abstract

At the last meeting of the committee on bulkheads and freeboard the question of including vessels on the Great Lakes in the assigning of freeboard came up. As no systematic investigation of the strength of this type of vessel had previously been made, it became necessary to carry out several strength calculations for the conditions met with in this region.

The study of waves encountered led to the conclusion that they seldom ran over 250 feet in length and that their heights appeared to be somewhat larger in proportion to their length than the usual ratio of 1:20.

Calculations were made for waves having the above characteristics on three types of vessels varying in length from 420 feet to 590 feet. The results are summarized in the form of bending moment factors and these will be included in the complete report to be published later in Marine Engineering and Shipping Age.

The conclusion drawn from the tests is that the lake freighters of today are for their service as strong as, if not stronger than, similar ocean-going types.

Discussion

In a written discussion on this subject David Arnott, deputy chief surveyor of the American Bureau of Shipping, brought out the fact that in the design of any ship's structure it is desirable, if undue waste in material is to be avoided, not only to know the maximum load to be carried but the most trying conditions as to distribution of load and the kind of seas likely to be met with in the service for which a vessel is intended. It is of importance that the authors have included in the paper data on waves encountered on the Great Lakes and the assertion that a wave of 350 feet in length and 20 feet high is the worst that need be considered. The large single deck bulk freighters used on the Great Lakes are a product of design to meet special conditions, the aim being to get the maximum deadweight on a restricted breadth and draft. The proportion of length to breadth given in the paper for a 580-foot vessel is considerably in excess of any merchant vessel engaged in overseas service. The big lake freighters are well designed for their intended service; that is, the carriage of ore, coal and grain on the Great Lakes. The longitudinal structural strength could be improved by carrying the wing tanks to the deck but this would reduce the deadweight carrying capacity for grain cargoes. One consideration which should not be lost sight of in making strength comparisons is the absence of serious deterioration through corrosive action in the steel hulls of lake vessels and, although a margin for corrosion is not evident in the strength standard of ocean-going vessels, it is there nevertheless so that on this ground alone lake vessels could have lighter scantlings and lower initial strength standard.

Admiral D. W. Taylor, U. S. N., in his discussion also mentioned the fact that the wave data on the Great Lakes gathered for this paper are very valuable. The fact is mentioned that the waves encountered are steeper than those of ocean waves but the depth of water actually is not the cause of this condition. The length of a wave seems to determine its steepness. The shorter ocean waves are, the steeper they become and this same fact would be true for waves on the Great Lakes which are comparatively short.

WEDNESDAY AFTERNOON SESSION

No important routine business came up at the opening of this session, the reading of papers being continued directly. The order of papers was somewhat changed in the morning session so that the following paper, which was originally scheduled for Wednesday morning, was read the first thing in the afternoon.

The Application of Dyson's Method to Propellers of Ocean-Going Merchant Vessels

By E. A. Stevens, Jr.

Abstract

In 1920 Admiral C. W. Dyson presented a paper on "The Problem of the Hull and Its Screw Propeller," in which a number of examples were given. As these were all naval vessels the writer has attempted to apply Dyson's method to

merchant vessel types and to compare the results with trial results on these vessels.

The problems may be divided into three groups. (1) Single screw vessels. (2) Vessels fitted with two or more screws—wing screws and struts. (3) Vessels with two or more screws—wing screws and bosses. Complete results of the comparisons will be published in detail in a later issue of MARINE ENGINEERING AND SHIPPING AGE. Seven are single screw ships, all of which with one exception have full lines, the block coefficients being over 0.77. Three are steel twin screw cargo and passenger ships or freighters. One is a moderate speed cargo and passenger vessel and the remaining two are high speed passenger vessels.

It is impossible to draw a general conclusion that will apply to all of these types of the comparative results obtained by Dyson's method of the actual trials as the complete tabular data contained in the paper must be studied for each individual case.

DISCUSSION

W. W. Smith, chief engineer of the Federal Shipbuilding Company, has found that because of the widely varying sea conditions encountered the 20 to 30 percent which the author adds to the ideal effective horsepower to obtain the effective horsepower at sea is a good allowance. No method of estimating, however, can predict the performance very closely for all conditions. The author is justified in his conclusion that the Dyson method is accurate for merchant type vessels, the trial results checking very closely with the estimated performance. Some of the differences noted are no doubt due to errors in measurement and the like. The analysis proved the reliability and accuracy of the Dyson method and so far as is known it is the only completely developed method for designing and analyzing propeller performance. Also it is the only one where the estimated performance checks closely with the trial results and where size, speed and cavitation are fully provided for.

In a written discussion Admiral Dyson brings out various points of difference with the author. He outlines the effect of spectacle frames and of the fin along the bottom of the ship when it is horizontal and at an angle with the hull. When the fin is horizontal or nearly so the basic slip of the hull is very much decreased from that which would exist when struts are used instead of spectacles. Also the K factor is reduced so that the new K factor equals the normal K factor of the hull of the one-seventh power. Where the fin is so located as to have no directive force upon water flowing to the screw, or to interfere with the water closing in around the hull, its effect on the basic slip and on K is nil. He goes on to discuss the conditions of the type 2 ship mentioned in the paper. When this ship is loaded down very deeply her estimated revolutions are considerably below those actually obtained. In such ships it is found better to make no correction as the ship is loaded down but to use for H the height from the base line to the upper limit of the stream line body Any increase in block above this has no effect on the revolutions but it does effect the value of K.

A Study of the Wake of Certain Models by Means of a Current Meter

By Professor E. M. Bragg

ABSTRACT

BY means of a current meter fitted with model propellers of varying diameters certain results of the effect of wake on models have been derived in this paper.

Tests were made on a 10-foot varnished plane for a series of four wax models with constant length of entrance and varying length of run, for a series of five wax models with constant length of run and varying length of entrance and for six wax models with no family relation. The speeds at which the tests were made ranged from about 140 feet per minute to 250 feet per minute. In the fine models the wake showed a slight tendency to decrease as the speed increased, while in the full models the wake was constant up to 200 feet per minute but at higher speeds there was found a marked increase in the wake due probably to the position of the stern wave.

This study of the wake of models, while not extensive enough to be conclusive, indicates that any complete system for determining wake values must include the following conditions: (1) The diameter of the screw relative to the draft of the ship. (2) The draft of the ship relative to the breadth of the ship. (3) The fore and aft position of the screw. (4) The transverse position of the screw. (5) The vertical position of the screw relative to the keel. (6) The vertical prismatic coefficient of the ship.

Some Experiments on Propeller Position and Propulsive Efficiency

By Rear Admiral D. W. Taylor, C. C., U. S. N.

This paper is published on page 785 of this issue.

DISCUSSION

W. W. Smith, chief engineer of the Federal Shipbuilding Company, had prepared written discussion on each of these papers which he read. In discussing the paper on "A Study of Wake," he stated that the paper was valuable for estimating the wake factor but for estimating propeller performance two other hull coefficients are required—the hull efficiency and the rotative efficiency. In making propeller estimates some engineers assume the hull and rotative efficiencies to be unity, but this assumption may introduce considerable errors in certain cases. The following elements would seem to require consideration in determining the hull coefficients of a vessel: Proportion and form of afterbody, size and location of propeller, and numerous others, including struts and bossings, cutting away of deadwood, rake of shafting, trim of vessel, location of rudder behind screw, speed length ratio and the like. Because of the large number of features involved it does not seem feasible to treat their application in an elementary form, it appearing more practical to divide all vessels into six or eight main groups, preparing for each group suitable data and coefficients for all practical variations. Referring to tests at various drafts it would be of value if the author would give prismatic coefficients of the afterbody for each draft. This paper emphasizes the difficulty of making estimates accurately from general data and the importance of self-propulsion tests which represent exactly the conditions to be met with. Further self-propelled model tests will not be truly valuable until they are proved reliable, and this will not be true until a number of test and trial results are compared, coordinated and published.

In speaking of the paper on "Propeller Experiments," Mr. Smith declared that he had sought after reliable data for estimating the effect of speed on the performance of propellers but had found none which seemed reliable except the charts given by Admiral Dyson, which data are only applicable where Dyson's method of estimating propellers is used. It would be desirable to have similar data for estimating full size propellers from model experiments. The large increase in hull efficiency brought out in the information contained in the paper, due to raising the propeller, is extraordinary, the gain in efficiency varying from 8 percent to 32 percent, with an average of 16 percent. The author's statement that a high location of propellers is desirable be-

cause of improved efficiency is contrary to the general idea that the lowest position is the most efficient. Admiral Dyson, for instance, gives an example in his book where lowering the propeller improves the efficiency greatly.

Mr. Smith ran tests on a small freighter driven by a Diesel engine to compare the propulsive efficiencies for high and low positions of the propeller and presents his findings in tabular form. In two cases a higher propulsive efficiency is obtained with the wheel in a lower position. This result, he states, is due to the higher slip ratio which occurs when the wheel is in the higher position; the higher slip ratio gives a lower propeller efficiency; also the pitch for the higher position must be less, which augments this effect.

Professor L. B. Chapman, of Lehigh University, in discussing the two papers together stated that when our knowledge of wake and the factors governing it has been carried a little further, propeller design will become simpler and more certain. From a large number of comparisons made between trials and the calculated results in Taylor's "Delta" diagrams when the wake could be closely estimated the check has been close indeed. The use of Taylor's charts is much simpler than any other methods and when proper wakes, thrust deductions and hull efficiencies are used the results are even more accurate.

Professor Bragg's suggestion of using a vertical prismatic coefficient is interesting, but the longitudinal coefficient (prismatic) of the afterbody is one of the most important factors. Difference in wake values between two of Professor Bragg's methods can hardly be charged to the difference in beam draft ratio. A comparison of these two methods on the same block coefficient and percentage of run shows a variation in wake of about 20 percent which is hard to explain.

THURSDAY MORNING SESSION

The second day's sessions of the thirtieth annual convention of the Society of Naval Architects and Maiine Engineers was opened by President McFarland at 10:30 A. M. November 8 in the Auditorium at the Marine Exposition. The great interest that was shown by the members in the first day's work was continued, even more being present than at the first sessions. No routine work was taken up at this point of the meeting.

Efficiency in the Operation of Steamships

By Captain Daniel A. J. Sullivan

This paper will be published in a later issue.

Discussion

In his remarks C. D. Mallory said that the salient features of ship operation had been covered very aptly in the paper by Captain Sullivan. Mr. Mallory's experience had been gained in the coastwise trade until 1917, after which time he was in charge of the Division of Operations of the Shipping Board until the end of the war. Since then he has been associated in operating twenty-three vessels on an intensive plan with a man who has had an extensive experience in foreign countries. He has come to the conclusion from intimate contact with foreign methods that with the high values in American ships and the correspondingly great interest and depreciation it is difficult for us to compete with other countries. Fuel, which is the biggest item of expense, by a proper study and application of efficiency in its use, will make competition easier. Oil for fuel is cheaper in this country than anywhere abroad. The United States Navy has learned more about its efficient use than any other navy in the world, and the Shipping Board is now making available this information to ship operators and engineers in the establishment of the naval school at Philadelphia. It is difficult to compare Shipping Board figures of operating costs with those of privately conducted concerns, since the latter are given a much wider latitude than in the case of the Shipping Board or ships allocated by the Shipping Board to private operators. The cost in general is higher for a Shipping Board vessel than for one privately operated.

James Donald seemed to think that the only proper way to compare operating conditions in this country with the ships of foreign countries was to prepare tables covering the same information as that given in the present paper. When the increased cost of wages in this country is included with items of first cost, depreciation and other high operating costs, little chance is left for American ships in competition with those of other powers.

Referring to the point made above, John L. Bogert presented a chart covering the items of the cost of operation of a fleet of one of the most successful foreign companies for a period of five years prior to the war. He particularly emphasized the item of fuel cost, which was given as 21.34 percent of the whole in 1911, when the fleet was composed mainly of steam driven vessels. At the end of five years, when practically all of the fleet consisted of motorships, the fuel cost had dropped to 16.58 percent. As in the case of railroads, ship operating costs must be reduced to the basis of cost per ton-mile. This matter has been taken up very satisfactorily on the lakes and can be applied to ships in the Atlantic trade. Comparisons on this basis could be made between all kinds of ships in a variety of service. Such a comparison could be established on a basis of Admiralty coefficients. Bearing out this statement, Mr. Bogert presented the comparison between a 370-foot ship and a 580-foot ship. In the former, 8 pounds of coal were consumed per 100-ton miles, while in the latter only 4.4 pounds of coal were consumed per 100-ton miles, making evident the fact that as the length of the ship goes up the fuel cost decreases quite rapidly.

Another contributor to the discussion familiar with the wage scales of Norway and Britain as well as with that of the United States, felt that other methods of reducing the cost of operation could be utilized without interfering with this item, which is not the most important. Efficient stevedoring, more rapid turn around, speedier loading, reduction of time at port and other items would contribute very greatly to the improvement in efficiency. The legislation governing tonnage dues, port charges, better contracts for towage and tug hire will aid in putting our ships on a competitive basis with those of other countries. From his experience with the carriage of oil this gentleman stated that, if a practical heating unit for liquefying the oil cargoes, especially crude oil, could be evolved, the motorship would solve many of the carrying problems of the oil companies.

E. H. Rigg, naval architect, New York Shipbuilding Corporation, referring to the cost of operation of vessels on the Great Lakes, brought out the point that lake vessels operate only during the summer months when the weather is good. A real comparison can hardly be made with ocean-going vessels, which must be used all the year around, in bad weather as well as good. Ships handicapped in this country by the high first cost will find it difficult to compete with more cheaply built foreign ships.

Professor Evers Burtner, of the Massachusetts Institute of Technology, in a written discussion offered a suggestion which has been found valuable by certain ship operating companies that a semi-graphical log sheet be used in maintaining records which act as a check and follow-up system to prevent unavoidable delays in turn round and the like. A summary is given in a sheet of this nature for the time required for different operations such as the time at port, time consumed at sea, demurrage repairs, speed in handling cargoes and the like.

G. E. Smith stated that since fuel and cargo handling

costs represent about 50 percent of operating costs, it is better to promote efficiency in the use of the former and improve the methods of handling cargoes than to interfere with the smaller item—wages. A custom in this country which increases construction costs materially is for the prospective ship buyer to specify very largely exactly what type of ship and equipment he will accept. In foreign countries the constructor uses his judgment in these matters and gives the operator a satisfactory ship for the purpose desired but without the many refinements and special features included in ships built in this country.

A 1,650 Horsepower Gasoline Fire Boat

By A. D. Stevens

Abstract

A DOZEN or more years ago the writer endeavored to develop a gasoline fire boat for the 7 odd miles of waterfront at Jacksonville. The boat was to have about 4,500 gallons per minute capacity, which could have been built at that period for less than $50,000. The use of gasoline on so large a scale did not appeal to the fire department at that time.

Four years ago, after the department had been converted to automobile trucks and motor fire engines, the fire-boat project was revived and the design of motor fire boat brought up to date.

The writer then submitted designs and specifications for the remodeling and conversion of *S. C. 145*, the boat the city had bought, which were accepted and ordered carried out under his directions as engineer in charge.

As a capacity of not less than 5,000 gallons per minute at 150 pounds pressure was desired and it was necessary to retain two of the three 220-horsepower propelling motors, it will be seen that there was no room to spare in a light wooden hull 110 feet by 14 feet by 8 feet.

In the forward 30 feet there are installed four 8-inch three-stage De Laval centrifugal fire pumps, each directly connected to a 300-horsepower "G. R. C." type Sterling eight-cylinder motor.

Since there are in the 50 feet by 14 feet machinery space forty-six gasoline motor cylinders aggregating 1,650 horsepower, the question of ventilation is of prime importance. This is provided for by two 2,000-cubic-foot-per-minute electric blowers, taking air through the after end of the steel trunk house and delivering it through ducts abreast of each propelling and pump engine.

In the 20-foot space used for the propelling machinery are two 220-horsepower six-cylinder air starting and reversing "Standard" motors, each driving a 48-inch diameter by 42-inch pitch three-bladed wheel of "Case" outward thrust pattern.

While the contract specifications of the pumping units called for a delivery (for each unit) of 1,250 gallons per minute at 150 pounds pressure and 1,100 gallons at 250 pounds, the tests at the builders' factory showed nearly 1,500 gallons at the lower pressure and 1,200 gallons at the higher. Tests at lower pressure gave a capacity of 1,750 gallons at 100 pounds, making a total of 7,000 gallons for the four pumps.

A special feature of this pump installation is that no compounding of the pumps is required to deliver the high pressure—250 pounds. The entire range of pressures is obtained by varying the speed of the engines.

Preliminary runs have developed a speed of 15 miles, with engines making 450 turns.

Summing up, the city of Jacksonville has secured, at a cost of less than $70,000, a fire boat of 7,000 gallons per minute capacity and a speed of 15 miles per hour, with a displacement of only 110 tons and a draft of 7 feet.

The Longitudinal Strength of Rigid Airships

By Professor William Hovgaard

Abstract

THE general strength of rigid airships is a problem akin to the corresponding one for ordinary ships. This paper results from a study of the subject carried out by the author when retained by the Navy Department in connection with the design of the rigid airship *ZR-1*.

The main purpose of the paper is to show that of two methods of calculation developed the bending method is essentially sound, and that with certain modifications it is reliable as a means of comparison between the strength of different airships. The shear method, on the other hand, in spite of its laboriousness, is incomplete and gives the correct results only when the longitudinals are at the apices of a regular polygon and when at the same time they are of uniform strength.

The study of the complex reactions in an airship is built up synthetically from a number of simple cases, beginning with rectangular panels. Following the study of the panel the theoretical effects of shearing and bending in the structure of an airship of regular polygonal section are examined and the conclusions are applied to an actual ship.

In conclusion the author states that:

1. A wire, so long as it is in tension, will transmit compressive forces as effectively as an elastic strut.

2. A wire may transmit tension and compression without any sensible change in its tensile stress.

3. The tension in the shear wire when a panel forms part of an airship structure is the sum or difference of that due to shearing deflection and that due to the direct pull or compression acting at the joints.

4. The horizontal forces, whether tensile or compressive, acting at a joint of a panel are directed partly along the longitudinal and partly along the wire (or wires) which meet at the joint, provided the wire is not slack.

5. The aggregate effect of a longitudinal and adjoining wires is the same as that of a girder of an area equal to the sum of that of the longitudinal and of the fictitious bars equivalent to the wires meeting at the joint.

6. Initial tension in the wires prevents or greatly reduces slackness and enables the counterwires to act as effective strength members.

7. The bending method can be safely applied with a fair degree of approximation to airships.

8. In applying the bending method to an actual airship, it is recommended to deal independently with each frame section.

9. The method of shears is fundamentally in error when used as the sole means of determining the general stresses in the structure of an airship by a process of summation.

Discussion

Commander Emory S. Land, C. C., U. S. N., Bureau of Aeronautics, presented a discussion on this paper prepared by Commander Jerome C. Hunsaker, C. C., U. S. N., Bureau of Aeronautics. In his own remarks prefacing the reading of this paper Commander Land stated that the *Z-R2* disaster, which occurred during the past year, developed the necessity for a more complete understanding of the stresses occurring in the structure of airships. Reports published in the press at the time of the disaster and subsequent to it seemed to indicate that the longitudinal strength of the keel member of the ship was insufficient, eye witnesses reporting that she seemed to open along the bottom. As a matter of fact, this statement was in error as the side members of the structure gave way first, the question being unimportant as to whether the top members or the keel failed after this.

In designs up to this time, the static forces on a ship were considered the important ones and it was thought that the allowances made for strength and the factors of safety incorporated in the design would take care of the aerodynamic forces. Investigation and the disasters noted in the past few months indicate that the aerodynamic forces under certain conditions may be even greater than the static forces and, as such, must be provided for in the original design of the strength members of the structure. The solution of problems in design are extremely difficult since they must take into account shearing, compression, tension and torsion forces.

The analogy made between the airship and the submarine is excellent and those who have aided in the solution of the problems encountered in the design of the latter should interest themselves and make available the results of their investigations in solving the airship problem.

The study of the stresses in rectangular panels, developed in the paper, forms an excellent basis for calculations. However, the actual problem is much more complicated where panels are bonded together, as in the airship structure.

Another point that must be considered in the investigation of actual ships is the fact that materials are more or less concentrated in weight at certain points, which is noticeably so at the keel. There is still a tremendous amount of work to be done in the laboratory, air tunnels, model basin and in the air on actual ships before the problem is completed.

Henry Goldmark, chairman of the committee of five on the investigation of the *Z-R2*, contributed valuable suggestions for the continuation of the work of investigating the subject and outlined the necessity of solving the problem of the forces acting on the ship, which are three-fold, the weight of the structure, the gas buoyancy and gas pressure and the aerodynamic forces which occur when the ship is being maneuvered. The theory of longitudinal strength is developed on the basis of beam action but the number of parts is so great that the method of least work is not usable. Approximate methods must be employed and checked so far as possible in model tests, theoretically, and finally checked by actual tests on ships.

Captain William J. Baxter, C. C., U. S. N., and Lieut.-Commander Harold E. Saunders, C. C., U. S. N., also contributed to the discussion of this paper.

Amendments to Constitution Adopted

For some years past several objectionable features have existed in the method of electing members to the Council of the society. The trouble has been carefully investigated by the officers of the society in the hope that the difficulties could be removed with the result that before the meetings this year the Council formulated changes to the constitution which were passed by the members at the Thursday meeting.

The wording of several sections of the constitution was changed but, as the meaning remains the same, these sections will not be included here. Those in which the revisions have altered the intent of the original sections are given below.

The principal provisions changed deal with membership of the Council and now read as follows:

ARTICLE IV—To read as follows:

1. *There shall be a Council composed of eighteen Members and nine Associates; and the President, Past Presidents, Honorary Vice-Presidents and Vice-Presidents shall also be Ex-Officio Council Members.*

2. The council *shall* meet at the call of the President *just prior to the annual general meeting of the Society and at such other times* as the interests of the Society may demand.

3. At all meetings of the Council *eight* members *thereof* shall constitute a quorum.

4. The term of office of Council Members shall be three years.

5. (a) *Prior to September First of each year the Executive Committee shall prepare ballots for filling the places of the Retiring Council Members.* The ballots shall contain the names of six *Members and three Associates of the Society* and shall be mailed as soon as practicable after September first of each year to all Members and Associates.

ARTICLE IV—Section 5, (b) to read:

(b) An independent nomination for Council Members may be made in writing by not less than thirty Members and Associates, of which number at least two-thirds must be Members; and if such nomination is received by the Secretary prior to September fifteenth, ballots shall then be prepared by him containing the names of those thus nominated and these ballots shall also be mailed to the membership.

(c) Each member may vote for not more than six Members and three Associates, and each Associate may vote for not more than three Associates to be Council Members.

The ballots shall be returned to the Secretary and canvassed by *the Council* at its meeting just prior to the annual general meeting of the Society; and the six Members of the Society and three Associates receiving the highest number of votes shall be declared elected Council Members.

(d) A vacancy in the office of Council *Member* shall be filled by the Council for the unexpired term.

As indicated, the provisions of Article IV, Section 5, allow for the election of exactly the number of individuals to the Council whose names appear on the ballot, thus avoiding the necessity of having the names of interested, active members of the society proposed on the ballot and then having these individuals eliminated in the election.

As noted above, the other changes in the constitution that were adopted are mainly in the wording, so that it does not seem necessary to include them in the report.

THURSDAY AFTERNOON SESSION

Colonel E. A. Simmons, president of the American Marine Association, was presented at the opening of the afternoon session by President McFarland. In his remarks Colonel Simmons cordially invited the naval architects to hold the professional meetings of the society in 1923 in conjunction with the exposition during Marine Week.

Following this, action was taken on ten names which had been proposed for election to the grade of member. Two associates were elected, one associate transferred to the grade of member and one junior to the grade of associate member.

Machinery and Trials of the Passenger Ships—American Legion Class

By Robert Warriner

Abstract

This paper gives the results of a model with rudder pulled in the tank at Washington, D. C., a self-propelled model run in the same tank, and a fairly good standardization trial of the completed ship at a draft corresponding to one of those at which the models were tested.

The vessels of the *American Legion* class are of the shelter-deck type, with straight stem and cruiser stern. The framing is constructed on the longitudinal system, except at the bossing and at the ends. The shell plating is arranged with in and out strakes, with overlap butts below the water line. The principal dimensions are: Length overall, 535 feet; breadth molded, 72 feet; designed load draft from base line, 30 feet; corresponding displacement (tons), 20,980.

The two propeller shafts are supported by cast steel spectacle frames and the framing and plating of the ship are bossed out from where the stern tube interesects the hull to the point where it attaches to the spectacle frame. The keel is of the flat type and the rudder balanced, with double steel plates over cast steel frame.

The engines are designed for 12,000 shaft horsepower on two shafts, and each shaft is driven by compound turbines through single-reduction gear with two pinions and main gear wheel in a single plane.

The screw propellers are of bronze, and are solid, three-bladed, 16 feet 6 inches diameter, 17 feet pitch, and each has 80.7 square feet of developed surface and 69.4 square feet of projected surface.

The lubricating oil is arranged on the gravity system with two pumps, two coolers and one gravity tank to each engine.

There is one V-shaped condenser to each engine with built steel shell, rolled brass tube plates and cast iron water ends.

The boiler installation consists of eight watertube boilers of the Yarrow type, arranged in two boiler rooms. The total heating surface in the eight boilers is 40,000 square feet. The boilers are oil fired, using mechanical burners and closed stokeholes.

The model for the vessels of this class was towed in the tank at Washington, D. C., under various conditions. The curves estimated from the tests show the shaft horsepower, revolutions per minute, and propulsive efficiency at 24 feet, 30 feet, and 36 feet draft.

The sea trials of the *President Pierce* were carried out at 24 feet draft, the lowest at which the models were tested and the easiest at which to ballast the ship, with the loads arranged so that at the high runs of the standardization trial, the draft would be as near as possible to the 24 feet and as near as possible to an even keel.

The plates given with the paper show the comparison of the model tests with the actual trial.

DISCUSSION

C. F. Bailey, engineering director, Newport News Shipbuilding and Dry Dock Company, gave an outline of the machinery details of the two *American Legion* class ships built by the Newport News Company which were somewhat different than those of similar ships built at other plants. For example, the main condensers on these two ships, the *President Cleveland* and the *President Jackson*, were reconstructed from condensers supplied by the Shipping Board. He went on to outline the full power trials of these two ships, the fuel consumption and the like, and to compare the results with the results given in the paper. He raised the question of the ability of the reduction gears to stand up under the continual overload to which they are being subjected in service.

E. H. Rigg, naval architect of the New York Shipbuilding Company, brought up the question of the discrepancy noted in the paper between the expected and the realized power. Several points of difference existed between the models and the ship as well as some differences between the propellers which no doubt would account for some of the error. The depth of water on the course can hardly be considered responsible because below 15 knots the effect of depth is hardly appreciable. The torsion meters used on the models may have read high as certain reports recently made would indicate.

Admiral C. W. Dyson, U. S. N., also noted the large discrepancy between the model basin trials and the actual trials of the vessel. The character of the hull, interference due to fins extending aft to the braces, and the like, probably had an influence on the matter.

Alfred J. C. Robertson, naval architect, Munson Steamship Line, gave details of operating results of the *American Legion* class ships in service. It is difficult, however, to eliminate actual conditions encountered in service that influence the operation of a ship so that comparisons may be made with trial or model test results.

Admiral D. W. Taylor, U. S. N., stated that this was not the first time that model basin results, when compared with full scale trials, have shown discrepancies. The fact, however, that the error reaches 12½ percent at 19 knots and 15 percent at lower speeds should be investigated. It has been found on exhaustive tests with naval vessels of all types that at speeds below 15 knots the depth of water on the course does not influence the run appreciably so that this factor can be disregarded in attempting to account for the great discrepancy noted in the paper. The question of fouling of the bottom might have a slight influence, the change of propeller speed on one vessel—the *President Pierce*—might have an effect; character of the hull, as brought out by Admiral Dyson, probably all influence the final result, the error being made up of small causes.

C. F. Bailey stated that it would be interesting to have data from the operators on the fireroom temperatures and the statement of the ability of the gears to stand up under heavy overloads which they are receiving in service.

Standardization as Affecting the Shipbuilding Industry in the United States

By E. H. Rigg

This paper is published on page 749 of this issue.

DISCUSSION

Hugo P. Frear, naval architect, Bethlehem Shipbuilding Corporation, Ltd., brought out the fact that the real standardized ship was one that could be built by several yards and which would be exactly similar in detail. If an individual builder in filling repeat orders could supply exactly the same type ship to the ship operator, such a ship would also be considered standard. During and immediately after the war, ships that may be considered standard were built in numbers at various plants but the chances are that occasion will never again arise when the necessity will exist for building ships in exactly the same way. It is hardly practicable to extend standardization beyond fittings and details in design and these considerations are not disregarded in this country. Shipbuilders and manufacturers develop standards of their own. The problem seems to be one of simplification rather than standardization. In his experience on standardization committees, a great deal of time and effort has been spent on standardizing the simplest fittings. However exhaustive the work will be, a start should be made. After standards are adopted shipbuilders and owners should follow them and give their support to the movement.

Professor William Hovgaard, Massachusetts Institute of Technology, stated that standardization can be carried to excess. The system should be elastic to take care of improvements. In Germany at the present time industries in general, including shipbuilding, are being subjected to the principles of standardization. Lists of standard fittings, machinery practices and the like are being published in technical journals from time to time outlining the progress of the work. The standards adopted are subject to modification as investigation and experience warrant changes. Once equipment is standardized, however, it should be used until it has been economically successful.

H. G. Smith did not feel that standardization would be carried too far. The two sections of ship standardization, as indicated in the paper, are the standardization of ship types and the standardization of parts. For the former, except in the event of war, the requirements for ships do not warrant quantity production. In the Navy, the standardization of parts, such as hatches, watertight doors, air ports and the like has been established, but when these standards have been submitted to the shipyards and put in effect improvements have made them practically of no use after a short time. He cited the example of a Chicago plant which was established for the manufacture of standard ship fittings. Jigs, fixtures and machinery were developed at great expense to turn out really excellent equipment but within a few months and before the original cost of the equipment had been returned from the products manufactured the

standards had changed so that the entire machinery and other equipment had to be discarded. The company failed on account of the lack of sufficient orders. This brings out the point that when standards are adopted they should be retained for a sufficient length of time to at least cover the cost of establishing the necessary production equipment and organization. In other words, changes in standards should be made slowly.

Admiral A. P. Niblack, U.S.N., in his remarks indicated that standardization is almost entirely an American accomplishment. The British, however, have done a great deal in this connection in shipbuilding. The standard design of the torpedo boat destroyers adopted by the U. S. Navy is one of the greatest examples of standardization on record. With the exception of machinery and slight changes of construction in the engine and boiler spaces, everything on all the destroyers is the same. Very few individuals realize the work which has been done in standardizing machinery and machine supplies at the naval experimental station, Annapolis, Md. The Navy will supply any of its facilities and information on the subject to aid the shipbuilders in trying to arrive at suitable standards. A lot of money can be saved in the industry by using standard fittings that are available on the open market rather than attempting to make them in the shipyards.

H. H. Schulze, of the Bethlehem Shipbuilding Corporation, Ltd., stated that standardization in shipbuilding would only become effective when the shipowner was willing to accept the standards developed by the shipbuilder. Shipowners, particularly large buyers, have their own standards which render the standards of the shipbuilder useless and consequently entail an additional cost for construction. When, however, the owner's requirements are not specified, standardization either of individual items, groups of items or methods of construction are of the greatest value. Nearly all old line shipbuilding companies have adopted standardization of items such as flanges, fittings, shackles, etc., but few have attempted the standardization of an entire system such as anchor gear, boat gear, rigging and the like. Where such entire groups have been standardized, they are of great assistance in the preparation of bids for the reason that without investigation on the part of the estimator he has immediately at hand the results, including weight and cost, of the best practice. Even steam engineering piping, complicated as it is, can be standardized to meet practically all conditions.

Selection of the Best Kind of Propelling Machinery

By J. L. Ackerson

Abstract

NEVER before has the marine engineering fraternity had so many different types of propelling machinery to select from, and there is no empirical formula which can be applied to help select the best type. Among the many factors to be considered are reliability (this is the most important single factor, for without reliability other advantages are very much discounted); economy in operation, initial cost, and weight.

The factors controlling reliability emanate from two different sources: (1) the owner through the selecting of competent personnel; and (2) the builder. No matter how well a machine has been designed and constructed, if placed in the hands of an incompetent operator it will become unreliable; and *vice versa*, no matter how good the operating engineer, if the proper factors have not been used in the design and care in the construction, then the machinery is again unreliable.

Economy in operation (that is, the fuel per horsepower) and initial cost usually bear a very close relation to each other, and it is only a question of figures to determine whether any particular type is worth the money as compared with any other type.

Weight is the least important except in the case of special types like shallow-draft boats, express-type steamers, warships, etc., because it is seldom that a ship is loaded down to a loaded draft mark, even when full of cargo. The subject matter of the paper is actually contained largely in tables comparing the following types of machinery and ships:

Geared turbines with Scotch boilers; geared turbines with watertube boilers; reciprocating steam engines with Scotch boilers; reciprocating steam engines with watertube boilers; Diesel engine 4-cycle; Diesel engine 2-cycle; for 5,000-ton freighter at 10½ knots; for 7,500-ton freighter at 11 knots; for 8,800-ton freighter at 10½ knots; for 10,000-ton freighter at 12½ knots; for 10,500-ton tanker at 10½ knots; for 17,000-ton displacement passenger ship at 15 knots.

The complete paper will be published in a later issue of Marine Engineering and Shipping Age.

Discussion

James C. Shaw, assistant to the chief engineer, William Cramp and Son's Ship and Engine Building Company, outlined comparative trials between different types of steam driven and Burmeister and Wain Diesel engine driven ships. He criticized the various comparisons in the paper and stated that basic data for the hulls and similar information should be included, so that comparisons might be more accurately drawn. Single screw motorships and twin screw steamships should not be compared nor where the reverse condition exists; that is, single screw steamships and twin screw motorships.

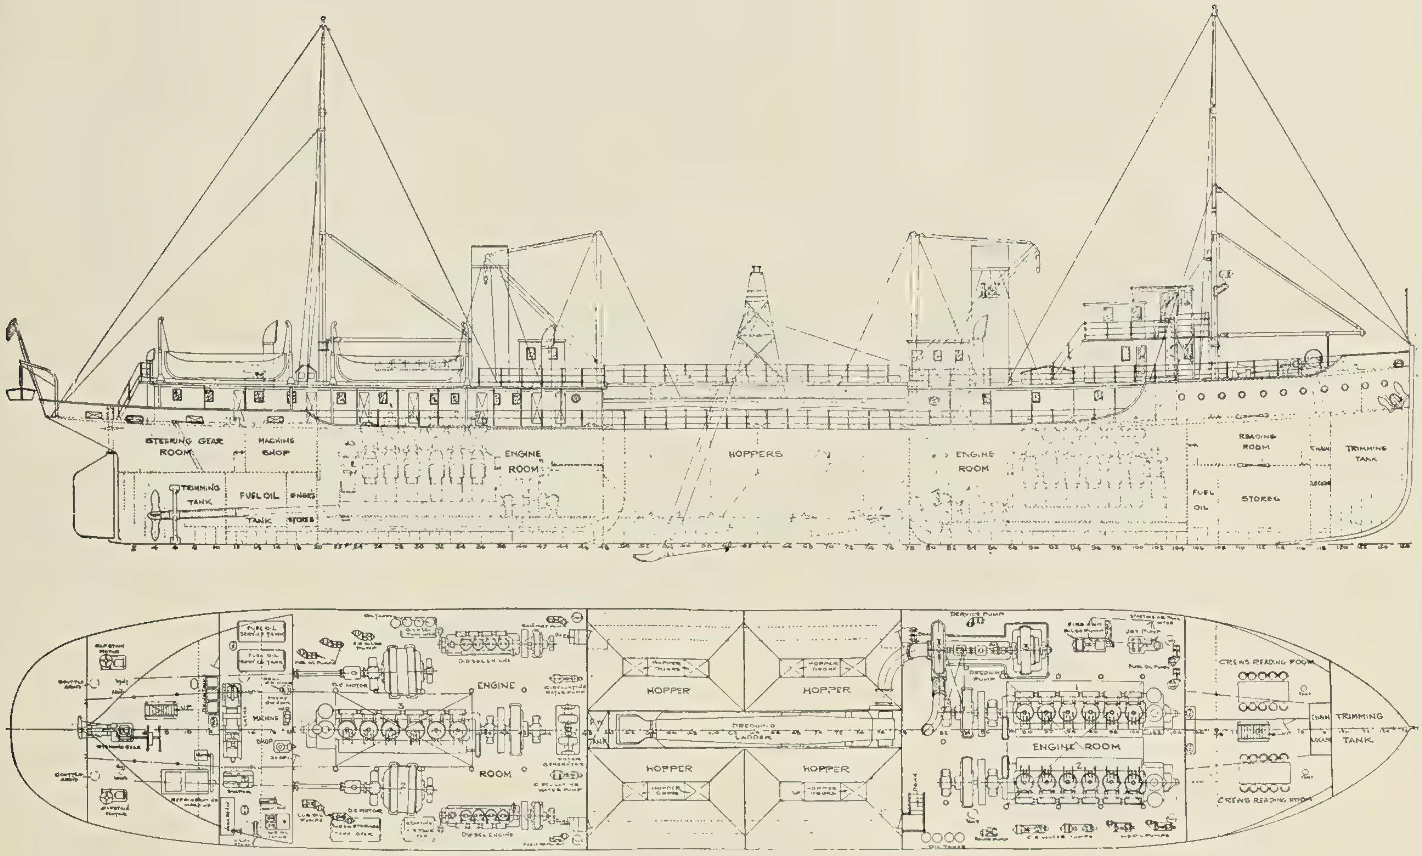
John L. Bogert cited examples of the low cost of motorship operation from data at hand. From data contained in the paper he pointed out that on a round trip voyage between this country and Scandinavia sufficient fuel could be carried in the double bottoms to fuel a motorship for the voyage and sell enough abroad to pay for the cost of fuel on the entire trip.

New Type of Low Pressure Expansion Joint

AT the recent Marine Show, held at the Grand Central Palace, New York, the Griscom-Russell Company, New York, exhibited one of their G-R type C expansion joints. In this joint the flanges are of cast iron and the expansion metal of copper. All sizes of the joint have a single corrugation. The special features of this device pointed out were the depth of the corrugation which is used, and the fact that the sides of the corrugation are actually parallel for at least one inch of their length. These joints are manufactured on a special patented machine and this exclusive patented method of rolling, it is claimed, insures a uniform thickness of copper after completion of the joint. Maintaining practically unchanged the original copper thickness permits the use of a thinner sheet than has previously been used, increases the flexibility of the joints and eliminates thinned spots.

The manufacturer states that these joints are guaranteed to compress ¼ inch axially when subject to a compressive force of 125 pounds per inch nominal diameter, and to be capable of distortion laterally ⅛ inch with a force of 125 pounds per inch nominal diameter. The joints are of the low pressure type and are designed particularly for use on steam lines between the turbine and the condenser.

This improvement in expansion joint design is the result of months of experimentation and development by the manufacturers.



Profile and Hold Plan of Army Diesel-Electric Hopper Dredges

New U. S. Army Dredges to Be Completely Electrified

Power for Propulsion, Dredging and Auxiliary Purposes Provided by Three 1,000-Horsepower Diesel-Electric Generator Sets

An excellent illustration of the growing tendency to use electricity on shipboard is provided by the four hopper dredges which were designed by the United States Engineer Corps and are being built by the Sun Shipbuilding Company, Chester, Pa. On these vessels electricity is to be used for every possible purpose. It will propel the ships and steer them; it will operate the dredging pumps and all of the auxiliary machinery; it will supply heat in winter, cool breezes in summer, and ventilation at all times; and it will furnish hot water and do the cooking. Quite literally, there will be no fires of any kind aboard these dredges, save those in the cigars and pipes of the officers and crews.

These dredges are intended for harbor work and are to be thoroughly seaworthy. They are to have a length overall of 268 feet 5 inches; molded breadth of 46 feet; draft of 19 feet 6 inches; and total deadweight carrying capacity of about 2,000 tons. Midships in each vessel there is a well 56 feet long and 7 feet wide in which the suction pipe of the dredging pump is suspended. This pipe is 26 inches in diameter and 50 feet long. It is carried by a ladder and is so arranged that the intake end can be lowered into the silt to be removed. The dredging pump is of the 26-inch, volute-centrifugal, single-suction type. It discharges into hoppers located on either side of the well which have a total capacity of 1,250 cubic yards per ship. When the hoppers are filled, the dredge proceeds to the open sea and empties them by means of doors in the bottoms.

The main engines of each dredge consist of three 1,000 brake horsepower McIntosh & Seymour Diesel engines, each of which will be directly connected to a 700-kilowatt, 500-volt, direct-current Westinghouse electric generator of 150 revolutions per minute. These generators will furnish the power for operating the propellers and the dredging pump.

Each dredge is to be propelled by twin screws, and each propeller is to be direct connected to an 800-horsepower, 480-volt, direct-current Westinghouse motor of the double-armature type. The speed of these motors can be varied from 90 to 110 revolutions per minute.

The main dredge pump is to be driven by a 750-horsepower, 480-volt, direct-current Westinghouse motor, which has a speed variation of from 135 to 160 revolutions per minute.

The windings of both generators and motors will be impregnated with moisture-resisting compounds and enclosed by protecting covers. Forced ventilation will be provided by small motor-driven blowers.

Advantages of the Drive

Four special advantages will be gained by the use of Diesel-electric drive on these dredges.

Economy of Operation.—Because of the fuel economy of the Diesel engine, the operating cost of these dredges will be less than if steam drive were employed.

Freedom as to the Arrangement of the Machinery.—Were the propellers and the pumps of these dredges driven by direct-connected engines of any kind, the positions of all of

these machines would be definitely fixed. In designing the vessels, therefore, the designer would be compelled to start with this machinery layout and adapt the dredging apparatus to it as best he could. With Diesel-electric drive, however, much greater freedom is given the designer, because the engine-generator units are not fixed as to location but can be placed almost anywhere on the vessel.

A study of the plans of these dredges shows that advantage has been taken of this fact. There are two engine rooms, one forward of the ladder well and containing the dredge pump, and the other aft of the well and containing the propeller motors. Only one engine-generator unit is placed in the aft engine room, while the other two are placed in the forward engine room at a considerable distance from the propellers and, moreover, off center. In other words, these vessels were designed primarily as dredges, and the machinery was fitted in wherever it could most conveniently go. Therefore, even if everything else were equal, these dredges will be more efficient *as dredges* than they would be, if the direct drive were used.

Interchangeability of Generators.—Were each propeller and the main dredge pump of these dredges driven by its own individual engine, the breaking down of any one of the engines would badly cripple the vessel on which the accident happened. Either the dredge pump would be out of commission, or the vessel would have to propel itself awkwardly with a single screw. But with the Diesel-electric drive the utmost flexibility of connections is permitted. The switching arrangements provide for seven different combinations; namely, any generator to any motor; any one of the three generators to both propeller motors; and either of two generators to the dredge motor. Consequently, the breaking down of one engine would not seriously interfere with the operation of either the dredge or the propellers, and even if two engines were down, the vessel could still be propelled without difficulty.

A special switching device has been designed to effect these various connections. This device is mounted on the main switchboard and consists of a group of contactors opened and closed by a system of cams which are operated by a handwheel. There are eight different positions for the handwheel, corresponding to the seven combinations and a point where all circuits are opened. The handwheel can be locked in each position, and cannot be moved until all circuits are open, so that heavy main-line currents are not broken by the contactors.

Ease of Maneuvering.—In accordance with standard Diesel-electric practice, all movements of the propeller motor are to be controlled by two small rheostats (one for each motor) located in the pilot house with duplicates in the engine room. The complete control of the vessel, therefore, will be in the hands of the navigating officer, which is very desirable because of the constant maneuvering that is required of these dredges.

Auxiliary Machinery

Among the motor-driven auxiliary machines on each dredge are 25 auxiliary pumps, 2 air compressors, the steering gear, a windlass, 2 capstans, 2 winches, 2 hopper-door openers, the ladder hoist and the refrigerating machine. Most of the motors for these machines are to be of the ordinary open standard type, with impregnated windings and non-corrodible small parts. The winch motors and the hopper-door motor, which are to be mounted on the open deck, are to be of the cast steel, watertight design which has proved so successful on the motorships *William Penn* and *Californian*.

The control of almost all of these motors is to be of the automatic type; that is, the operator merely pushes buttons or turns a light master switch to start, stop and control the speed of the motor. The use of controllers of this kind insures the maximum ease and safety of operation and is in line with modern industrial practice.

Included in the electrical equipment of each dredge are to be 88 electric room heaters, ranging from 1,000 to 5,000 watts each in capacity, three 5,000-watt water-heaters for each hot water boiler, 23 electric fans and two electric ranges of 22 kilowatts capacity each.

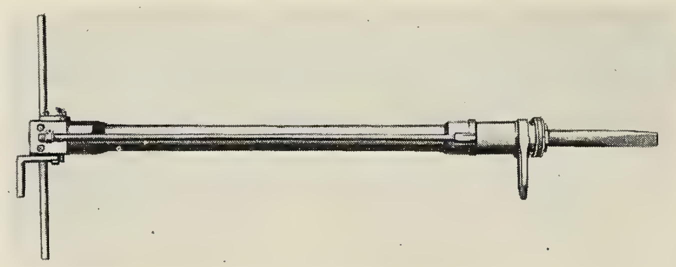
The auxiliaries will be supplied with current from two auxiliary Diesel engine driven 150-kilowatt, 250-volt generators, and also from a 150-horsepower motor-generator set which can be supplied with power from the generator normally used to operate the dredge pump motor.

All of the electrical equipment on these dredges is being supplied by the Westinghouse Electric and Manufacturing Company.

New Type Rivet Cutter

On the principle that when cutting rivets, a number of comparatively light, rapid blows cause more vibration and therefore more distortion of steel plates than a few intermittent, heavy blows, the Chicago Pneumatic Tool Company, New York, has designed and manufactured a new type of rivet cutter known as the "Boyer Superior."

Its construction is described as consisting of a dead handle, a throttle handle of the crank design, a throttle valve of the taper type, a back head screwed onto the cylinder and secured by a locking device, a cushion chamber in the rear end



Improved Rivet Cutter

of the cylinder, a cylinder of seamless steel tubing, a bypass from back to front head, a non-removable electrically welded front head, square coiled spring buffer, adjustable chisel lock, hand hold of the spade handle type and chisel.

To operate, the throttle handle is moved in a line parallel with the cylinder. Each forward and return stroke of the piston is hand controlled. About four blows, requiring approximately 10 to 15 seconds, are said to be required to cut off the head of a ¾-inch rivet. Two men are required to operate the machine. It can be used wherever rivets are to be cut.

Mechanical Engineers' Annual Meeting.—The annual meeting of the American Society of Mechanical Engineers will be held at 29 West 39th street, New York City, December 4 to 7. On Monday, December 4, there will be public hearings on the Boiler Code and a joint session with the American Society of Refrigerating Engineers. On Tuesday there will be sessions covering management, machine shop practice, materials handling, training for the industries, research, steam tables, a public hearing on power test codes and a general session. On Wednesday the general session will be continued and there will be sessions covering fuels and railroad practice. In the evening there will be a joint session with the American Economic Association. On Thursday are scheduled sessions on power, standardization, safety engineering, ordnance, aeronautics and forest products.

Shipping Board Establishes Standard for Efficient Performance of Its 502-Foot Passenger Vessels

Fuel Conservation Committee Adopts Mileage Traveled Per Ton of Fuel, Based on Average Conditions, As the Standard

THE campaign of the United States Shipping Board to increase the efficiency of operation in the engine department, and thereby reduce the fuel bill, of the vessels operated by the Board is being carried out by the workings of the Fuel Conservation Committee, appointed by Vice-President Joseph E. Sheedy of the United States Shipping Board Emergency Fleet Corporation, from the various engineering societies and organizations. The members of this committee are:

Captain C. A. McAllister, chairman; Commander R. D. Gatewood (C. C.), U. S. N.; E. H. Peabody, D. M. Myers, Maurice Healey, Major George M. Talbot, F. B. Webster, H. B. Taylor, C. J. Jefferson, E. A. Stevens and C. H. Jack.

Many engineering problems of a most interesting nature to the marine world have already arisen. Chief among these problems has been that of establishing a standard of performance that is applicable to the every day operation of a fleet made up of several score types of vessels, this standard to be reasonably correct for average conditions and not to be based on the results obtained on any single short trial trip performance.

To solve this problem, the active fleet of the United States

Grand average	22′ 7½″	100.8	13.9	89.6	600.9	3.74	4.06	0.921

Shipping Board has been cataloged under a minimum number of classes, the factors affecting this cataloging being: type of boilers, type of driving machinery, hull design, kind of fuel, type of auxiliaries and the propeller design.

The next step in the problem was to establish a factor of performance which would be subjected to the least variable and which could be determined the most accurately. The ideal factor to use would be the British thermal units per indicated horsepower relation, but this could not be used as the collection of the necessary data to utilize such a standard would be well nigh impossible and in order to obtain data which would give even reasonable approximation of the actual value, the cost would offset the gains made in the efficiencies of performance, which is a frequent fault of efficiency engineers and is being carefully avoided by the Fuel Conservation Section.

The final standard adopted as the one least subject to variables and which could be applied most accurately and readily to actual performance is the mileage per ton of fuel.

The standardization curves are based on effective horsepower curves made from tests on the tank models with corrections made for average weather, deep sea and average bottom condition, the horsepower at various speeds and drafts having been determined. The fuel consumption was computed using a variable fuel per indicated horsepower value, depending upon the percentage of auxiliary load to main engine power and the varying water rates of main engine at different percentages of power developed with the varying evaporation factor based upon percentage of the boiler power developed. The accompanying curves show the standards developed for the 502-foot passenger vessels of the *President Polk* (ex—*Granite State*) class.

Standards Developed for 502-foot Passenger Vessels of the President Polk Class, Built by the New York Shipbuilding Corporation

The principal characteristics are as follows:

Length between perpendiculars	502 feet 0 inches
Breadth	62 feet 0 inches
Depth	42 feet 0 inches
Loaded draft	32 feet 3 inches
Deadweight tonnage	13,000
Speed (knots)	14.5
Engines	2-4-cylinder triple expansion 7,000 horsepower
Propellers	2
Boilers	6 Scotch
Heating surface (each)	2,666 square feet
Built by	New York Shipbuilding Corporation, Camden, N. J.

The curves are applicable to average deep sea and average weather conditions, so with extraordinarily smooth seas a plus correction must be applied while with very heavy seas a minus correction is used. The curves do not represent the maximum efficiencies that can be produced by the vessels of this class. They do, however, give a possible performance standard which all of the vessels can attain without extraordinary modifications in their equipment.

The tabulated actual performances of seven of these vessels for a number of voyages show how these curves can be used to determine the efficiency of performance. It will be noted that the average efficiency for these vessels is 92 percent while the best showing is 105 percent and the poorest performance is 80.6 percent.

This variance in efficiency is traceable to the condition of furnace fittings, condition of steam and water end of auxiliaries, condition of main engine piston and cylinders, methods of operation and other like causes, all of which can and will be corrected and the results of the methods employed in making these corrections can be readily checked by referring the performance to the standards shown on the curves.

This is the first class of vessels for which these standards have been developed by the Fuel Conservation Committee and represents but the beginning of a large task. It is, however, a definite step along the lines of real efficiency engineering and a constructive effort towards the permanency of the United States merchant marine.

South American Mail Subsidy Continued.—The ten-year contract between the Government of the Union of South Africa and the Castle-Vail Steamship Company for transporting weekly the mails in both directions between Southampton and Cape Town, which expired September 30, 1922, has been extended for two years.

How Propeller Position Affects Propulsive Efficiency

Paper read at annual meeting of Society of Naval Architects and Marine Engineers by Rear Admiral D. W. Taylor (C. C.), U. S. N., honorary vice-president of the Society, dean of American naval architects and former Chief Constructor of the United States Navy, giving results of Model Basin experiments on propeller position and propulsive efficiency for single-screw low-speed vessels.

AFTER publication of results of years of Model Basin experimentation, the naval architect and marine engineer can now determine in advance with reasonable accuracy, for normal forms, the effective horsepower of a ship and the dimensions and proportions of a propeller which would propel the ship with high efficiency, if it were Froude's phantom ship, which has the resistance of the actual ship but is assumed not to disturb the water.

But we have to deal with actual ships, and the reactions between ship and propeller are very complicated phenomena. The wake of the ship of course affects the action of the propeller, and the suction of the propeller adds to the resistance of the ship. The thrust deduction is always positive, *i. e.*, the thrust is greater than the resistance of the ship without the propeller. Nearly always, however, the wake is also positive, which tends to increase the efficiency of propulsion. We generally and conveniently characterize the net results of the opposing factors as hull efficiency. If this is unity, the power required to propel the actual ship is the same as if it were Froude's phantom ship, while a hull efficiency greater than unity means that we can get along with less power and vice versa.

Factors Affecting Hull Efficiency

A brief enumeration of the factors affecting hull efficiency indicates the difficulties of dealing with it accurately. Considering the hull, it is affected by dimension and shape, but more particularly by the fullness and shape of the after body. A "V" stern, for instance, will show a somewhat different wake from a "U" stern, and the thrust deductions upon it will not be quite the same.

Considering the propeller alone, the hull efficiency must be somewhat dependent upon its dimensions and proportions, blade area, blade thickness, shape of blade, etc.

Considering the combination of ship and propellers, the hull efficiency must be affected by the number and locations of the propellers. For a single-screw ship, the propeller position may be varied vertically and longitudinally. For vessels of two or more screws, locations may be varied transversely for side screws.

For high-speed ships the hull efficiency must be affected by speed.

Probably of the many factors involved, those of location are most in need of systematic investigation because in many practical cases there is some choice of location and we would like to know whether we can gain anything by making a proper choice, and also whether we could gain by so shaping our designs as to permit a favorable location without counterbalancing loss in other respects.

Location of Propeller for Single-Screw Low-Speed Vessel

The experiments which are the subject of this paper, recently made at the United States Model Basin, deal with the question of location for a single-screw low-speed vessel. They were initiated while I was chief constructor, and my successor, Chief Constructor Beuret, has kindly permitted their publication. The lines of the model used are shown in Fig. 1, and it will be observed that it is of rather a full type. It is hoped that at some future time, if an opportunity permits, the stern lines may be further fined and the experiments repeated.

Fig. 2 shows the three model propellers used. With the possible exception of 571, they were smaller than would be used for the actual ship in practice. This permits a maximum vertical change of position and insures that the propellers work at a high real slip and cover a wide variation of slip. Fig. 3, supplemented by Table I, shows the test positions for the propellers, three positions at the upper level, three at the lower level, and three propellers used in each position. It was then necessary to make eighteen sets of runs at each speed of model. Figs. 4, 5 and 6 show the usual characteristic curves of the three propellers as tested apart from the model. In making the tests with the pro-

pellers attached, the model was self-propelled at the desired speed, the torque and thrust being determined. From this there were deduced the two quantities w and t. The average speed of the wake over the propeller area is the speed of the ship multiplied by w, the wake fraction. The thrust deduction coefficient t is a quantity such that the actual thrust multiplied by the factor $(1 - t)$ is the resistance of the vessel without the propeller. The hull efficiency, as usual, is expressed by $1 - t/1 - w$.

Tests were made at a number of speeds extending from 2 knots speed of the model to 2.8 knots speed of the model, but the variations in the results with speed were not sufficiently marked with this model to be significant.

Results of Tests

Fig. 7 shows the reduced results in the small tables, each located with its center in the same position relative to the ship (indicated by the stern outline) as the propeller centers. As is to be expected from a single set of experiments on such a small scale, there are some inconsistencies in the results. It would require other experiments enabling cross-fairing to eliminate them. Broadly speaking, however, Fig. 7, which is confirmed by the results at other speeds, shows that the dimensions and proportions of the screw had a minor effect upon the hull efficiency. The very wide variation of slip resulting from the variation in screw dimensions had

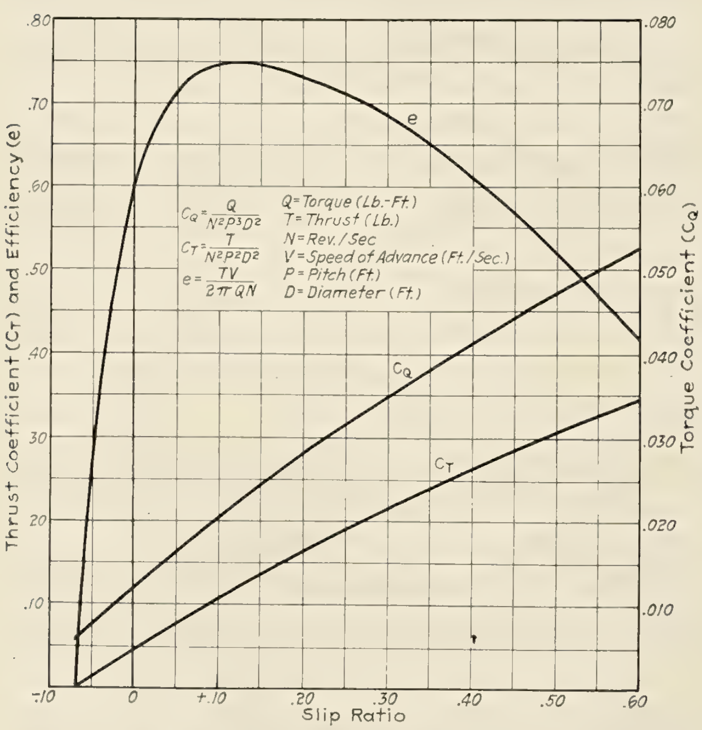

Fig. 4.—Propeller No. 570, Coefficients and Efficiency

comparatively little effect. At each level, as the screw was placed further and further aft, the wake fraction and thrust deduction coefficient fell off steadily. These changes rather neutralize one another, so that in this case it does not appear there was any material gain by variation in the fore and aft position of the propeller. When, however, we consider the vertical variation, it is another story. For the upper locations the hull efficiency is consistently higher than for the lower, the gains being somewhere between 15 and 20 percent. This is in accordance with what might be expected from theoretical considerations.

It would seem that the naval architect is confronted by another case of conflicting tendencies where a compromise is necessary. For the majority of vessels virtually all considerations, except that of hull efficiency, dictate the lowest practicable position of the propeller. Doubtless in sea-going vessels with reciprocating engines the considerations dictating maximum submergence must preponderate, but for vessels with types of propelling machinery not subject to racing in heavy weather, and for vessels primarily for smooth-water service, we cannot ignore the fact that the higher the propeller location the greater the hull efficiency and hence possible efficiency of propulsion.

I say "possible" efficiency of propulsion because to take full advantage of the greater wake associated with high propeller locations, the high propeller should be of somewhat greater diameter than the low propeller for such a vessel as Model 2441.

In conclusion, I should like to record my appreciation of the assistance in the preparation of this paper given me by the Model Basin Staff, headed by Captain Eggert (C. C.), U. S. N., in charge of the Model Basin. It was necessary to interfere with other important work to get in these experiments. I hope further experiments along this line, planned at the Model Basin, may appear in the *Transactions* of the Society in due time.

Correction

IN connection with the article on "Line Shafts for Marine Internal Combustion Engines," by Joseph Hecking, in the November issue of MARINE ENGINEERING AND SHIPPING AGE, the attention of our readers is directed to a printer's error in the formulæ Nos. 11 and 12 on page 718.

In both formulæ the value (1 + C) should be added, so that the formulæ will read, respectively, as follows:

$$d = .683 \sqrt[3]{\frac{p D^2 S N}{5{,}000} (1 + C)} \qquad (11)$$

$$d = .861 \sqrt[3]{\frac{p D^2 S N}{5{,}000} (1 + C)} \qquad (12)$$

Freight and Passenger Vessel for Florida Service

Mobile Shipyard Building Wooden Motorship, Reinforced with Steel, Designed by Cox and Stevens for Adams Boat Line

THERE is now under construction at the Murnan Shipbuilding Corporation, Mobile, Ala., a new freight and passenger boat equipped with oil engines which is being built from the designs of Cox and Stevens, naval architects, New York, and under their supervision for the Adams Boat Line, Inc. This company does business between Tampa, St. Petersburg, Manatee River and Sarasota Bay towns. The new boat, however, will be used on the run between Tampa, St. Petersburg, Palmetto and Bradentown.

The general type of this new boat, which will be called the *Jeannette Scott,* is somewhat of a departure, the hull being of wood reinforced with steel, and the machinery of the heavy oil type. The dimensions are as follows:

Length overall	120 feet
Length on waterline	114 feet
Beam	25 feet 6 inches
Depth	8 feet
Draft	4 feet 10 inches

On the main deck, in addition to the usual open freight space forward, there is an enclosed freight deck amidships, while aft are the dining room and galley. The quarters for the engineer, purser's office and the men's toilet are also on this deck.

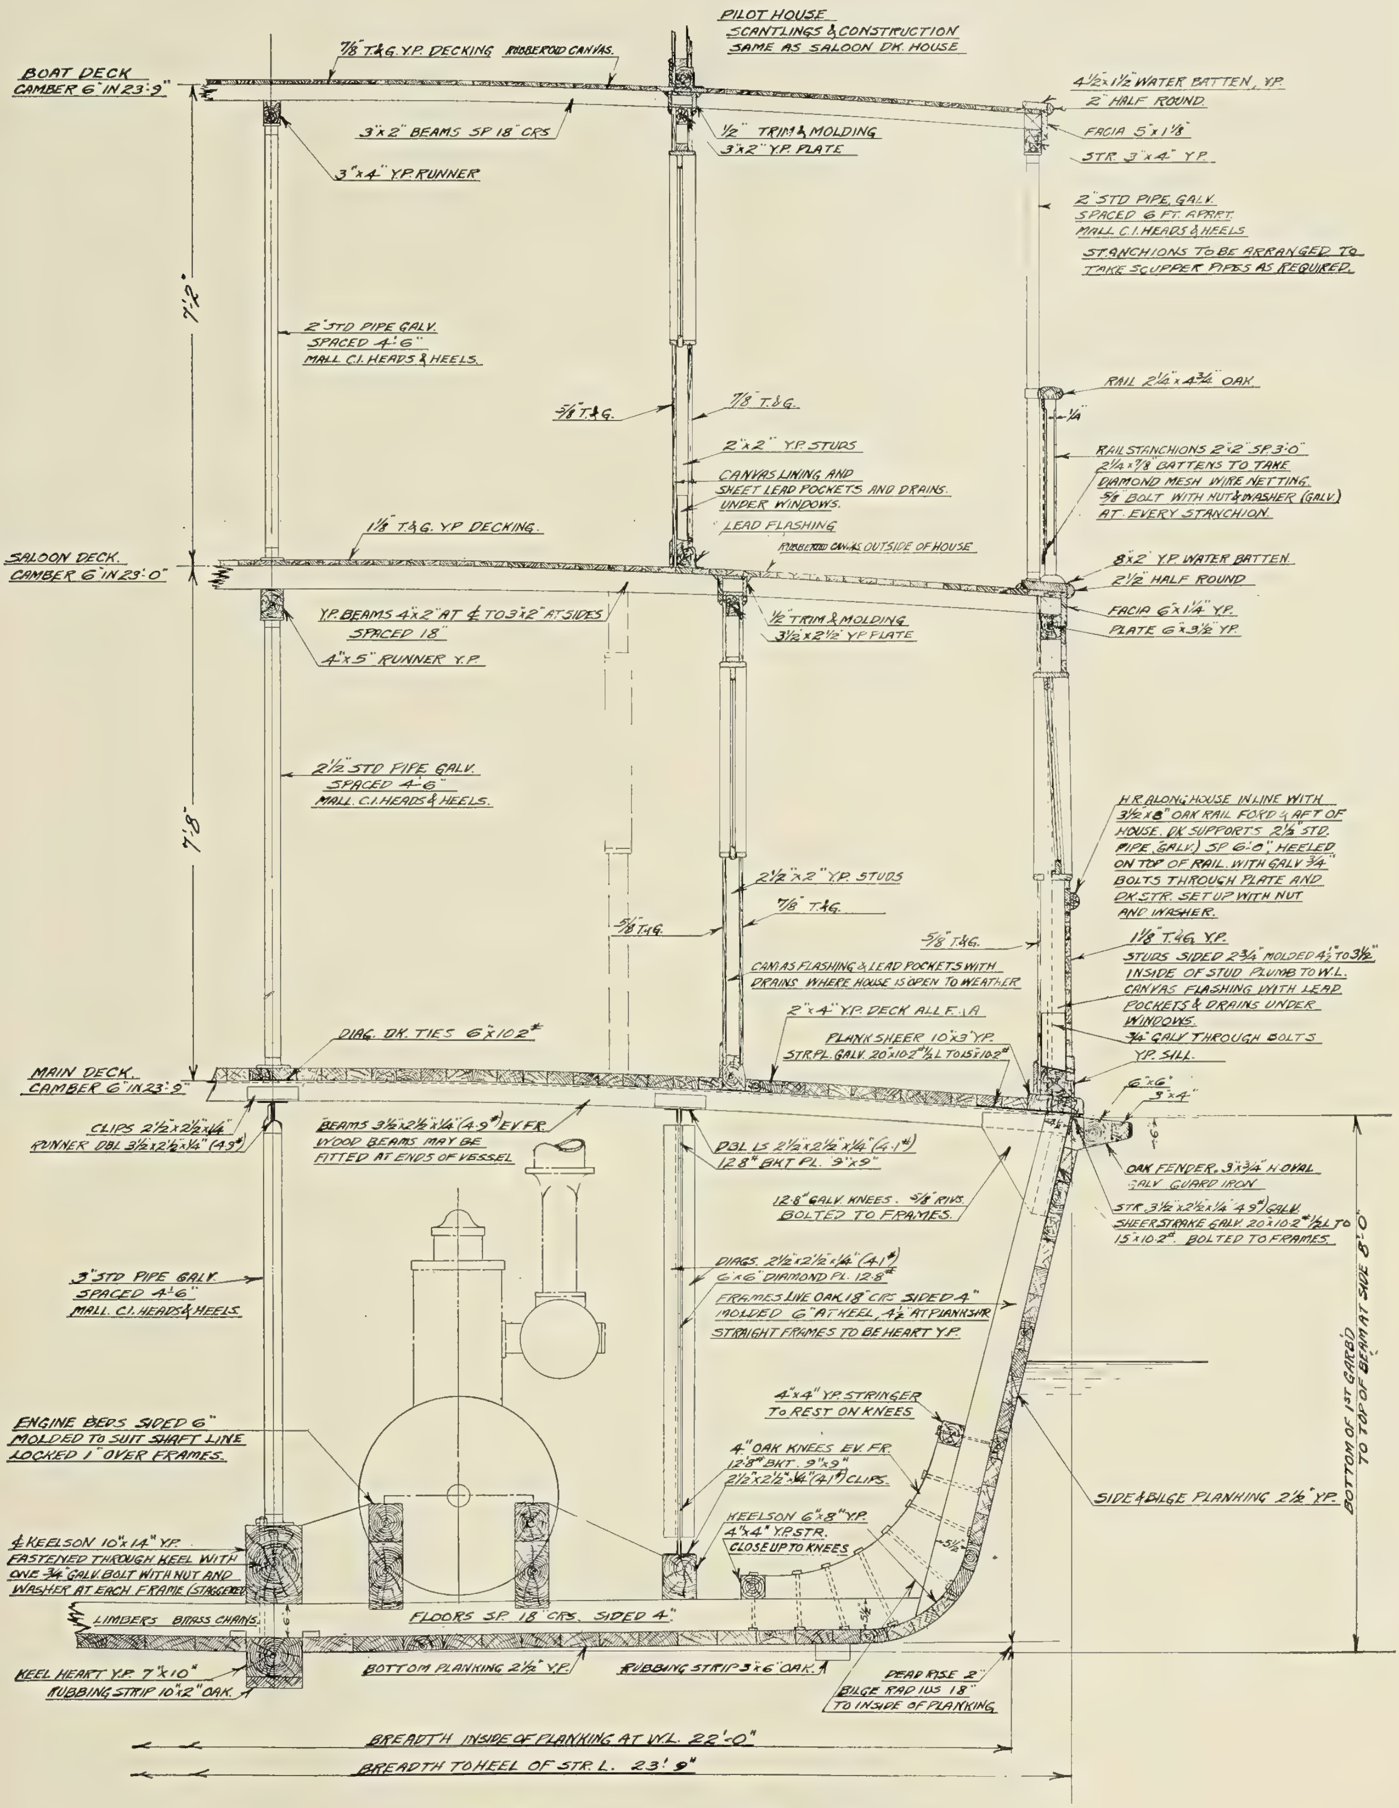
On the upper deck there is a long central deckhouse amidships, with ladies' rest room at the after end, and also a very considerable amount of promenade and lounging space, both on each side of the deckhouse and at the after end, all this space being covered by an awning deck.

The pilot house, with quarters for the captain and mate, is forward on top of the awning deck. Accommodations for the crew are below in the forecastle.

The machinery equipment consists of two 4-cylinder heavy duty oil engines built by the Kahlenberg Brothers Company, having a bore of 10 inches and a stroke of 10½ inches, which will deliver 120 brake horsepower each at 340 revolutions per minute.

This new boat will be completely equipped in every respect, the auxiliaries including an unusually efficient outfit of pumps, electric light plant and all equipment necessary for a craft of this type.

The general appearance of the new boat will be attractive, as she has pleasing lines, and with a large center stack, used for ventilation and exhaust, will present an attractive and workman-like appearance. This boat will be delivered to her new owners this month and will immediately be placed in active service.



M. S. Jeannette Scott: Midship Section

Ropes, Chains and Blocks for Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

BOTH wire and vegetable fiber ropes are made of several different materials and made up in various ways, to satisfy special requirements of strength, flexibility and wear. The relative merits of the different materials and the different ways of making them up into ropes are clearly set forth by the rope manufacturers, whose catalogs are valuable text books on the general subject. We are, however, particularly concerned with ship operating requirements, and will call attention to some of the more important considerations in this line which affect the selection of the different ropes, etc. This can be best done by dealing with them under the headings of the specific services.

Chains and blocks will be referred to under the headings where they are likely to be met with, the latter being considered particularly with reference to the ropes or chains that they have to accommodate.

Sizes given refer to ordinary merchant ship practice unless otherwise stated.

Wire Rope

When dealing with wire rope the chief considerations are strength and flexibility. The three main classifications are plow steel, cast steel and iron, the first mentioned being the strongest and the last, which is seldom required for shipboard service, being the weakest. Wire rope usually has a hemp core and in some cases each strand has a hemp core.

The purpose of this core is to increase the flexibility of the rope, to retain a lubricant which adds to the life of the rope and also to minimize internal friction from contact of the wires with each other. A mixture of a heavy bodied oil and black lead makes a good lubricant, and running ropes should be kept lubricated.

The flexibility is largely a question of the size of the individual wires used. A rope with 6 strands and 7 wires to a strand is as stiff a rope as is regularly made, and one with 6 strands and 37 wires to a strand is extra pliable. The last mentioned rope in the sizes generally met with on shipboard has wires a little too fine to withstand the abrasion of shipboard service.

Where strength and flexibility are both important factors the plow steel rope should be used rather than a larger diameter cast steel rope of equivalent strength. In some special cases bronze ropes are required. Wire ropes are often referred to as 6 x 7 rope, 6 x 19 rope, etc., the first figure being the number of strands and the second the number of wires per strand. When ordering wire rope it is well to specify that all unworked ends shall be well served.

Tables I to V inclusive give the minimum ultimate strengths that some of the wire ropes referred to later on in this article should possess. These or greater values can be readily furnished by the wire rope manufacturers. Weights can be obtained from the manufacturers' catalogs. A factor of safety of at least 5 should be used.

There is a proprietary wire rope, called "Durable," wire rope in which each strand of wires is served with a tarred hemp marline, the rope also having the customary hemp center. The serving reduces the friction between the strands and protects the wires from corrosion. The wires are not galvanized. The rope is very flexible and has found considerable favor where this factor is most important.

Fiber Rope

Fiber rope is made principally from Manila hemp, Russian, Italian and American hemp and sisal fibers. Manila, which botanically is not a hemp fiber, is much superior to the others in length, strength and lasting qualities, and is universally selected for marine purposes. Tarred hemp is

desirable for some special ropes of small diameter; other special lines are made of cotton. A yarn or thread is first made up of a number of fibers twisted together, then the strand is made up of two or more yarns twisted together in the opposite direction; the rope is formed of three or more strands twisted together in the opposite direction to the twist in the strands. A 3-strand rope is stronger than a 4-strand rope of the same size. A cable is made up of three or four of these ropes twisted together in the opposite direction to the twist in the ropes. It is not as strong as a plain laid rope of equal diameter but is more elastic and stands greater surface wear.

The strength of a rope is dependent to some extent upon the amount of twist or "lay" in it. The softer the lay, the stronger the rope, but the less the wearing qualities. The softer lays are generally desired for marine purposes. An extra strength rope obtained by a careful selection and preparation of the fibers, the use of finer fibers and a finer spinning of the threads or yarns is called bolt rope. It is a better wearing rope than the ordinary grade. Its lay is generally soft.

The general run of ropes on shipboard are of the 3-strand variety. Ropes at the Boston Navy Yard are made only in 3 strands from 3-inch circumference down, and are made in 4 strands from 3¼-inch circumference up unless specially ordered 3 strands. Four strand rope is made either with or without a center core. The latter is the marine type and has generally a softer lay than the former. Four strand rope costs somewhat more than three strand rope per pound and is from 5 to 7 percent heavier.

Table VI gives considerable data regarding the strength and other properties of Manila rope. The strengths are in accordance with Navy Department specifications and are generally somewhat lower than average strength figures for Manila rope furnished by the rope manufacturers. A factor of safety of at least 5 should be used.

Fiber rope is oiled for preservative purposes with a petroleum base oil. The finished rope should show under chemical analysis not over 12 percent of oil.

When ordering Manila rope it is well to call for a medium lay for marine purposes, to specify the circumference and strength and to require the ends of the rope to be whipped in such a manner as to prevent the unlaying of the rope when in use.

Some of the smaller ropes or "fittings" called for in ship specifications are apt to give more trouble in the determination of just what is required than the larger and more important ropes; and as they will be referred to later it will be well to define them here. They are almost always tarred and when ordered are understood to be tarred unless otherwise called for.

Houseline is a three thread hemp cord bought by the pound and running about 160 feet to the pound.

Marline is a two thread hemp cord which runs about 222 feet, 360 feet and 520 feet to the pound. The medium

weight is most serviceable about a steamship. It is bought by the pound.

Ratline is a hemp rope which ranges in size by three thread intervals from 6 threads, ¾-inch circumference, to 24 thread, 1⅝-inch circumference. It is always designated by the number of threads and comes in coils of 1,200 feet length. The 15-thread ratline, 1¼-inch circumference, is a very usual size. A coil of this rope weighs 90 pounds.

Roundline and hambpoline are three thread hemp cords which run about 92 feet to the pound. They are of opposite twist. They are bought by the pound.

Seizing is made like ratline and designated in the same manner by the number of threads, but it is ordered by the pound. The sizes are 6-thread which runs 58 feet to the pound, 9-thread which runs 40 feet to the pound, and 12-thread which runs 29 feet to the pound.

Spun yarn is made of two hemp threads running about 93 feet to the pound, and of three threads running about 77 feet to the pound. It differs from the other tarred fittings in not having so much twist in the threads or yarns. The 3-yarn variety is usually most serviceable. It is bought by the pound.

Chain

When dealing with chain the principal considerations are the nature of the chain and strength.

The principal chains met with on shipboard are stud link chain and short link or "Crane" chain. The former is used only for anchor chain cables. The type of chain called "Coil" chain is somewhat used; and it has slightly less links per fathom than the crane chain.

Crane chains are of different grades according to the quality of the iron used in them and in some cases according to the shortness of the links, the strongest chains having slightly more links per fathom than those of lower grade.

Standard proportions for stud link chains and suitable strengths for both the stud link and the short link chains of different sizes can be obtained from the classification society rules and tables, and these are values which chain makers have to live up to.

Table VII gives data regarding the short link chain made by Bradlee & Company. This is selected for reference because the proof test and breaking strain of the "crane" chain are for most sizes identical with the proof test and break test required for short link chains by the American Bureau of Shipping. Strength figures of other manufacturers are in some cases higher than those in the table. It will be noted that a factor of safety of 3 is recommended. In other cases this factor is recommended for the "Special Crane" chain and a factor of safety of 4 for the lowest grade of "Crane" chain and for "Coil" chain. The factor to use in any case depends upon the nature of the work. With chain used in a purchase for lifting or moving loads it is desirable to add about ⅓ to the estimated pull on the line for friction.

It is especially desirable that chains around drums or sheaves have short links in order to lie close without risk of bending.

Anchor chain cables of 1-inch or more diameter of iron are usually of stud link chain and where a vessel is classed stud link chains as small as 11/16-inch are called for.

Anchor chain cables 1⅜-inch and over in diameter may be made of cast steel as well as of wrought and welded links, the former having received classification society approval in 1918, and also having stood up well in service.

Blocks

Blocks for marine use should be of substantial construction. The general practice is to use steel blocks with wire ropes and wood blocks with fiber ropes. The latter should be of the heavy, wide mortise, double cross bolted type, with shell of well seasoned ash reinforced with inside iron straps. On small blocks for yachts, etc., the shell is sometimes of lignum vitæ. Wide mortise steel blocks can be obtained for fiber ropes and all gin blocks are of iron or steel. The bushings are selected according to the service; desirable bushings for the different services will be found noted under the respective headings. Blocks can be obtained with a great variety of shackles, hooks, jaws, eyes, eyebolts, etc., to meet the particular requirements of the service. Some general requirements for shipboard use are:

All blocks to have metal sheaves.

All steel blocks and the ironwork of all wood blocks to be galvanized.

Sheaves in all blocks to be suited to the rope or chain. With rope the diameter of the groove at the tread should be 1/16 inch greater than the diameter of the rope.

Upset shackles to have heart thimbles.

Steel blocks are usually specified according to the size of the sheave and wood blocks according to the size of the shell.

With wire ropes it is important that the sheave diameters be of ample size so as not to cause rapid wear of the ropes. The wire rope manufacturers recommend that the sheave diameter be at least 20 times the diameter of the rope and in their catalogs call for considerably larger sizes to suit the differing degrees of flexibility of the ropes. The Navy Department specifications call for 15 diameters or more. In ordinary merchant ship work, rope economy is often sacrificed to convenience, but good practice with wire rope calls for the use of sheaves about 20 times the diameter of the rope.

Wood blocks generally run about 14 inches for 4½-inch circumference fiber rope, 12 inches for 4-inch rope, 10 inches for 3½-inch and 3-inch rope, 8 inches for 2¾-inch and 2½-inch rope, 7 inches for 2¼-inch and 2-inch rope, 6 inches for 1½-inch rope, 4 inches for 1⅛-inch rope, etc.

Sheaves or drums for chains are preferably 30 or more times the diameter of the chain, but this generally cannot be provided for on shipboard.

Where block shackles have to connect to bands, etc., it is important to provide that the shackles and pins are of the proper size.

In services where a purchase is desirable the blocks and ropes have to be considered together and a proper selection made of both. For instance, with the lead off of the upper block and the weight on the lower block, a combination of two double blocks with a becket on the upper one will cause a pull on the rope of one-fourth of the weight, whereas, with a triple upper block and a double lower block with a becket on the latter the pull on the rope will be only one-fifth of the weight. There would of course be an additional pull due to friction in each case.

Accommodation Ladder

Accommodation ladder falls are preferably of fiber rope, for easy handling. With the usual run of cargo ship ladders, 2¾-inch Manila with a 10-inch double block below and a 10-inch triple block above makes a good combination. On some small ladders 8-inch double and single blocks are used with the same size rope. The upper block has a loose hook and no becket; the lower block has a loose front hook and a becket. Graphite bronze bushings are desirable.

Anchor Light

Manila rope 1⅛-inch circumference will usually answer for this, with 4-inch single wood block with regular shackle and graphite bronze bushing.

Awnings

Wire rope for the support of awnings is preferably ⅜-inch diameter, galvanized cast steel, 6 by 19 construction, with ultimate strength as given in Table V.

Dredge Chains

Dredge chains for various operating services are subject to hard usage and should be of the highest grade of short link chain.

(*To be continued*)

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Propeller Problem

Q. (1171).—I have been following with interest the excellent articles of Admiral Dyson, especially his latest exposition of the propeller problem. In this connection I have come across a difficulty in the solution of the problem of the double ended ferry boat discussed in MARINE ENGINEERING AND SHIPPING AGE, I believe, during the early part of 1921. I cannot give the date as it was cut off in careless clipping.

After having derived the basic I.H.P. and E.H.P. for the 210-foot ferry, the author proceeds as follows:

$v = 12.73$	12.73
$v/V = 0.67$ (12.73/19)	0.789 (12.73/16.14)
Log $A_v = 3.82$	.....
$A_v = 6500$	4093
Log $A_v = 3.15$	.....
$A_v = 1380$	2043
$N_v = 147.9$	147.9
$(1-s) = 0.9135$	0.9135
$s = 0.0865$	0.0865
$\text{I.H.P.}_d = s \dfrac{\text{I.H.P.}A_v}{S A_v} = 1020$	787
$K = 1.36$	$M_r = 1.05$
$\text{I.H.P.}_p = \text{I.H.P.}_d/K = 750$	$787/1.05 = 750$
$10^z = \text{I.H.P.}/\text{I.H.P.}_d = 5.105$	5.105
$Z = 0.73342$	
e.h.p./E.H.P. = for Z, 0.209	

Now, in Dyson's new method, Z_s for $v/V = 0.67$ is 0.4, not 0.67 (which latter is obtained from $Z_s = (A_v - A_v)$. How can the two be reconciled? Again, for $10^z = 5.105$. the log, which gives $Z_p = .708$ and for this e.h.p./E.H.P. is not 0.209. Is this correct?

Lastly, what is M_R? Dyson makes no mention of it.

In an article by Mr. Bates, second trial, Ap. 1921, p. 336, he begins by selecting (e.h.p./E.H.P.)g. Dyson uses e.h.p./E.H.P. Is this correct?

In Dyson's Fig. 2, for values H/B greater than standard, how are the direction lines obtained? Doubling the H/B value shows a corresponding point to be at BC=2/3 original BC. Is this purely accidental?

A. (1171).—The original curves of A_v and A_v were plotted on actual speeds from the trials of a few ships. As Admiral Dyson's investigations proceeded he found that, when the performance of other vessels were applied, inconsistencies in revolutions appeared which could not be accounted for and he saw that some other method of obtaining them was necessary. So instead of using the actual speeds as a basis, a speed ratio was decided upon from actual performances of many vessels and up to the present time has proven to give consistent results. This curve bears no relation to the original curves.

For the Z_p value of 0.708 I can see no reason why the correct reading of e.h.p./E.H.P. should not be 0.209.

M_r was a corrective factor for indicated horsepower and revolutions where the values of e.h.p./E.H.P. and $^v/V$ obtained from the analysis of the estimated or actual performance of a propeller plotted on the cavitation chart showed cavitation existed. This M_r factor is no longer used in these calculations.

By starting with gross load fraction values of (e.h.p./-E.H.P.)g much work is often eliminated, especially when it becomes necessary to design fairly close to the cavitation region, as we are certain at the start that the load fraction e.h.p./E.H.P. of the actual propeller when the value of K is applied will not put the propeller into cavitation.

The fact that doubling the value of H/B decreases the original BC by 2/3 was accidental, also interesting.

Derivation of Resistance Constant

Q. (1174).—On page 641 of MARINE ENGINEERING AND SHIPPING AGE, October, 1922, in the article, "Resistance of Ships to Propulsion," by A. J. C. Robertson, is given the following formula:

$$\text{Resistance constant (C)} = \frac{1.3115\ R}{\Delta^{2/3}\, v^2}$$

Can you indicate to me how the constant 1.3115 in above formula is obtained?

A. (1174).—The resistance constant $(C) = 427.1 \dfrac{\text{E.H.P.}}{V^3 \Delta^{2/3}}$

$$(1)\quad (C) = \frac{427.1\ \text{E.H.P.}}{V} \times \frac{1}{V^2 \Delta^{2/3}}$$

$$(2)\quad \text{E.H.P.} = \frac{R \times V \times 101.33}{33{,}000}$$

Substituting the value of E.H.P. given by equation (2) in equation (1)

$$(C) = \frac{R\ V}{V} \times \frac{101.33}{33{,}000} \times 427.1 \times \frac{1}{V^2 \Delta^{2/3}}$$

$$(C) = \frac{1.3115\ R}{V^2 \Delta^{2/3}}$$

Motorships vs. Steamships

Q. (1175).—I am much interested in the Diesel engine for marine purposes and have been for years. Do you not think our shipbuilders and owners are failing to serve their own best interests by clinging to the steam engine in its various forms? Should they not even in vessels of fair speed and size turn to the Diesel?

A. (1175).—This is too large a subject to handle satisfactorily in this department. The following suggestions are believed worthy of note but are by no means considered to cover the subject.

The Diesel engine is at present essential to and is used successfully in the submarines of all navies. It is used successfully in powers up to 2,000 or 2,500 per unit in many modern cargo vessels. During the past several years a number of large private yachts have been furnished with this type of machinery. Passenger liners 500 feet in length with speeds of 13½ knots and Diesel engines of 6,000 horsepower are under construction. The writer understands that all the large shipbuilding companies of this country are now prepared to furnish and install this type of machinery. This fact of itself testifies to a recognition of its possibilities.

So much for what has been and what is being done. The Diesel engine, while very economical of fuel, while operating with a smaller force of men than other types of machinery and while eliminating the steam boiler entirely except for heating is of great first cost, requires the attention of specially trained engineers, is relatively very heavy and at present is limited in power to units of say 4,000 to 5,000 horsepower. Perhaps we know too little as yet to make comment on the size of the repair bill for this type as compared with that of others.

The selection of the machinery installation for a ship is a matter of careful consideration resolving itself finally into the old question of the return on the investment.

Your attention is invited to the following articles published in Marine Engineering and Shipping Age:

"Cargo Motorship versus Steamship," by Chas. E. Lucke, September and October numbers, 1920.

"Internal Combustion Engines Applied to Propulsion," by John F. Metten and J. C. Shaw, July, 1921.

"Diesel Electric Propulsion," by J. B. Bassett, August, 1921.

"Diesel versus Steam Drive," by J. E. P. Grant, May, 1922.

NEW BOOKS

Burning Liquid Fuel

Reviewed by J. A. Kelley*

Burning Liquid Fuel. By William N. Best. Size, 6 by 9 inches. Pages, 336. Illustrations, 316. New York, 1922. U. P. C. Book Company, Inc.

"Burning Liquid Fuel" purports to be "a practical treatise on the perfect combustion of oils and tars, giving analysis, calorific values and heating temperatures of various gravities with information on the design and proper installation of equipment for all classes of service."

Briefly, the author opens with reminiscences dating back to his earliest experiences in the West in 1887, followed by profuse tables of oil production, taken mainly from Geological Survey reports. In the chapter on atomization, the author states that all burners may be grouped in three distinct classes, *viz.:* "mechanical, internal mixing and external mixing." He then describes the merits of the type of burner manufactured by himself—which is, of course, in the external mixing class, whereby oil at about twelve pounds pressure is fed into a sheet blast of steam at boiler pressure or compressed air. Incidentally, a photograph is included entitled *mechanical burner.* The author claims that "with low pressure or volume air you are limited to the use of light oils, whereas with compressed air or steam as atomizer, you can use any gravity of crude oil, fuel oil, kerosene or tar, which will flow through a one-half inch pipe." The writer checked back to verify that this book came off the press in 1922, yet all marine men know full well that the Shipping Board standard bunker oil is 14-16 Baumé and that all marine installations, except in a few minor instances, are of the mechanical type of atomization. Adaptions of the *Best system* are described, which permit the use of pulverized coal, thereby opening up the opportunity for the economical use of a fuel which otherwise is wasted or inefficiently used. Tables dealing with the quantity of steam lost in atomizing per boiler horsepower hour are conspicuous by their absence.

The chapter on *oil systems* includes many diagrams of typical piping installations for land use with attendant suggestions and directions, together with photographs of fittings used by the author. A description of a centrifugal air compressor, operated by a condensing turbine, is also included, which is recommended for marine use, with the view to eliminating the necessity for additional boiler make-up, which the steam blast requires.

The remainder of the book is devoted to particular installations and usages, including locomotive equipment, stationary and marine boilers, low pressure boilers and hot air furnaces, commercial gas industry, sugar industry, steel foundry, heat treating, malleable iron, grey iron and brass foundry and forge shop practice, boiler manufacturers' furnace, copper industry, enameling, chemical industry, ceramic, lime and cement equipment, dryers, ore roasters, bread and cracker ovens, chocolate industry, oil and tar still, incinerator and glass industry equipment.

Under *Marine Boilers* all that can be found is a rather illegible diagram, on page 94, attempting to show the *Best burner* adapted to a Scotch marine furnace, with no descriptive matter amplifying. The chapters on oil burning in the various lines of industry, enumerated above, are quite replete with diagrams (there are 316 sketches in the book) and the salient points in the several installations are covered, as well as the general claim for the superiority of oil over coal in each case.

Tucked away under the heading of *Modern Forge Shop Practice,* the author digresses into quite an eulogy on oil, the superb fuel, in which he points out that the power of a nation depends on its conservation of oil. He says, "I hope that the heat from this fuel will be tempered by love so that it may be a nation which will use its power for good, governing with righteousness its people and bringing a reign of peace to the world. . . . Unfortunately the World War has created a demand for this fuel in marine service and our government has equipped many boilers on vessels without making any preparations for a change back from oil to coal." The author then becomes quite alarmed over the shortage of fuel oil for the industries, particularly forge shops, and "sees no reason why the Navy should use oil, if this fuel is in such demand by the manufacturers of our country. . . ." (page 218).

After resuming the subject of oil burning in modern forge shop practice, the author again digresses, saying (page 225), "I am well aware that oil in marine service is attractive because of the saving effected in labor, there being no discharging of ashes, as well as the time saved in charging the fuel oil on the vessel as against the time required for loading of coal; and also the advantage of being able to increase the speed of the vessel, the cleanliness and improved sanitary conditions, as well as the fact that this fuel elevates the mind of the fireman, as his duty does not require mere brawn but brains for the scientific burning of oil, and gives him the feeling that though he is housed up in a hot boiler room (much cooler because of the use of oil as fuel), he is 'a man for a' that'." He does admit that two tugs on oil can do the work of three on coal, but seems to disregard the vital economic phase for the merchant marine. "Yet," he continues, "we must consider the use and the many advantages of this fuel for the manufacturers whose products must furnish at least part of the cargo for these vessels, else they will be operated at a loss."

After continuing with his descriptions of oil burning installation, in forge shop practice, the author, on page 227, again harps back to his theme. He says, "the men in marine service will get a new vision also, and, that is—in forging industry—oil is even more attractive than in marine boiler equipment on ocean going vessels because a great deal more labor can be saved in a forge shop than in marine service, to say nothing of the increased output and superior quality of the product from the forge shop. In times of peace oil should be used only upon as few naval boats as possible. It should be used on some vessels, however, owing to the fact that the men should be trained in the art of operating oil burners. It would be well to have the boilers of the vessels interchangeable so that they can readily be changed from coal to oil, and from oil back to coal, for in case of war oil should be used, if possible, on naval vessels. I know there are a large number of merchant vessels now being equipped with oil in order to save labor and avoid strikes. I believe that will only be used temporarily, but I am equally confident that the nation which conserves its ore and gives its manufacturers all the oil they require will be the manufacturing nation of the future."

The reader is almost led to infer that the burners coming

* Naval Architect, Morse Dry Dock and Repair Company, Brooklyn, N. Y.

under the class of "external mixing" have not received much of an ovation on the sea.

The final chapter, on *Combustion Engineering,* points out the dearth of men able to burn fuel successfully and scientifically—of *engineers in caloric,* and also discourses on vocational successes, closing with a reference to the Lincoln Memorial University of Tennessee, which he claims to be the only institution teaching scientific oil burning.

Although the author himself seems to be quite impressed with his literary contribution to the field of oil burning, the book cannot be recommended to marine engineers as having any particular value, nor of containing data for their use not already plentifully supplied in the advertising literature issued by makers of the various types of burners. The text itself is confined to a particular type of burner. Coming from the pen of Dr. Best, who is universally acclaimed as a pioneer and authority on oil burning, the book is somewhat disappointing.

It is to be regretted that the author has treated the marine field with such little notice, for the number of vessels fitted for oil burning and the large number now being fitted or contemplated shows that the marine field is worth consideration by such an authority as the author. In short, the book is an elaborate catalog advertising the author's wares.

LETTER TO THE EDITOR

Explosions on Oil Tankers

On account of the extreme hazard encountered by repair yards in the overhauling and repairs to oil tankers and vessels carrying fuel oil, also on account of the frequent resulting explosions, it becomes necessary to take the utmost precautions to prevent these accidents.

While a frequent examination for gases acts as a precautionary measure against the accumulation of the same, it very often occurs that pipe joints may not be absolutely tight, thereby allowing the escape of gases into the tanks and, in conjunction with the heavy atmospheres of summer time and saturated atmosphere of early spring and fall, the gases accumulate and lie in the extreme corners of these tanks. In other words, the tank may be entirely free from gas on first examination, while final examination may show traces of the same. To minimize the risk involved to the lowest possible point, a change in design of tank tops and bulkheads seems to be the proper point at which to start these precautions.

This change would not require to be radical, but a portable plate about 4 feet by 6 feet, with stud bolts, located near the ends of each tank would help to solve the problem. These plates could be located on the inner bottom tanks, on the sides of summer tanks, top of expansion trunk and on fore and after peak tank bulkheads, or wherever fuel oil, or cargo oil, is carried. The manhole to these tanks can be located in these portable plates and, whenever repairs are required in the tanks, an insistent demand be made that these plates be removed to allow free escape of gases and entrance of fresh air; also to allow an easy exit from same, and for an easier prosecution of the work.

If this is insisted upon by the United States Steamboat Inspection Service and by the classification societies and the underwriters, fatalities and damage will become greatly reduced; this will also result in a lower cost of repairs.

Philadelphia, Pa. H. Fisher, Superintendent, Kensington Shipyard Department, The William Cramp & Sons Ship & Engine Building Company.

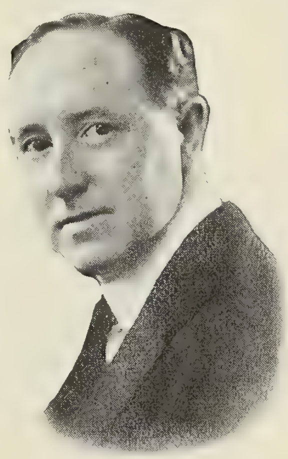
PERSONAL MENTION

William J. Du Bois, recently with the United States Shipping Board at 45 Broadway, New York, has retired from the shipping industry, and will take up his residence at Newport, N. H. Mr. Du Bois has been connected in the marine field for twenty years, having held a chief engineer's license for nearly forty years. His activities and experience have brought him in contact with the operation of marine engines of all kinds in all parts of the world. For twelve years he was superintendent of the American Mail Steamship Company, leaving the employ of this company when its ships were transferred to the Pacific coast. His experience also includes the superintending of construction of the New York city ferryboat *Mayor Gaynor.* During the last five years he has been in the service of the United States Shipping Board, and his retirement will be considered a personal as well as a business loss to the New York division of the Shipping Board.

Wm. J. Du Bois

Captain Eugene E. O'Donnell, of Boston, Mass., has been elected American director of the International Shipping Service Federation.

H. Jasper Cox, recently appointed principal surveyor for Lloyd's Register of Shipping in Japan, began his career in shipbuilding in 1900 when he became an apprentice at the works of Swan, Hunter and Wigham Richardson, Wallsend-on-Tyne. During his apprenticeship he pursued his professional studies at Armstrong College of the University of Durham, and in 1907 at the Royal Naval College, Greenwich. In 1909 he was appointed a surveyor on the chief ship surveyor's staff of Lloyd's Register of Shipping, London, where for six years he was principally engaged in examining survey reports and construction plans of all types of vessels. In 1915 he came to the United States to perform similar work, and in 1916, when the American committee of Lloyd's Register was formed, he was appointed assistant to the chief surveyor for the United States and Canada. In 1920 he became acting principal surveyor on the chief ship surveyor's staff and proceeded to Japan to open an office for the approval of plans for vessels building and to be built in Japan and other countries of the Orient. While in Japan he helped establish the Japanese Committee of Lloyd's Register with Mr. K. Uchida, member of the House of



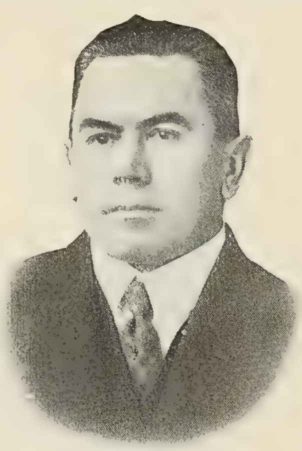
H. Jasper Cox

Peers, as chairman. Early in the present year he returned to this country to resume duties as assistant to the chief surveyor. On December 12 he will sever connections here and within a few months take up his new duties as principal surveyor for Japan.

W. J. Love, vice-president and general manager of the Emergency Fleet Corporation, has been placed in full charge of the North Atlantic District of the Emergency Fleet Corporation and the United States Shipping Board with headquarters in New York city. He will continue as vice-president of the Emergency Fleet Corporation, and will have in charge the management of the New York organization and supervision on behalf of the Board of the operation of all its passenger lines. Mr. Love came to the Fleet Corporation in July, 1921, recognized as one of the ablest traffic and shipping men in America. For sixteen months he has served as vice-president and trustee of the Emergency Fleet Corporation, being associated with President Smull in charge of the operation of the Government's fleet. With the combined experience of private practice and that gained in the operation of Government ships, Mr. Love will be particularly qualified to take charge of the Shipping Board's broad interests in New York.

W. J. Love

Louis R. Ford, who has just been appointed manager of the Diesel engineering department of the Morse Dry Dock and Repair Company, Brooklyn, N. Y., served in the United States Navy for 17 years. During this time he was assigned to special engineering duty by the Secretary of the Navy, in connection with Diesel engine work. During the war he was in charge of the maintenance of submarines operating along the Atlantic coast. In 1919 he resigned from the Navy as a lieutenant commander and accepted a position with the Worthington Pump and Machinery Corporation as consulting Diesel engineer. He resigned from this connection with the Worthington Corporation on November 30 to assume his new duties with the Morse company.



Louis R. Ford

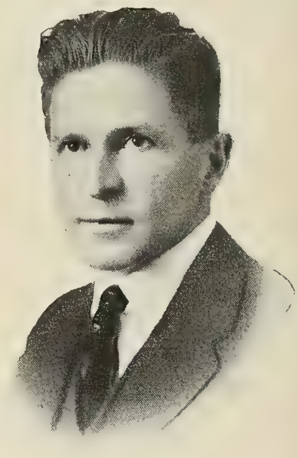
W. B. Keene, formerly assistant to W. J. Love, has been elected a trustee of the Emergency Fleet Corporation, and will assume management of the traffic department in the Washington office.

Carlos de Zafra, president of Seabury and De Zafra, Inc., consulting naval architects and marine engineers, has been appointed to the engineering faculty of the New York University in connection with the new Russell Sage Research Laboratory of Mechanical Engineering. He will conduct lectures on power plant engineering and carry out tests on various installations of steam, oil and electric machinery. Professor de Zafra will continue his service as a consulting marine engineer with headquarters at New York University.

H. F. Alexander was re-elected president of the Pacific Alaska Navigation Company, holding company for the Pacific Steamship Company (the Admiral Line), at the annual directors' meeting.

C. N. Wonacott, vice-president and secretary of the Atlantic, Gulf and West Indies Steamship Company has resigned to become vice-president of the Multomah Lumber and Box Company, Portland, Ore.

H. W. Parsons, formerly with the marine department of the General Electric Company, has recently joined the marine department of the Power Specialty Company to handle the well known Foster boilers and superheaters. A native of California, Mr. Parsons was first associated with the Bay Counties Power Company. He later joined the marine department of the Southern Pacific Company of California, leaving that company to act as sales engineer for a number of marine contractors. In 1911, he joined the turbine department of the General Electric Company and was transferred to the marine department of that company at the outbreak of the war. In December, 1921, Mr. Parsons left that company to take charge of the New York office of John R. Proctor, Inc., constructing engineers, leaving there in October, 1922, to become associated with the Power Specialty Company.



H. W. Parsons

John M. Born has been appointed agent for the intercoastal service of the United American Lines at Atlanta, Ga., with offices at 1108 Candler Building.

George G. Browne, formerly surveyor for the American Bureau of Shipping at Havre, France, has been appointed exclusive surveyor for that organization at Panama.

Lynn W. Nones, formerly with the Griscom-Russell Company, has been appointed eastern manager of the marine department of the Diamond Power Specialty Corporation with offices at 90 West street, replacing F. W. Leahy, who lately resigned.

E. B. Sadtler, formerly with the Oscar Daniel Shipbuilding Company, is now affiliated with the Peabody Engineering Corporation, New York.

William T. Donnelly, consulting engineer, New York, delivered an illustrated lecture on "Safety First on Our Harbor Waters" before the Staten Island Chamber of Commerce at the Curtis Annex Auditorium, Port Richmond, New York, on Thursday evening, November 2.

H. J. Finch, assistant to James Sinclair, Far East and Africa traffic manager for the Shipping Board, has resigned to join A. H. Bull and Company, as manager of its West African service.

Gilbert W. Yarus, until recently chief fuel inspector at the New York office of the United States Shipping Board, is now in charge of the bunkering department of the Seiler Coal Company, Inc., of 90 West street, New York.

How you can make Four Boilers do the work of Five

A BATTERY of four Todd Elesco Superheater Boilers replaces five boilers in which superheater equipment is not included.

That is not a guess. It's a fact. We figure it on that basis when an owner gets tired of wasting one-fifth of all his coal and orders Superheaters installed while his ship's in port.

Get these figures. The saving in coal runs better than 10% for quadruple expansion engines, 12% for triple expansion engines, and 18% in compound engines using Todd Elesco Superheater equipment, as against the cylinder condensation losses which go with the old-fashioned use of saturated steam.

There are close to 3000 vessels equipped with *Todd Elesco Type Superheaters*—so our figures are based on a tonnage of over 3½ million indicated horse power.

With Todd Elesco Superheaters on oil burners you get such figures as .913 lbs. of oil per I.H.P. hour (S.S. Eastern Ocean); .921 lbs. of oil I.H.P. hour (Eastern Cloud); 11 knots per hour on 220 lbs. of oil in 24 hours (S.S. Robin Adair), and so on.

Todd Shipyards are in business to increase the efficiency of American shipping. This is one of our several economy gaining steam specialties.

If you want to know how to get more space for revenue cargoes, how to cut your coal bill about 20%, how to make four boilers do the work of five—ask us to send you full data on Todd Elesco Superheaters.

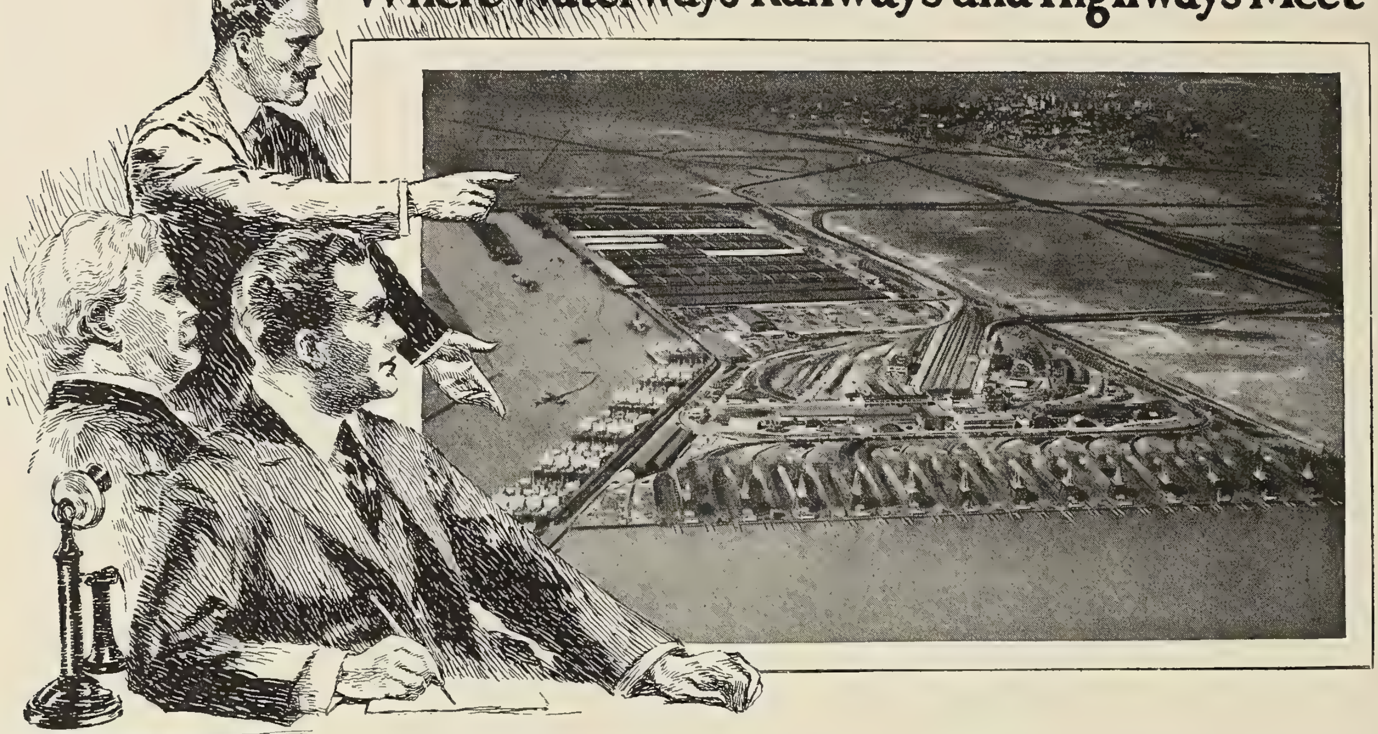
Where Waterways-Railways and Highways Meet



PORT NEWARK

THE MIRACLE OF MODERN TIMES

Most shipping and factory centers have grown up without planning. We see evidence of this during normal times in port congestion, in shortage of storage and loading and unloading facilities.

We also see factories located on expensive land, or too far from primary markets, or inconvenient for employees to reach and often lacking proper railway connections.

Port Newark is a correctly and scientifically planned shipping terminal and industrial center. On the New Jersey mainland, a part of the Port of New York, it is nearer lower New York Bay than Manhattan Island is. Seven trunk line railroads connect with its belt line railroad.

At Port Newark rail-to-ocean steamship delivery becomes an actuality on the Atlantic seaboard. There is no lighterage necessary. The channel is 31 feet deep; and an inland ship canal 7,000 feet long and 650 feet wide will have a ship turning basin at its end.

Three railroad classification yards are nearby. Three heavy duty roadways connect with the Lincoln Highway and other main trucking thoroughfares. Newark is ten minutes away, and New York is reached in twenty minutes by truck.

Ten million people live within fifty miles of Port Newark, the biggest market in the world. Labor supply is plentiful and diversified, the labor population is over 200,000. Newark and its suburbs offer comfortable and economical housing for all classes of labor.

Land values are lower at Port Newark. The space you need, the shipping facilities you require are at Port Newark. What will your needs be within the next five years? Write

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Bethlehem Corporation Awarded Contract for Construction of Hudson River Line Steamer

THE contract for the construction of a new paddle wheel steel steamer for the Hudson River Day Line has been awarded the Bethlehem Shipbuilding Corporation, on a bid of $742,140. The new vessel, which was designed by J. W. Millard & Brother, naval architects, 17 State Street, New York City, will have an over all length of 338 feet, extreme breadth 76 feet and depth molded to main deck at side of guard 13 feet 8 inches. She will be propelled by a diagonally inclined triple expansion steam engine, steam being supplied by two single and two double-ended Scotch boilers. The steamer is to be furnished complete with the White Fuel Oil Engineering Corporation mechanical fuel oil burning system.

Although first bids were received on October 20, the date of delivery of the new boat was postponed until April 1, 1924, and a second set of prices requested. The tenders submitted were as follows:

	First Bid	*Second Bid*
Federal Shipbuilding Co.	$695,000	$695,000
Bethlehem Shipbuilding Co.	742,140	742,140
Sun Shipbuilding Co.	815,254	815,254
New York S. B. Co.	980,000	959,000
Bath Iron Works	1,030,000	980,000

Contract for Construction of Red "D" Line Ship Awarded to New York Shipbuilding Corp.

THE New York Shipbuilding Corporation has been awarded the contract for the construction of a new passenger and freight ship for the Red "D" Line, bids for which were taken several weeks ago. The vessel will be driven by turbine engines and was designed by Theodore E. Ferris, naval architect and marine engineer, of 30 Church Street, New York City.

The tenders offered contained about 44 proposals, which included prices for the ships equipped with McIntosh & Seymour engines, Busch-Sulzer engines, Burmeister & Wain engines and the Sun-Doxford engines. The types of turbine engines figured on included the De Laval, Parsons, Curtis and Westinghouse makes. In addition to the 44 bids, proposals were made by each shipbuilder to construct one and two ships on the Isherwood system, stating the saving in weight and price.

The ship is to have an overall length of 320 feet and will be of the two-deck shelter deck type driven by twin screws and will be equipped to carry about 50 first class and 25 second class passengers. The vessel will be built to American Bureau Classification. Bids submitted were as follows:

Company	Reciprocating Engines — Price each for — One ship	Two ships	De Laval Turbines — Price each for — One ship	Two ships	McIntosh & Seymour Diesel Engines — Price each for — One ship	Two ships
Federal Shipbuilding Co.	$753,700	$723,700	$789,000	$765,000	$879,000	$849,000
New York Shipbuilding Corp.	740,000	740,000	798,000	798,000	852,500	852,500
Bethlehem Shipbuilding Corp.	781,000	756,000	831,000	811,000	910,000	890,000

Federal Shipbuilding Company Gets Contract for Construction of Two 262-Foot Diesel Propelled Ships

IT is reported from authentic sources that the Federal Shipbuilding Company, Kearny, N. J., has been awarded the contract for the construction of two Diesel propelled ships for the United States Steel Products Company. The boats will be of the full Welland Canal size and will probably be operated through the canal in the open season and in Southern waters in the winter time. It is understood the total cost will be close to $1,000,000.

The vessels will each be 262 feet over all, length 250 feet on the keel, 43 feet beam and 20 feet deep. They will be equipped with Diesel oil burning engines and electric hoists.

Sun Company to Convert Covedale to Diesel Drive

THE Sun Shipbuilding Company has been awarded the contract for reconditioning the Munson Line steamer *Covedale.* The steam engine in the ship is to be replaced with one 900 brake horsepower, 6-cylinder, 4-cycle McIntosh & Seymour Diesel engine and the auxiliaries are to be electrically driven instead of by steam. A small auxiliary boiler will supply steam for heating purposes, the contract to be completed in about 75 days. It is understood the total cost will be close to $130,000.

Fletcher Yard Lowest Bidder for Resolute

WITH a price of $99,973, the W. A. Fletcher Company, Hoboken, N. J., submitted the lowest bid for the work of reconditioning the steamship *Resolute,* of the United American Line. The tenders were opened November 21, with the following results:

Fletcher	$99,973
Robins	146,200
Tietjen & Lang	149,780
Morse	172,560
Newport News	182,000

Bids Asked for Ten Steel Barges for Rock Island

UNITED States Engineer Office, Rock Island, Ill., will receive bids until 10 A. M., December 11, for the construction and delivery of 10 steel barges. The vessels are to have a length of 100 feet, beam molded 30 feet and depth molded 6 feet. The deck fittings will include four 36-inch cleats, four 7-inch double bitts and four 30-inch open chocks, all of cast steel. The bids are to be delivered afloat at a port on the Mississippi River between Dubuque and Keokuk, Iowa.

Alderton Dry Docks Gives Lowest Price for Liberty Job

THE Alderton Dry Docks Company tendered the lowest bid for the work of repairs to the steamship *Liberty.* Prices were received by the Shipping Board, 45 Broadway, New York, on November 22, as follows:

Alderton	$12,290
N. Y. Harbor	13,653
Staten Island	14,633
Atlantic Basin	17,200
Robins	18,565

Tide Water Oil Co. Plans Three New Steel Barges

PLANS and specifications have been issued by the Tide Water Oil Company, 11 Broadway, New York City, for the construction of one, two and three steel barges, of the scow type, each having a capacity of 300,000 gallons of bulk oil.

The proposed boats are to have a length, inside fenders, of 162 feet; breadth, inside fenders, 36 feet; depth molded, amidships, 10 feet; draft, molded, 9 feet 6 inches. Each boat will have a continuous steel, watertight bulkhead fitted on the center line for the full length of the oil tanks and there will be five oil tight transverse bulkheads. The hatches are to be fitted in groups of four, one forward and one aft. A deck house, about 16 feet by 12 feet by 7 feet three inches, will be located aft, built of 7½ pound plating. It will be equipped with four galvanized pipe berths, shipmate range, etc., the living quarters to be provided with all necessary fittings.

Equipment

A three-inch hand force pump of approved make will be fitted in each compartment, with 2-inch bilge suctions.

Cast iron fittings to be supplied include the following: four 9-inch towing bitts; six open chocks; six heavy mooring cleats; two Providence hand power capstans.

There are also to be furnished one 650-pound stockless anchor; 45 fathoms of ¾-inch chain cable; 45 fathoms of ¾-inch wire hawser; one 14-foot wooden workboat.

Cargo Pump

There is to be one pump, 14 by 10½ by 18 inch horizontal duplex, of approved make, capable of discharging 750 barrels per hour when operating at a piston speed of not over 85 feet per minute with a working steam pressure of 100 pounds per square inch.

Heater Coils

The coils in each compartment are to consist of a coil or grid about 50 feet long, and a length of pipe in every frame space for full width of compartment.

Engineer Office at Pittsburgh to Have New Dredge

UNITED States Engineer Office, Pittsburgh, Pa., will receive sealed proposals until 12 o'clock noon (Eastern time), December 1, for constructing and delivering one steel dipper dredge hull afloat at Pittsburgh. The hull will have a molded length of 100 feet, molded beam 34 feet, depth forward above base 6 feet 8 inches, depth aft above base 6 feet 8 inches.

After delivery of the hull, the contracting officer will furnish and install all machinery, boiler and stack; dipper, complete with "A" frame; boom and back stays; spuds; all sheaves; planking for top of deckhouse; operator's house and skylight over boiler. The vessel will be built to the rules of the American Bureau of Shipping and the longitudinal system of framing will be used.

One approved syphon, with 2-inch discharge, will be installed in each compartment, the contractor to furnish and install all necessary piping, valves, fittings, etc.

Two Diesel-Electric Drive Ships Proposed for Great Lakes; Lombard Governor Co. Gets Engine Contract

THE Minnesota Atlantic Transit Company, of Duluth, Minn., is contemplating the construction of two Diesel electric drive vessels, according to reports from the Great Lakes district. Henry Penton, of Cleveland, Ohio, is the naval architect preparing plans and specifications.

It is understood that the Lombard Governor Company, of Ashland, Mass., manufacturers of Lombard oil engines (Diesel system), has been awarded the contract for four 6-cylinder 375 horsepower Diesel engines and two 2-cylinder 60 horsepower auxiliary engines for the proposed vessels. Information as to who will build the ships was not obtainable at this time.

French Company Adopts Oil Fuel for Its Ships

THE Compagnie des Messageries Maritimes owns a certain number of oil-burning ships and has decided to make further use of oil as a vessel-fuel, according to information received by the Department of Commerce, Washington, D. C., from the American Consul at Marseilles, France. The ships of this company include the *Lieutenant de Missiessy* and the *Lieutenant de La Tour*,—the former built in England and the latter in America; and a steamboat, the *Angkor*, refitted at La Ciotat in 1921. Another vessel, the *Amazone*, will be refitted in a short time. Two large boats under construction, *Leconte de Lisle* at La Ciotat and the *Aramis* at the shipyard of La Gironde, will be oil-burners; as will all ships built for this company in the future. However, the equipment of the vessels will be so arranged that the substitution of coal may be easily effected in case the price of oil becomes prohibitive.

The Compagnie des Messageries gives the following advantages derived by vessels from the use of oil as fuel: (1) reduction of crews, (2) regularity in power and thus in speed, (3) reduction in expense of boiler maintenance. It is stated that experiments prove that when oil is substituted for coal as fuel on vessels, the boilers give much longer service.

Four Contracts Awarded to the Johnson Works

THE Johnson Iron Works, of New Orleans, La., was awarded the contract for installing Falk gears and overhauling the machinery of the steamship *West Wauna*, new bids for which were recently taken by the United States Shipping Board. The prices submitted were as follows:

Johnson Iron Works	$24,400
Galveston Dry Docks	25,907
Todd D. D. & S. B. Co.	25,969
Jahncke Dry Docks	26,942
Alabama D. D. & S. B. Co.	29,000

The Johnson Works was also the successful bidder for the contract to furnish and install a new shaft on the stern wheel river tug of the Mississippi-Warrior service, at an approximate price of $4,000.

Other awards made to the same company include the work of installing new plates in the turbine and minor repairs to the turbine auxiliaries on the steamship *West Sequoia;* and the making of repairs on the steamship *El Demar,* including the shortening of masts and minor repairs to machinery and piping.

Bids Asked for Building of Three Steel Deck Barges

UNITED STATES Engineer Office, Pittsburgh, will receive sealed proposals until 12 o'clock noon, Eastern Time, November 25, for furnishing and delivering three steel deck barges. The boats are to have a molded length of 120 feet, molded beam 32 feet, molded depth 7 feet, depth of hull at center 7 feet 4 inches.

Each barge is to be symmetrical about the centerline, wall sided, flat bottomed, with rounded bilge, without shear, and deck pitched 4 inches between the centerline and gunwale. There are to be two transverse watertight collision bulkheads, one longitudinal watertight centerline bulkhead and one transverse watertight bulkhead. The deck fittings will include six cast steel watertight hatches, four cast steel towing bitts; four cast steel kevels, not less than 46 inches in length and suitable for a 2-inch rope.

United States Ship Houston Is to Be Converted to Oil

THE Hanlon Shipbuilding and Dry Dock Company, of Oakland, Cal., was low bidder for reconditioning the *U. S. S. Houston*, with a tender of $20,468. The work called for converting the vessel from coal to oil-burning, in addition to other changes, to be completed in 28 days. The following companies submitted bids, which were:

Bethlehem Shipbuilding Co.	$26,638
Los Angeles Shipbuilding Co.	27,359
Main Iron Works	30,088
United Engineering Co.	32,986
General Engineering Co.	36,014
Moore Shipbuilding Co.	40,125

Bids in for S. S. Swiftstar Repairs; Newport News Low

THE Newport News Shipbuilding & Dry Dock Company has been awarded the work of reconditioning the Steamship *Swiftstar*, of the C. D. Mallory Company, tenders for which were opened on November 8.

The bids were as follows:

Newport News	$171,500	60 days
Robins	198,000	75 days
New York Harbor	251,600	80 days
Morse	295,000	80 days
Crane	381,920	90 days

The City of Los Angeles left on her first trip from Los Angeles to Honolulu, September 11th. Upwards of three hundred members of the Los Angeles Chamber of Commerce with their wives and families were on board. The service is to be fortnightly, sailing from Los Angeles and from Honolulu every second Saturday from September 23rd until further notice.

Seven Steel Barges, Two Boilers, Two Turbines, Pumps and Equipment Wanted By War Department, Memphis

THE War Department, Office of the Mississippi River Commission, for the First and Second District, of Memphis, Tenn. (Flood Control, Mississippi River), has issued specifications for the construction of six and seven steel barges and the furnishing of turbines, pumps, feed-water heater, boiler feed pumps, electric light plant and boilers, sealed proposals to be received at the office of the Commission, Customhouse, Memphis, Tenn., until 11 A. M., December 2.

Barges

Prices are to be submitted for six and seven steel barges, each to have a molded length of 120 feet, beam 30 feet, depth of hold at center 7 feet 4 inches, beam 30 feet, depth of hold at side 7 feet. There are to be four continuous transverse watertight bulkheads, and each barge is to be equipped with ten hatches and two towing bitts at each end.

Boilers

The work contemplated by the boiler specifications consists of furnishing two horizontal internally fired boilers of the Clyde or dry-back type without steam dome, fitted with Morison corrugated furnace, or equal, grate bars, firebrick-lined combustion chambers, dry pipes and compound separators. Each boiler shall be of 125 horsepower and have not less than 1,250 square feet of heating surface, the furnace not less than 48 inches in diameter, grate surface not less than 28 square feet and flues of not less than 3½ inches in diameter and each provided with a hydrokineter. They are to be designed for a working pressure of 200 pounds per square inch.

It is proposed to erect the boilers side by side on suitable saddles, the saddles to be furnished by the contractor and constructed to conform to the crown of the deck.

Turbines

Two steam turbines, each direct-connected to a 4-stage centrifugal pump, complete with flexible couplings, shall be furnished and installed, and each turbine and pump shall be mounted on a cast iron base. The steam turbine shall be designed to run condensing in conjunction with one waterworks type surface condenser and air pump of sufficient capacity to handle all the exhaust steam from both turbines. Each steam turbine shall be designed to operate on 150 pounds gage pressure at the throttle, with 26-inch vacuum at the exhaust nozzle, at a speed of not more than 2,000 revolutions per minute.

Pumps

The pumps shall be the horizontal shaft, 4-stage centrifugal type, adapted to the speed of the turbine, and shall be designed to deliver 750 gallons of water per minute, each, against a pressure shown by suitable gage attached to the discharge nozzle of 225 pounds per square inch. The suction lift will be approximately 10 feet.

Condenser

The condenser, designed to be installed in the suction line to the pump, will have not less than 600 square feet of tube surface.

Twelve Contracts for Repairs Go to N. Y. H. Yard

THE contract for repairs to the steamship *Nile* was awarded to the New York Harbor Dry Dock Company, following the opening of bids, November 10, by the Shipping Board, at 45 Broadway. Prices submitted:

New York Harbor	$4,533
Alderton	5,279
Clinton	5,347
Crane	6,439

Tenders were opened by the Board on the same day for repairs to the steamship *Sarcoxie*, which was also awarded the New York Harbor Dry Dock Company on their bid of $1,135.

The steamers *Westport* of the Shipping Board, *Cosmos* of the Ellerman Lines, *Sapanta* of the Standard Transportation Company, oil barge *No.* 5 of the Tidewater Oil Company, *West Gotomska* of the Shipping Board, *Somerset* of the Standard Oil of New Jersey, *Argen* of the Standard Oil of New York, *Castle Lodge* and *Westerner* of the Shipping Board and a sub chaser of Sloan Danenhauer, are also recent contracts awarded the New York Harbor Dry Dock Company and not the Staten Island Shipbuilding Company, as previously reported.

Steamer, Barge and Terminal Construction Program in Hands of Philadelphia Engineering Firm

Chapman and Fisher Company, Inc., Preparing Plans and Specifications for River Passenger Steamer, Ferryboats and Barges in Addition to Three Piers

THE construction of a new passenger steamer, two ferryboats, several tank barges and rebuilding of other tank barges for Chesapeake Bay service, in addition to the construction of two 700-foot covered piers and a coaling pier, are among the latest propositions on the boards of Chapman & Fisher Company, Inc., consulting engineers and naval architects, 524 Walnut Street, Philadelphia, Pa.

The firm recently opened bids for rebuilding the passenger steamer *New Jersey*, for service on the Delaware River, for the account of the Burlington Island Amusement Company. The prices submitted for the work were $119,500; $177,000; $210,000; $273,000.

New Construction

The new vessel proposed is to be a first-class passenger excursion steamer having a length of 240 feet, 35 feet beam, 60 feet over guards and 12 feet deep. She is to be driven by compound inclined engines. The speed is to be about 14 knots.

The dimensions for the two ferryboats have not yet been determined and probably will not be available for about 60 days. The boats will be for service to Delaware River ports.

With regard to the construction and rebuilding of tank barges, which will be for Chesapeake Bay service, details were not available at this time although plans and specifications are expected to be completed in December.

Pier Work

The Chapman & Fisher Company have also taken over a proposition to engineer and construct a water terminal along the Atlantic Seaboard, probably a South New Jersey port. The plan is to build two 700-foot covered piers for the storage of grain, package freight and bulk oil and also to construct a coaling pier. Considerable dredging and wharf building will be involved in the terminal project. The matter is expected to be in sufficient detail to secure bids on this work early in February and a meeting of the stockholders, controlling the operation, to determine the extent of expenditures, is arranged for late in November.

198 Steel Vessels of 255,431 Gross Tons Under Contract Oct. 1, Increase Shown Over September

ON October 1, 1922, American shipyards were building or under contract to build for private shipowners 198 steel vessels of 255,431 gross tons compared with 131 steel vessels of 249,999 gross tons on September 1, 1922.

These figures do not include Government ships or ships building or contracted for by the United States Shipping Board.

Following is a summary of reports of shipyards to the Bureau of Navigation, Department of Commerce, showing the number and gross tonnage of steel vessels under construction or contract for private owners on October 1, 1922:

Companies.	Number.	Gross tonnage.
American Bridge Co., Ambridge, Pa	79	36,082
The American Shipbuilding Co., Cleveland, Ohio	7	53,000
Bethlehem Shipbuilding Corp., Ltd.:		
Baltimore Dry Docks Plant, Locust Point, Baltimore, Md	2	2,020
Harlan Plant, Wilmington, Del	5	2,736
Sparrows Point Plant, Sparrows Point, Md	3	17,550
Union Plant, San Francisco, Calif	2	......
Charles Ward Engineering Works, Charleston, W. Va	5	1,400
Consolidated Shipbuilding Corp., Morris Heights, N. Y	1	300
Dravo Contracting Co., Pittsburgh, Pa	20	6,690
Dubuque Boat and Boiler Works, Dubuque, Iowa	2	275
Federal Shipbuilding Co., Newark, N. J	5	18,500
Great Lakes Engineering Works, River Rouge, Mich	3	16,820
Howard Shipyards Co., Jeffersonville, Ind	2	995
James Rees & Sons Co., Pittsburgh, Pa	1	175
Johnson Iron Works, Dry Dock and Shipbuilding Co., New Orleans, La	2	750
Kyle & Purdy, Inc., City Island, N. Y	3	810
Los Angeles Shipbuilding and Dry Dock Corp., Los Angeles, Calif	2	3,500
Marietta Manufacturing Co., Point Pleasant, W. Va	11	4,050
Nashville Bridge Co., Nashville, Tenn	3	1,000
Newport News Shipbuilding and Dry Dock Co., Newport News, Va	3	13,000
New York Shipbuilding Corp., Camden, N. J	10	30,690
The Pusey & Jones Co., Wilmington, Del	4	8,300
Riter-Conley Co., Pittsburgh, Pa	10	9,000
Staten Island Shipbuilding Co., Port Richmond, N. Y	5	2,738
Sun Shipbuilding Co., Chester, Pa	3	13.650
Toledo Shipbuilding Co., Toledo, Ohio	1	8,200
Wm. Cramp & Sons Ship and Engine Building Co., Philadelphia, Pa	3	2,100
Union Construction Co., Oakland, Calif	1	1,100
Total	198	255,431

Contract Award

The contract for the construction of three steel dump scows, bids for which were opened November 7, by the United States Engineer Office, Buffalo, N. Y., has been awarded the Penn Bridge Company, Beaver Falls, Pa. The company's price was $92,120.

Bunkering Ship Contracted for at New Orleans, La.

IN order to take care of their steadily increasing business, the Consolidated Fuel Company, Inc., of New Orleans, La., has contracted with the Johnson Iron Works, of that city, for the construction of a steel collier hull, 110 feet by 35 feet by 6 feet 6 inches, for delivery early in 1923. The boilers and conveyor machinery are to be furnished and installed by the owner. The contract price for the hull and tower was $25,300 and the total investment will probably be about $50,000. The latest type machinery will be installed in the vessel and she will be able to deliver coal at the rate of 200 tons per hour.

The Consolidated Fuel Company, Inc., was organized in February of this year with Mr. H. E. McCormack, President, R. P. Hyams and H. C. Whiteman, Vice-Presidents, and Charles Harrington, General Manager. Mr. I. B. Whiteman, for many years engaged in the bunkering of ships at New Orleans has recently become associated with the company in the capacity of marine superintendent.

Proposals Asked for Construction of Nine Barges

SEALED proposals will be received at the office of the Mississippi River Commission, Third District, P. O. Box 404, Vicksburg, Miss., until 11 A. M., December 14, for furnishing nine steel barges. Each boat will have a length molded of 120 feet, beam molded 30 feet, depth of hold at center 7 feet 4 inches, depth of hold at side 7 feet.

Each barge shall be of steel construction throughout, flat-bottomed, with rounded knuckles, wall sided, symmetrical about the center line, with a rake 15 feet long, a sheer 12 inches high at each end, and a crown of beam of 4 inches. Transverse framing lines shall be spaced uniformly 30 inches. There shall be four continuous, transverse, watertight bulkheads, one non-watertight longitudinal plate bulkhead over the center line, and two symmetrically disposed longitudinal stiffening trusses.

Bethlehem Buys Simpson's Patent Dry Dock Company

THE Bethlehem Shipbuilding Corporation has purchased the plant of the Simpson's Patent Dry Dock Company, whose main office is located at 23 Ames Building, Boston, Mass. The yard is on Marginal street, East Boston. It was established in 1856.

Three graving docks have been maintained, one 465 feet long, one 250 feet long and one 150 feet long. The company's officers were, Charles F. Crowell, president; Ezra H. Baker, vice-president, and Arthur M. Baker, general manager.

It is announced that the drydock company's yard will be continued in operation as a ship repair plant under the direction of the Fore River branch of the Bethlehem Corporation.

Bids Taken for Reconditioning of Steamer Valdura

PROPOSALS for the repair of the steamship *Valdura,* which sustained damage as a result of going aground in the Hawaiian Islands, were opened at noon on November 22, at the office of Macfarlane, Garmey & Company, 32 Broadway, New York City. Robins Dry Dock & Repair Company, with a price of $65,650 and 30 days' time, submitted the lowest figure. The bids, which have been submitted to the owners for decision, were as follows:

		Days
Robins	$65,650	30
Tietjen & Lang	69,840	35
Bethlehem	71,700	33
Morse	82,000	35
Newport News	107,400	50
New York Harbor	117,421	60

Steamer Manitowoc Repair Work Goes to Alderton Shipyard

THE contract for repairs to the steamer *Manitowoc,* bids for which were received by the Foreign Transport & Mercantile Corporation, New York, has been awarded the Alderton Dry Docks Company, at a price of $3,797. The tenders were:

Alderton	$3,797
Morse	3,869
Staten Island	4,156
Tietjen & Lang	4,970
Robins	5,125
Fletcher	6,800

Transport Logan Goes to Bethlehem West Coast Yard

THE Bethlehem Shipbuilding Company, of San Francisco, Cal., was low bidder for reconditioning the United States army transport *Logan.* The work called for extensive alterations on the vessel's passenger accommodations and life-saving equipment. Tenders were as follows:

Bethlehem Shipbuilding Co.	$16,989
Moore Shipbuilding Co.	24,527
De Young Company	25,985
Hanlon S. B. & D. D. Co.	28,750

Midland Barge Co. is Lowest Bidder for Derrick Hull

THE Midland Barge Company, of Midland, Pa., with a price of $13,800, was low bidder for the construction of one steel derrick boat hull at the opening of bids by the United States Engineer Office, Pittsburgh, Pa., on November 20. The boat is to have a molded length of 80 feet, molded beam 34 feet and molded depth 5 feet. The bids were as follows:

Midland Barge Co.	$13,800
Independent Bridge Co.	14,300
Pennsylvania Bridge Co.	14,600
Dravo Contracting Co.	16,450
Charles Ward Engineering Works.	16,500
American Bridge Co.	17,000

Shipping Board Graduates Its First Classes in Study of Fuel Oil Burning and Development

Class No. 1, Shipping Board Fuel Oil School.
Top row, left to right: Messrs. Henning, Healey, Phelan, Clavin, Smith, Shoe.
Second row: Messrs. Klein, Jefferson, Stevens, Norton, Grace, Cunningham.
Front row: Messrs. Hobbs, Sullivan, Peterson, Brierly, Brierly.

THE first class in the Shipping Board's Fuel Oil School, which has been established at the Philadelphia Navy Yard under the general direction of the Navy and Fuel Conservation Committee of the Shipping Board, has completed its course of instruction. All the members of this class were exceedingly enthusiastic over the prospects of success for the school. The Fuel Conservation Committee hopes to further the science of oil burning in the American merchant marine and in that way to contribute to the greater efficiency of our vessels.

As an indication of the interest inspired by this course, the assistant port engineer of one of the large steamship companies states that information given out at the school was immediately put to practical use on one of his steamers.

"I took the opportunity on October 28," he said, "of giving the chief and the first and second assistant engineers a full two hours' instruction covering several important points that were brought out in the course, taking these men inside of one of the boiler furnaces and explaining in detail important points with regard to burner adjustments, refractories, etc.

"You may recall on the steamship *Satartia* (fitted with three B. & W. boilers) that we had the crew rebuild six side walls complete on her last voyage to India, placing the necessary material on board prior to sailing. This work, as you know, was very well done and made a considerable saving in repair bills."

A second class of instruction began on November 7 and was made up of thirteen engineers including representatives from the Munson Line, Moore & McCormack, United States Lines, J. H. Winchester & Company, Kerr Steamship Company and the Mallory Transport Company. The third class began November 20.

Susquehanna Job Goes to Atlantic Basin Iron Works

THE steamship *Susquehanna* was awarded the Atlantic Basin Iron Works for repairs as a result of bids received by the Shipping Board, 45 Broadway, New York, on November 20. The prices submitted were:

Atlantic Basin	$15,290
Morse	18,680
Tietjen & Lang	21,119
New York Harbor	23,840

Shipping Board Offers Four Ships at Public Sale

THE Shipping Board is offering for sale four ships built by the Los Angeles Shipbuilding and Dry Dock Company, namely, the *West Greylock, West Faralon, West Chopeka* and *West Prospect,* of 10,000 deadweight tons each and ranked among the finest of the fleet. The board is holding them for more than $30 a ton each, according to Sidney Henry, director of sales.

BUSINESS NOTES

The committee on docks, piers and wharves, of the National Fire Protection Association, will hold a meeting on Tuesday, December 13, at 9:30 A. M., in the room of the National Board of Fire Underwriters, 67 William Street, New York City. It is expected that this meeting will be the most important meeting of the committee up to this time. Charles H. Fischer is chairman of the committee.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Reconditioning, Norfolk, Va.—The Lake Gallien went to Norfolk to be reconditioned.

Repairs to Steamer, Oakland, Cal.—Steamer La Placencia was placed on ways at Moore Shipyard, Oakland, for repairs.

Admiral Liner Drydocked, West Coast.—Admiral liner Spokane went to Todd Harbor Island plant to be cleaned and painted.

Steamer Repaired, Superior, Wis.—Steamer C. S. Robinson went to Superior to be repaired. Twenty-six plates were replaced.

Vessel Overhauled, San Francisco, Cal.—Pacific Mail Steamship President Cleveland went to Bethlehem plant for overhauling.

Contract Awarded, Hoboken, N. J.—W. & A. Fletcher Company awarded contract for repairs to steamship Fegundo. Price $7,000.

Miscellaneous Repairs, Chester, Pa.—Union Oil Company's tanker Puento went to Sun Shipyards to be drydocked for miscellaneous repairs.

Damaged Steamer Drydocked, Galveston, Tex.—Steamship Saccarappa went to Galveston for repairs to damages sustained in foreign waters.

Shipbuilding, Whitehaven, Md.—The Whitehaven Shipbuilding Company is rebuilding three large schooners and is overhauling seven others.

Cleaning and Painting, San Francisco, Cal.—The Rose Mahony went on Bethlehem Shipbuilding Company's drydock for cleaning and painting.

Steamship Reconditioned, Philadelphia, Pa.—Steamship Tippah, of the Inland Steamship Company, went to a local yard for reconditioning.

Steamer Drydocked, Providence, R. I.—New Bedford steamer Ucatena was hauled out on the East Providence drydock for scraping and painting bottom.

Plates Repaired, Seattle, Wash.—Freighter Ketchikan went to the Todd plant to have plates repaired. Several punctured plates will be replaced.

Tanker Repairs, Chester, Pa.—Tanker Chester Sun, owned by the Sun Oil Company, was drydocked at the Sun shipyard at Chester for repairs.

Contract Awarded, Hoboken, N. J.—W. & A. Fletcher Company was awarded the contract of reconditioning the steamer Eastern Trader. Price $81,000.

Bow Replacement, San Francisco, Cal.—Steamer Sudbury went to Bethlehem Shipbuilding Company, San Francisco, to have several of its bow plates replaced.

Tanker Inspected, San Francisco, Cal.—Shipping Board tanker Hamer went on drydock for inspection prior to being taken over by the General Petroleum Company.

General Repairs to Steamer, New Orleans, La.—New York and Porto Rican Steamship Company's steamship Carib went to Johnson Iron Works for general repairs.

Repairs, San Francisco, Cal.—Mexican steamer Colima and motorship Cycol went to the Barnes & Tibbitts' yards to undergo general overhauling and minor repairs.

Lengthening of Vessel, New Orleans, La.—Ferryboat Ruth went to Johnson Iron Works to be lengthened fifteen feet and to have her guards widened three feet.

Two Steamers to be Reconditioned.—After their next round voyages, the Resolute and Reliance, of the United American Lines, will be withdrawn from service and drydocked to be conditioned for their winter cruises.

Overhauling of Steamer, New Orleans, La.—Johnson Iron Works awarded contract to install Falk gears and overhaul machinery of steamship West Wauna. Price $24,400.

West Coast Activities.—The Bethlehem Shipbuilding Corporation, San Francisco, was awarded the following: Harbor Tug James N. Gilette, steamer Ebian and steamer Mahoe.

Annual Inspection, Seattle, Wash.—Steamship Starr, operating in mail service from Seward, Alaska, westward, will go to Seattle for annual repairs, inspection and overhauling.

Repairs to Barge, Staten Island.—The New York Harbor Dry Dock Company was awarded the contract for repairs to the East Jersey Railroad Company's barge No. 26. Price $6,013.

Oil Barge Launched, New Orleans, La.—Johnson Iron Works recently launched a 5,100-barrel capacity oil barge to be used by the Southern Paper Mills. It is 144 feet long and is of steel.

Ferryboat Launched, San Francisco, Cal.—Steel ferry steamer Shasta was launched at the Union plant of the Bethlehem Shipbuilding Corporation for the account of James Rolph & Company.

New Shaft on Tug, New Orleans, La.—Johnson Iron Works awarded contract to furnish and install new shaft on stern wheel river tug of Mississippi Warrior Service. Approximate price, $4,000.

Repairs to Steamers, Staten Island, N. Y.—New York Harbor Dry Dock Company, Staten Island, was awarded repairs to steamships Nile and Sarcoxie. Prices $4,553 and $1,135, respectively.

Liner to Undergo Reconditioning.—At the conclusion of its next round voyage the George Washington, of the United States Lines, will be withdrawn from service for a month to be reconditioned.

Tug Drydocked, Savannah, Ga.—Tug W. B. Keene, Savannah-New York Transportation Company, went on ways of the Wilkinson Marine Railway & Drydock Company to have new propeller and shaft fitted.

Contract Awarded, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the contract to replate the bow of the freighter Walter Luckenbach, damaged in a collision. Price $20,934 and 16 days.

Isonomia Contract, Baltimore, Md.—The latest addition to the Foster Fleet, is the Pacific Freighters Company steamship Isonomia, recently fitted with Foster Waste Heat Type Superheaters, at Baltimore, Md.

Contract Awarded, Hoboken, N. J.—The contract for the conversion of 17 tugs and 5 lighters, of the New York Central Railroad Company, was awarded to Tietjen & Lang plant of the Todd Shipyards Corporation. Approximate expenditure, $250,000.

Conversion to Oil Burner, Newport News, Va.—The Newport News Iron Works, Inc., of Newport News, Va., is completing the contract awarded to them by the E. K. Wood Company, of San Francisco, of converting the Lake Bridge from coal to oil burner.

Possible Reconditioning.—It is reported in marine circles that the steamship Plainfield, of 4,112 deadweight tons, has been sold by the Shipping Board to the Baltimore and Carolina Steamship Company and that there is a strong possibility of the new owners reconditioning the ship.

Westinghouse Reduction Gears, Pittsburgh, Pa.—The Compagnie Generale Transatlantique (French Line), Paris, has ordered from the Westinghouse Electric & Manufacturing Company, East Pittsburgh, six sets of double reduction, floating frame type gears of 6,000 horsepower each.

Award of Contract, Savannah, Ga.—Wilkinson Marine Railway and Drydock Company was awarded the contract of work on Martin's Industry Light Vessel No. 1. Specification called for exterior work on the hull, including scraping and painting below the water line, and refinishing the hull.

Extensive Reconditioning, San Pedro, Cal.—The Lake type Shipping Board freighter Cowiche, purchased on the East Coast several months ago by the California and Oregon Lumber Company, went to the plant of the Los Angeles Shipbuilding and Dry Dock Corporation to undergo extensive reconditioning.

Contracts Awarded, New Orleans, La.—The following were awarded to the Jahncke Dry Dock Company: Tanker Anomia, to be refitted and have stern post straightened; steamship West Jaffrey, minor repairs; steamer Nacata, to undergo extensive repairs; Shipping Board steamship Lafcomo, repairs.

Bethlehem Yard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Company was awarded the following repair jobs, including cleaning and painting: Steamers Lurline, Carlos and C. A. Smith, barkentine Echo, schooner Alumna, steam schooner Katherine, motorship Oronite and barge Erskine M. Phelps.

Bunkering Ship, New Orleans, La.—Consolidated Fuel Company, New Orleans, awarded contract to Johnson Iron Works for construction of steel collier hull, 110 feet by 35 feet by 6 feet 6 inches, for delivery in 1923; boilers and conveyer machinery to be furnished by owner. Contract price for hull and tower, $25,300.

Contract Awarded, Camden, N. J.—The contract for the construction of a new passenger and freight ship for the Red "D" Line was awarded to the New York Shipbuilding Corporation; ship to have overall length of 320 feet, driven by twin screws and equipped to carry about 50 first class and 25 second class passengers.

Extensive Repairs, Bremerton, Wash.—The steamship Empress of Australia was awarded to Todd Dry Docks Company, Seattle, for extensive reconditioning. The company deemed it advisable to do the work at the United States navy yard's graving dock instead of attempting to lift the big ship in the Seattle floating dock.

Miscellaneous Contracts, New Orleans, La.—Following contracts awarded Johnson Iron Works: work of installing new plates in turbine and minor repairs to turbine auxiliaries on steamship West Sequoia; and making of repairs on steamship El Demar, including shortening of masts and minor repairs to machinery and piping.

Construction of Two Ships, Kearny, N. J.—Federal Shipbuilding Company was awarded contract for construction of two Diesel propelled ships for United States Steel Products Company. Boats will be 262 feet over all, length 250 feet keel, 43 feet beam and 20 feet deep, ships to be equipped with Diesel oil engines and electric hoists.

Steamers Change Ownership, Norfolk, Va.—A trade has been made between the Buxton Line and the Norfolk and Mobjack Bay Steamboat Company by which the former acquired the steamer Ocracoke, formerly owned by the Old Dominion Steamship Company, and the latter, the steamship Sieur De Monts, purchased recently by the Buxton Line from the army.

Contracts for Oil Burners, New York.—Standard Transportation Company, New York, installed in one of their tugs a complete installation of Peabody-Fisher wide range oil burners. The Western Union Cable Company placed a contract for the removal of oil burning system in the cable steamer Lord Kelvin and installation of Peabody-Fisher wide range burners.

Vessel Repairs, Staten Island, N. Y.—The following vessels were awarded to the New York Harbor Dry Dock Company for repairs: Westport, of the Shipping Board; Cosmos, Ellerman Lines; subchaser Sloan Damenhauer; Sapanta, Standard

Transportation Company; oil barge No. 5, Tidewater Oil Company; West Gotomska, Shipping Board; Somerset, Standard Oil of New Jersey; Argen, Standard Oil of New York; Castle Lodge and Westerner, Shipping Board.

Steel Electric Cable Ship, New York.—Bids will be received until December 4 by J. W. Millard & Brother, naval architects, 17 State Street, New York City, for construction and outfitting and delivery of a steel twin screw, Diesel electric, cable laying vessel for the Western Union Telegraph Company; length from fore side of stern to after side of stern post on 16-foot waterline, 211 feet; breadth molded 34 feet; depth molded to upper deck, 18 feet 6 inches.

New Passenger and Freight Steamer, Seattle, Wash.—The Todd Shipyards Corporation was awarded a contract to build a twin screw combination passenger and freight steamer for the Alaska Steamship Company. The vessel will have a length of 350 feet between perpendiculars, 47 feet 6 inches beam, draft of 20 feet, speed about 16 knots, cargo capacity 2,500 tons, accommodations for 235 passengers and will burn oil fuel with Todd mechanical burners.

GOVERNMENT WORK

Dredging, Norfolk, Va.—U. S. Engineer plans dredging in Appomatox River.

Dredging, New York, N. Y.—U. S. Engineer, 2nd District, plans dredging in Raritan River.

Steel Hull, Huntington, W. Va.—U. S. Engineer plans to purchase steel hull for quarter-boat.

Maneuver Boat, Huntington, West Virginia.—U. S. Engineer plans to purchase maneuver boat for Dam 30.

Dredging, Puget Sound.—Specification 4708.—Bureau of Yards & Docks, Navy Department, Washington, D. C., rejected bids for dredging Puget Sound.

Piers, Pearl Harbor.—Specification 4687.—Bureau of Yards and Docks, Navy Department, Washington, D. C., will soon receive bids for two 335-foot reinforced- concrete piers, 18 feet wide, including dredging and filling.

SHIPYARDS AND DRY DOCKS

Dry Dock Plant Purchased, Boston, Mass.—The Bethlehem Shipbuilding Corporation has purchased the plant of the Simpson's Patent Dry Dock Company, whose main office is located at 23 Ames Building, Boston, Mass. The yard is on Marginal street, East Boston. It was established in 1856.

Three graving docks have been maintained, one 465 feet long, one 250 feet long and one 150 feet long. The company's officers were: Charles F. Crowell, president; Ezra H. Baker, vice-president, and Arthur M. Baker, general manager. The yard will be operated as a ship repair plant under the direction of the Fore River branch of the Bethlehem Corporation.

Firms Consolidate, Boston, Mass.—The engine and ship repair business and good will of the Bertelsen & Petersen Company, of East Boston, has been purchased by the Atlantic Works of East Boston. Jens Bertelsen is to become vice-president of the Atlantic Works, and Paul Bertelsen will be works manager, both becoming stockholders and directors by the new arrangement. Such machinery as can be used to advantage in the Atlantic Works will be removed and the balance of the Bertelsen & Petersen plant will be closed out. The Atlantic Works will put in a large floating drydock of some 10,000 tons capacity. The company already has three marine railways.

PORT IMPROVEMENTS

Pier, Montreal, Que.—Sterling Construction Company, Montreal, Canada, was awarded a contract by Montreal Harbor Commissioners for 300-foot extension to Jacques Cartier Pier. Price $150,000.

Wharf, Montreal, Que.—Harbor Commissioners awarded a contract to Barrett-McQueen, Ltd., 373 Canada Cement Building, to build 500 foot concrete extension to Imperial Oil Wharf, Longue Pointe. Price $200,000.

Contract Placed, Norfolk, Va.—Another unit was added to the Norfolk municipal terminal development project when the City Council, by a unanimous vote, recently authorized the awarding of a contract to the Raymond Concrete Pile Company for construction of a 1,200 foot pier, 494 feet wide, at a new municipal grain elevator. The cost will be $680,000.

Although the bond issue of $5,000,000 voted by the city at a special election in February included not only a grain elevator, but also separate additional projects—marginal wharves, a pier and warehouses—it was decided to hold up the latter two of these three developments temporarily, because of the likelihood that the city would obtain a long-term lease on the Army Base warehouses and piers. So a contract was awarded A. M. Crain & Company for construction of the elevator, at a cost of $639,-000 and a later contract was entered into with the Raymond Concrete Pile Company for construction of the marginal wharves and jetties.

Grain Elevator, Baltimore, Md.—The Pennsylvania Railroad completed and had in full operation by November 15 the $5,500,000 grain elevator it had had under construction for some months. This addition to the company's waterfront facilities of Baltimore, Md., increases its grain handling capacity to 4,250,000 bushels. The enlargement has a capacity of 1,300,000 bushels of grain in bins, the structure being of iron and concrete fireproof construction, driven throughout by electric power. Its location is on deep water where ships to 35-foot draft can enter, four ships to be loaded at one time. The hourly capacity for loading vessels is 120,000 bushels, a part of the equipment being four mechanical unloading machines which release automatically the grain door of the box cars loaded with grain. These unloading machines have an hourly capacity of 40 cars or 80,000 bushels of grain.

NEW INCORPORATIONS

Fidello Navigation Corporation, $50,000, chartered in Delaware.

Winton Navigation Corporation, $50,000, chartered in Delaware.

Hunter Navigation Corporation, $50,000, chartered in Delaware.

Charles R. McCormick Steamship Company, capital $1,500,000 incorporated at Sacramento, Cal.

The Philadelphia and Norfolk Steamship Company, capital $1,500,000, chartered under Delaware laws.

The International Steamship Company, of New York, capital $100,000, chartered under Delaware laws.

Maritime Trust Company, capital $1,000,000, divided into 1,000 shares of $100 par value and a paid-in surplus of $1,000,000; New York.

Trans-American Trading Company, of Manhattan, capital $50,000, chartered at Albany. Incorporators: R. M. Gardner, O. G. A. Hogstedt and E. T. Nappin.

Kismet Navigation Corporation, of New York, capital $50,000, chartered under Delaware laws. Incorporators: William R. Greenway, Maurice V. Geneh and W. V. Sullivan, of New York.

Coastal Steamship Corporation, of Manhattan, capital $150,000, incorporated at Albany. Incorporators: J. W. Cunningham, C. E. Goodhue and C. H. Hunter. Lampke & Stern, attorneys, 29 Broadway, New York.

F. L. Zimmerman & Company, Ltd., of Manhattan, capital $50,000, chartered at Albany, to do a ship chartering business. Incorporators: F. L. and T. E. Zimmerman and L. F. Schworm. Lampke & Steinof, 29 Broadway, attorneys.

The Delanco Construction Company, of Delanco, N. J., capital $100,000, chartered at Trenton, to do a shipbuilding business. Incorporators: Louis D. Steele, Jacob P. Schmidt, of Delanco; Ridgway Spotts, of Edgewater Park, and Norman J. Calhoun, of Camden.

The Great Northern Steamship Company, capital $500,000, of which 9,000 shares are preferred 9 per cent cumulative stock and 10,000 shares are common stock of the par value of $50, incorporated under laws of Massachusetts as a transatlantic steamship company. Incorporators: Robert E. Tucker, Ernest W. Tucker and Perley A. Hale, all of Troy, N. H.; Norman D. Tucker and Earl E. Howard, of Fitchburg, Mass.; Fred O. Howard and Edna Howard, of Boston, and Florence S. Howard, of Gardner, Mass.

FOREIGN ACTIVITIES

Port Construction, Spain.—A company has been formed in Lisbon for the purpose of constructing a port on the Peninsula on Montijo, on the opposite side of the River Tagus, to Lisbon.

Order Placed, Scotland.—Messrs. Alexander Stephen & Son, Linthouse, have secured an order for the construction of a new steamer for the Clyde Shipping Company, Glasgow. The new ship will be 250 feet long, of 1,560 tons gross and the propelling machinery will be triple expansion engines.

Clyde Shipbuilding Output, Scotland.—In October the Clyde shipyards launched half a dozen vessels of 53,670 tons—the third largest monthly total for the year. The record for the ten months consists of 107 vessels of 342,888 tons, which is less than that of the corresponding period of last year by 88 vessels of 63,107 tons, and than the highest figures on record—those of 1913—by 111 vessels of 216,946 tons.

New Liner, New Zealand.—Union Steamship Company of New Zealand is planning the immediate construction of a 600-foot Diesel liner to be operated under the British flag between British Columbia and the Antipodes. She will be the largest vessel in the Pacific Coast-Australian trade and the first Diesel passenger carrier on the Pacific. Negotiations for building the vessel are being made with a Glasgow shipbuilder.

Tanker Launched, France.—A motor-driven tanker built for the Societe Generale des Huiles de Petrole was recently launched at Mantigues (Bouches du Rhone). The vessel, intended for carriage of petrol and mazout between Marseilles and Mediterranean ports, is fitted with six tanks having a total capacity of about 600 tons. Propelling machinery consists of a semi-Diesel motor of 200 horsepower, giving a speed of 6½ knots fully loaded.

New Vessel, England.—Representatives of the Cunard Line in New York received word of the successful launching of the latest addition to the company's fleet, the Franconia. The ship, replacing one of the same name, possesses many new features for comfort and convenience of passengers. She is 620 feet long, 74 feet in breadth and 45 feet deep, and she has a gross tonnage of 20,000, average sea speed 16 knots. The vessel accommodates 330 first, 420 second and 1,000 third class passengers.

Successful Trials, Germany.—The Tonganjika, new Hamburg-American Line steamer, built by Messrs. Blohm & Voss, Hamburg, has completed successful trials. The ship, which has been built for the West African trade, left Hamburg on October 15 for her maiden voyage. She is 448 feet in length, 58 feet in breadth by 26 feet in depth and has a gross hold capacity of 8,537 tons. Accommodation is provided for 100 first class passengers, 80 second class and 100 steerage. The propelling machinery consists of four steam turbines, developing 3,700 indicated horsepower and giving a speed of 12 knots.

Ore Carrier Launched, Sweden.—The motor ore-carrier Luossa was recently launched from the yard of Gotaverken, Gothenburg, and is one of a number of such vessels which are under construction for the Grangesberg-Oxelosund Company. She is 385 feet in length, with a beam of 53 feet 5 inches and a molded depth of 34 feet and the deadweight capacity is 8,200 tons on 25 feet draught. The propelling machinery consists of two Burmeister and Wain type six-cylinder Diesel engines, each of 1,300 indicated horsepower. On the day she was launched a sister-ship, the Lulea, also built by Gotaverken, ran her trials.

Trial Trip, Montrose, Scotland.—The single screw cargo steamer S. S. No. 93, built by the London & Montrose Shipbuilding & Repairing Company, Ltd., for Messrs. Llewellyn, Merrett & Price, Ltd., of Cardiff, ran her official trials successfully; the speed obtained being a knot and a half in excess of the contract. She is of the raised quarter deck type with engines placed aft and is designed to carry 1,050 tons of cargo. The vessel was constructed for the owners' special trade.

Norris R. Sibley Goes to London Steam Turbine Co.

NORRIS R. SIBLEY, who has been in charge of the Westinghouse Electric & Manufacturing Company's marine department in New York for several years, has resigned to become New York district manager for the London Steam Turbine Company of Troy, N. Y.

Mr. Sibley has served as assistant and chief engineer in several of the lines of the

Norris R. Sibley

merchant marine, including the American Line (International Merchant Marine Company), Clyde Line, Mallory Line, Southern Pacific Company (Morgan Line), Panama Line (Panama Railroad), Lukenback Line, Benvenue Granite Company, and Metropolitan Dredging Company. For a time he covered the marine field for the *New York World*, the *New York Herald*, and the *Sun* Press Bureau and assisted in compiling "The Blue Book of Facts," a book on marine engineering.

After leaving the United States Army Transport Service in 1918, Mr. Sibley became connected with the Westinghouse Electric & Manufacturing Company. He served as guarantee engineer on the steamship *Westwood*, and the steamship *Agawam*, the first fabricated ship in the world. He was also the Westinghouse representative at the plant of the Submarine Boat Corporation, where he supervised the installation of propelling equipment on vessels built at those yards.

He is an alumnus of the Massachusetts Nautical School, a member of the National Marine League, and various marine engineering associations. Mr. Sibley's long experience in the steam turbine field well qualifies him for his new work. His office will be in New York City.

TRADE PUBLICATIONS

Concentration Salinity Indicators.—The elimination of salt from boiler feed water, particularly in the case of the modern watertube boiler with its high steaming capacity, led to the development of an electrical device by Leeds & Northrup Company, Philadelphia, Pa., in co-operation with the Babcock & Wilcox Company, New York, for determining the degree of salinity in boiler feed water. This instrument is also used for the accurate measurement of the salinity of condensates, distillates, evaporator brine and the like. Complete details are given in a booklet which was distributed at the Marine Exposition.

Monel Metal in Service at Sea.—For a number of years before the recent war the United States Navy had been developing applications of Monel metal and had in many instances substituted it for other metals previously thought best under destructive forces. A few of the larger marine equipment manufacturers worked along similar lines. It has gradually been adopted to use in an almost endless variety of marine applications. A description of the metal and its many uses aboard ship are described in a pamphlet issued by the International Nickel Company, New York.

The Manufacture of Condenser Tubes.—In a booklet issued by the Chase Metal Works, Waterbury, Conn., complete details of the manufacture of condenser tubes are given, starting with a general outline of the three processes of producing tubes; the piercing process, the cupping process and the cast shell method. The properties and specifications and the causes of condenser tube failures are given, as well as the results of the study of factors controlling grain size of Admiralty tubes. The remainder of the booklet includes details of the physical requirements of the tubes, the method of test and inspection, as well as the use and care of condenser tubes in service.

Foster Waste Heat Type Superheaters.—Superheaters of the waste type for marine boilers have been installed in the ships of all nations. Details of such installations with complete descriptions of the superheaters are given in a bulletin issued by the Power Specialty Company, of New York. Thermometers and soot blowing apparatus with suitable safety valves for the superheaters are included. Operating records of superheaters on various ships and a list of ships equipped with Foster superheaters with their principal machinery details are also stated. Concluding sections give tabulated data on the properties of steam, fuel oil, steam pipe capacities and the like.

Duraloy.—Bulletin No. 221, of the Cutler Steel Company, Pittsburgh, Pa., contains a general description of the metal Duraloy, which has properties of resistance to oxidation, corrosion and abrasion. Duraloy is a chromium iron alloy developed as a low cost alloy to resist oxidation. It can be supplied in castings, bars, sheets and in rolled form responds to heat treatment in a manner similar to alloy steels. The pamphlet outlines the machining qualities, welding qualities and the resistance of this metal to heat, corrosion and the like.

EXETER ROTARY PUMPS

FEUERHEERD PATENTS

"A ROTARY pump combining the advantages of the centrifugal and reciprocating types. Two rotors of simple and rugged construction, each supported on its own bearing, properly lubricated and remote from the liquid being pumped.

Rolling action between rotors minimizing wear, decreasing replacement and maintenance cost.

Straight line flow of liquid resulting in high efficiencies.

No eccentric action.

The Exeter pump is self-priming, direct, acting with uniform flow. It can be arranged to operate with any form of drive,—electric motor, vertical steam engine, turbine, gas or oil engine. In capacities up to 200 GPM it operates at speeds to allow for direct connection to motors, eliminating gears and resulting in compact silent running unit.

It is particularly adapted for marine use for the following services: Cargo pump on tankers, ballast, fire and bilge, fuel oil transfer, oil supply to burners, lubricating oil, fresh water and sanitary. Manufactured either in cast iron, all bronze, or bronze fitted."

ARTMENT

Who wants these boats?

MARINE EQUIPMENT

Floating Equipment located in the Philippines and Alaska is offered for sale by sealed bid on December 20th

THERE are 22 boats in all, consisting of Gasoline and Steam Launches, a Yacht, Transport, Barge, two Yawls, two Sub-Chasers and two Distribution Barks. Seven of these boats are in poor condition, but the remainder are in fair or serviceable condition. This equipment is located and designated as follows:

Manila, P. I.—Steam Launch, "Chicago," length 85′, wood; Steam Launch, "New Orleans," length 86′, wood; Steam Launch, "Peterson," length 57′ 4″, wood; Gasoline Launch, "Hugh McGrath," length 35′, wood; Steam Yacht, "El Aquila," 185′, steel; Steam Launch, "Louisville," length 72′, wood; Steam Launch, "Reilly," length 78′, wood; Army Transport, "Warren," length 370′ 7″, steel; Steam Launch, "Bangor," length 84′, wood; Steam Launch, Florida, length 71′ 6″, wood; Steam Launch, "Missoula," length 86′, wood; Steam Launch, "Rochester," length 69′, wood; Sub-Chaser, V-11, length 110′, wood.

G-E MARINE EQUIPMENT TO MEET YOUR REQUIREMENTS:

- Electric Drive for Motorships
- Turbine-electric Drive
- Marine Geared Turbines
- Electric Drive for Auxiliaries

Don't Pipe Steam to the Ship's Roof

Imagine a factory with steam-driven machinery on the roof, steam pipes exposed and uncovered, engine room apparatus installed in a small space and inaccessible, and pipes, valves, and fittings adding steam losses by leaks and radiation. Such a plant would resemble a ship with steam-driven auxiliaries.

It has been proved that electricity is transmitted and applied more economically and with greater reliability than any other form of power. And today there is electrical apparatus built for service on the sea.

The General Electric Company can supply auxiliary marine power plant equipment, enclosed ventilated motors and special control for below-deck auxiliaries, waterproof motors and control for use on deck, marine searchlights, and other auxiliaries. It's all designed for severe marine conditions.

Full speed through the storm

Returning from a voyage to Brazil in September, 1922, the U. S. S. Maryland ran at full speed through a severe gale, the wind reaching 75 miles an hour, and heavy seas pouring over her decks.

While full credit is given her new electric drive, this noteworthy performance would not have been possible if the power plant, including the Anaconda condenser tubes, had not been absolutely dependable.

Anaconda condenser tubes are dependable because of their physical soundness, correct composition and uniform microscopic structure. Embodying a superior quality which is the result of more than a century's technical and mechanical development, Anaconda condenser tubes are used in large quantities by the U. S. Navy and the foremost American ship operators.

America's Greatest Ship
—the Leviathan—
is Columbian Equipped

The stupendous task of repairing and equipping the mammoth *Leviathan* calls for the finest materials made. Hence, Columbian—the only rope containing the famous red, white and blue *Tape-Marker* Guarantee—has been selected by the Newport News Shipbuilding and Dry Dock Company for this important work.

Columbian *Tape-Marked* Pure Manila Rope is unequalled for durability, long service, and economical operation. That is *why* it is selected for use at the foremost dry docks, shipyards, and on board modern vessels where "first quality" is a pre-requisite.

The genuine Columbian can always be identified as "the Guaranteed Rope" by its red, white and blue *Tape-Marker* bearing the significant words "Guaranteed Rope, made by Columbian Rope Co., Auburn, N. Y." This marker is placed in one of the strands as a protection for both the buyer and manufacturer. Look for it when making your next purchase of rope.

Jobbers and Dealers:—It pays the mariner to use Columbian, and it pays *you* to sell it to him. Write today for catalogue and price list.

Motorship "La Paz" of the Pacific Steam Navigation Company.

De Laval Oil Purifier is saving oil and protecting engines of motorship "La Paz"

The motorship fleet of the Pacific Steam Navigation Company was planned to transport cargo at the lowest possible cost per ton mile. Few, if any, items of design or equipment which contribute to a lower operating cost for the motorship were overlooked.

On each of these motorships, as on many others, a De Laval Oil Purifier has been installed. With this machine sludge is centrifuged out of the crank-case oil almost as fast as it is formed. As a result bearing wear is greatly reduced and the engines will, without a doubt, give more years of service with less expense for maintenance and overhauling.

By constantly removing impurities from lubricating oil, the De Laval Purifier also effects a great reduction in lubricating costs. The same oil is kept in the system indefinitely, the only replacement being that required to make up for losses by decomposition, evaporation and leakage. No oil need ever be taken out of the system.

No wonder that the Harland & Wolff Shipbuilding Company, builders of the "La Paz" and other vessels of the Pacific Steam Navigation Company's fleet, have in the past two years installed 47 De Laval Purifiers on various vessels building in their yards. The records of other British and American yards also show that De Lavals are now considered as necessary auxiliaries in the engine room of the Diesel or turbine-driven ship.

Mail the coupon for further information regarding ships of either class.

Wheeler Sextuple Effect Evaporator

Capacity, 120 tons of distilled water a day, operates on exhaust steam and carries a vacuum on the last effect. **Copper, Brass and Bronze used throughout.**

This Evaporator Unit is 100% Copper, Brass and Bronze

Not a pound of iron in it.

For marine service, it is perfect—compact, non-corrodible, and 30 per cent lighter than if iron castings had been used.

The shell is of heavy sheet Copper. The tube header, floating head and cover plate are Bronze. The tubes are of seamless drawn Copper expanded into the tube sheets. All feed piping and brine connections are of Brass and Bronze.

* * *

Since the first Bronze-beaked Phoenician galley breasted the seas, Copper metals have been intimately associated with the development of shipping and the advancement of naval design.

Copper, Brass and Bronze are the standard salt water metals.

REMEMBER

Regular profits are assured by careful, sound investment. Crandall Dry Docks are based on sound engineering design and the combined experience of three generations. As a result the initial cost and operating expense are much lower per ton of lifting capacity than those of any other types. Thus you are assured of maximum return on the invested capital.

We will be glad to inform you of the locations of Crandall Dry Docks and forward descriptive pamphlets illustrating them.

When RELIABILITY is an absolute essential

The condition of a cargo of perishable foodstuff when it reaches port, depends to a large degree, upon the reliability of the refrigerating machine. The owner's chances of making or losing thousands of dollars, hinges upon the performance of the equipment which is furnishing the necessary refrigeration.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-six years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Hundreds of vessels now plying the seven seas employ York Mechanical Refrigeration to the satisfaction of their Engineers and Owners. We invite all shipping interests to investigate the York Systems of Marine Refrigeration, and believe it will prove profitable to them.

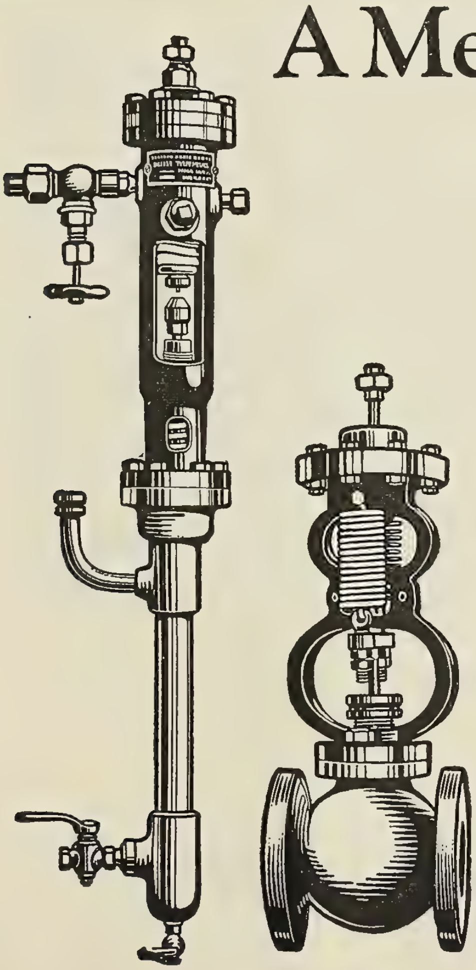
A Means of Economy at Sea



Here's a simple device which marine engineers have been quick to adopt because of its steam saving.

After all, what you ask of your pump is that it bring the pressure to a certain point and then stop its work until that pressure drops, after which, it should resume again and automatically maintain the pressure at the proper point.

The Todd Differential Pump Governor does just this. When the pump's job is done it uses no more steam, wastes no more power until fresh effort is required of it.

A post card will bring you full details of the Todd Governor.

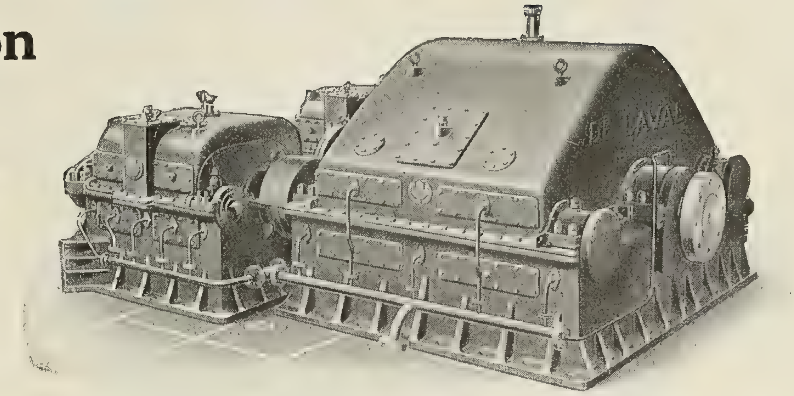
PUMP GOVERNOR

De Laval Double Reduction Gears Give Satisfaction



De Laval 6000 HP. double marine reduction gear for 110-RPM. propeller speed, supplied for installation in three twin-screw transports.

THE success of De Laval gears is due to our long experience in the design of such gears and our careful and painstaking methods of manufacture. De Laval gears are cut on gear cutters specially designed and built by the De Laval Company, as our experience has demonstrated that the ordinary commercial helical gear cutter will not permit the degree of accuracy necessary for high speed gears. All parts are made to limit gages and are interchangeable.

State type and size of vessel in which you are interested, and we shall be glad to send more detailed information with our publication, M-46, and a list of vessels using De Laval Geared Turbines.

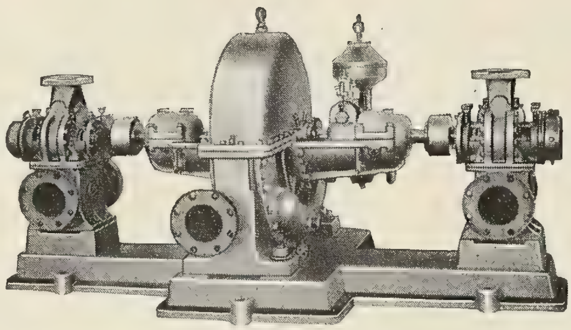
Northern Rotary Pumps For Marine Service



One of Two Dual Pump Units in Service on Steamship Leviathan. Used on Foamite Firefoam.

Small Space on Shipboard

is one of the primary features of Northern Rotary Pumps that are making them steadily more popular for marine service. In spite of the fact that these pumps deliver oils and water against pressures of 300 pounds and over, they take up surprisingly small space on board ship.

Lubricating oil service, fuel oil, boiler feed, bilge and sanitary, fresh water, standby fire, main cargo transfer,—are now common duties of these pumps on ships and shore service.

Furnished direct-shaft connected to common speed electric motors and slow-speed turbines for capacities ranging from 4 to 2,000 gallons per minute.

The Pipe Is Out of Line — BUT

The GOETZE GASKET Is Holding Tight

Even if the pressure is high with a poor job in pipe fitting you can make any joint tight with a Goetze Gasket.

The resilient deep corrugation in the copper or other metal and the spun asbestos rings take care of that. They remain in perfect contact with the flange surface, regardless of expansion and contraction.

Goetze Gaskets last as long as the pipe line. You can remove them and re-use them with assured tightness.

We are ready now to convince you that Goetze Gaskets, Goetzerit Sheet Packing and Goetze Valve Discs are unbeatable in any service. A 90 days' free trial allowed.

PROFESSIONAL DIRECTORY

CONSULTING AND MARINE ENGINEERS, NAVAL ARCHITECTS MARINE SURVEYORS, PATENT ATTORNEYS, ETC.

Positions Vacant **Get Together Department** Positions Wanted

USED MARINE EQUIPMENT

Classified Advertisements—Help and Situation Wanted advertisements appearing in the "Get Together Department," 5c. a word an insertion. Minimum charge $1.00 for each insertion. For Sale advertisements $6.00 a column inch (1" by 3½" wide). Any number of inches may be used. Copy must be in this office by the 10th of each month preceding to insure insertion in the issue.

HELP WANTED

WANTED—Draftsman, thoroughly familiar with the design and construction of 200 to 300 ft., steel, moderate draft, fast combination passenger and express, and freight river vessels, with steam or Diesel Drive. Must be familiar with speed, stability, weight, and other calculations as well as construction, details and arrangements. State pay expected and full experience, education, and send examples of work in first reply. Ralph E. Winslow, River St., Atlantic, Mass.

POSITION WANTED

YOUNG Scotchman, 22½ years, desires a position as sea-going Junior Engineer. Having six years' practical engineering experience, also having College certificates in engineering drawing. Andrew Brown, 802 South Pershing Ave., Indianapolis, Ind.

SHIPYARD EXECUTIVE—Fifteen years' experience both technical and practical, graduate engineer, will consider change to allied line. Personal interview desired. Address Box 146, Marine Engineering, Woolworth Building, New York City.

DESIGNER AND ESTIMATOR, graduate naval architect, with twelve years' practical experience as draftsman, designer, and estimator, latter part in full charge of all technical and inspection work steel shipyard, also some experience wood construction. Will consider partnership consulting work, or responsible position offering reasonable permanence. Address Box 147, Marine Engineering, Woolworth Building, New York City.

GRADUATE Naval Architect with 12 years' practical experience, experienced in motorship design and operation, desires connection where such experience can be utilized. Address Box 148, Marine Engineering, Woolworth Building, New York.

EDUCATIONAL

POWERING OF VESSELS. A Practical Course of Instruction by Correspondence. Address for particulars and terms, Box C. I. D., "MARINE ENGINEERING," 34 Victoria Street, London, S. W. 1, England.

Let us help you find the right man or position.

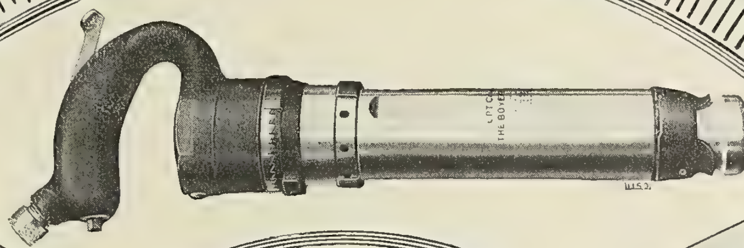
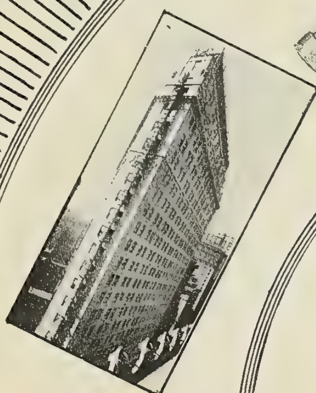
BOYER-SKYSCRAPER BUILDER





Above—Munson Building, N.Y.C. Contains 71,000 Boyer-driven rivets.

Above—Bush Building, N.Y.C. Contains 65,000 Boyer-driven rivets.

THROUGHOUT the notable career of Post & McCord, structural steel specialists, New York, the Boyer Riveting Hammer has built a lasting reputation with them and their riveters.

Illustrated are but a few of the many skyscrapers Post & McCord have built with the aid of the Boyer.

With its speed of 850 to 2100 blows per minute, great driving power, ease of control and operating economy—the Boyer drives rivets, *all perfect, at least cost per rivet driven.*

What is your per-rivet-driven cost? Lower it by making Boyers your standard as have Post & McCord.

Ask for Bulletin 810.

ALPHABETICAL INDEX TO ADVERTISEMENTS

When a flying boat needs a *lift*

In the hangars of the Aeromarine Airways, Inc., at Keyport, N. J., expert mechanicians are ever watchful of the details which assure the *safety*, *speed*, and *comfort* of travel through the air, enjoyed by those who fly in Aeromarine aircraft.

THE SHEPARD ELECTRIC
LIFTABOUT

They have an ever-ready "helper" in a Shepard Electric *LiftAbout* which always provides a *steady, safe, speedy* "lift" in handling aircraft within the hangar.

It seems that this powerful little hoist knows no lifting problems that it cannot solve.

In your plant or yard, there may be a place where our *LiftAbout* is "just what you've long needed." It will bring to you *good hoisting service at a remarkably low cost.*
